X1.4.1 The cable splicing method presented in this guide uses a compression-crimp, tubular-metal connector for butt connection of cable conductors in conjunction with the use of shrinkable tubing as both the conductor reinsulating material and overall cable sheath (jacket) replacement. This guide is considered the most effective procedure for the greatest number of applications of cable materials.

X1.4.2 Although other insulating systems are available and considered appropriate for particular applications, they have not been addressed in detail in this guide. The use of various layers of insulating materials, such as shrinkable-tubing, tape, or molding compounds require varying levels of skill, differences in time, and relative cost. The six splicing systems evaluated were:

X1.4.2.1 Cold shrink.
X1.4.2.2 Heat shrink.
X1.4.2.3 Molded—vulcanized.
X1.4.2.4 Molded—resin, room temperature cure.
X1.4.2.5 Molded—resin, heat cure.
X1.4.2.6 Tape.

X1.4.3 The most significant factor that the shipbuilder must address is that the choice of a splicing system must be compatible to both the application/environment and cable jacket material. Information furnished in Tables X1.1-X1.3 provide comparisons for the various splicing systems to application factors, compatibility to cable-jacketing materials, and environment/location of the splice.

X1.4.3.1 Table X1.1 shows compatibility of splicing systems to the various types of cable jacket materials found in shipboard applications.

X1.4.3.2 Acceptability of the six splicing systems with regard to environmental or application location is shown in Table X1.2.

TABLE X1.1 Splicing System—Application/Environment
X1.4.3.3 Table X1.3 evaluates application factors for the six systems and offers a comparison between systems as to the required skill level of the installer and the time required for installation.

X1.4.4 Shrink Tubing Methods—Shrinkable tubing materials are recommended for the vast majority of cable splice applications. These materials provide the electrical and mechanical properties equivalent to the original cable conductor insulation and jacketing material.

X1.4.4.1 The addition of a sealant is felt necessary since the cable’s jacket may be nonuniform, damaged, or scratched. Deviation from eccentricity or small paths for moisture could lead to splice failure; therefore, the sealant provides an additional safety factor considered necessary. The addition of sealant to the area of overlap on the original cable jacket during splice installation is required for either heat-shrink or cold-shrink tubing.

X1.4.5 Molding Compounds Methods—A variety of materials that includes rubber-based compounds, epoxies, silicones, and polyurethane are available for molded-type cable splices. Vulcanized splices are made with molding presses and require the use of heat. Ambient-temperature cured materials are sometimes referred to as “room temperature” cure since no external heat is applied for the polymerization reactions.

X1.4.5.1 For the marine environment, molded splices mainly are used for outboard, weather-exposed, or underwater applications. This type of splice is molded in matched metal molds, which may be attached to heating platens to expedite forming. For molded splices, the manufacturers’ recommendations on surface cleaning and preparation of the casting compounds and primer should be followed explicitly.

X1.4.6 Tape and Coating Compounds—Taping is more skill/workmanship intensive as compared to the shrinkable tubing or molding compound methods. The basic types of tapes and their primary function is as follows:

X1.4.6.1 Insulating and binder-type tapes are pressure-sensitive tapes used as primary insulation directly over the connector/conductor and as a binder tape over the conductors for cables with two or more conductors. These tapes have a dielectric strength that permits use as a primary insulator over base connectors or conductors.

X1.4.6.2 Filler tape is used both to fill the indents on large connectors and to provide a smooth taping surface over which the cable jacket material can be applied. These tapes have a dielectric strength that permits use as a primary insulator over base connectors or conductors.

X1.4.6.3 Outer sheathing tape is a pressure-sensitive vinyl tape used as sheathing over the filler tape. Sheathing tape is a relatively heavy tape that is used to cover the splice area and provides protection against abrasion and wear.

X1.4.6.4 Care should be exercised to keep adhesive tapes (insulating, binder, and sheathing) clean since they are difficult to remove if they become contaminated with dirt or other foreign materials.

Critical shelf life is defined as less than two years.
to apply when the adhesive becomes coated with dirt. Contaminants also will cause degradation to the tape’s electrical properties. All tapes must be applied tightly and smooth and should be applied such that the buildup to reinsulate the individual conductor or produce the overall splice is of uniform cross section.

X1.4.6.5 To complete a tape splice, a coating material, normally a liquid cement compound, shall be brushed on in several thin coats to provide overall seal to the splice.
Standard Specification for Stuffing Tubes, Nylon, and Packing Assemblies (Metric)\textsuperscript{1}

This standard is issued under the fixed designation F 1836M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (\(\epsilon\)) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the general requirements for nylon stuffing tubes and packing assemblies. Nylon stuffing tubes are intended for making electric cable penetrations in marine shipboard enclosures for electrical equipment. The following types are suitable for both thin-wall enclosures up to 5 mm (\(\frac{3}{16}\) in.) thick and thick-wall enclosures, bulkheads, and decks of 5 to 19 mm (\(\frac{3}{16}\) to \(\frac{3}{4}\) in.) thick.

1.2 This specification does not cover metal stuffing tubes.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to its use.

2. Referenced Documents

2.1 ASTM Standards:
D 2000 Classification System for Rubber Products in Automotive Applications\textsuperscript{2}
D 4066 Specification for Nylon Injection and Extrusion Materials (PA)\textsuperscript{3}

2.2 NEMA Standards:
Standard 250 Enclosures for Electrical Equipment (1000 V Max)\textsuperscript{4}

2.3 ASME Standard:
ASME B1.1 Unified Inch Screw Threads (UN and UNR Thread Form)\textsuperscript{5}

2.4 IEC Standard

3. Terminology

3.1 Definitions of Terms Specific to This Standard:
3.1.1 nylon stuffing tube, \(n\) — a marine electrical fitting used for the sealing of cable penetration into shipboard enclosures while maintaining or exceeding the degree of protection for which the enclosure is rated.
3.1.2 packing assembly, \(n\) — the compressible insert for the nylon stuffing tube. It consists of one neoprene bushing and three nylon washers.
3.1.3 enclosure, \(n\) — an electrical panel, cabinet, junction box, light fixture, electrical equipment, control box, or panel.

4. Classification

4.1 Nylon stuffing tubes shall be of the following types (see Fig. 1):
4.1.1 Type 1—straight— Unified Form Thread.
4.1.2 Type 2—90\(^o\) — Unified Form Thread.
4.1.3 Type 3—NPT—American Standard Pipe Thread.
4.1.4 Type 4—Y—Unified Form Thread.

5. Ordering Information

5.1 Orders for stuffing tubes under this specification shall include the following:
5.1.1 Type (see 4.1).
5.1.2 Part number (see Table 1).
5.1.3 Packing assembly size (see Fig. 2 and Table 2).
5.1.4 The O-ring included in the stuffing tube assembly has a finite shelf life. If the stuffing tube assembly is used after the shelf life has expired, the O-ring should be replaced, using the appropriate size listed in Table 1.

6. Materials and Manufacture

6.1 Materials:
6.1.1 Polyamide (nylon) molding plastic material shall be Group 1, Class 8, Grade 1 in accordance with Specification D 4066.
6.1.2 Synthetic rubber (neoprene) shall be in accordance with Classification D 2000, M2, BC, 410, A14, B14, C12, and F19.

6.2 Manufacture:
6.2.1 Molded nylon parts, such as body, washers, locknut, and cap, shall meet the requirements specified herein.

---
\textsuperscript{1} This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.10 on Electrical.
\textsuperscript{3} Annual Book of ASTM Standards, Vol 09.02.
\textsuperscript{4} Available from the National Electrical Manufacturers Association, 1300 N. 17th St., Suite 1847, Rosslyn, VA 22209.
\textsuperscript{5} Available from the International Electrotechnical Commission, 3 rue de Varembe, Case postale 131, CH-1211, Geneva 20, Switzerland.
\textsuperscript{6} Available from American Society of Mechanical Engineers (ASME), ASME International Headquarters, Three Park Ave., New York, NY 10016-5990.
6.2.2 Threads shall be unified form UN 2A or 2B or taper pipe thread (NPT) as specified in ASME Standard B1.1.

6.2.3 Neoprene parts, such as bushing and plug, shall meet the requirements specified in Classification D 2000, and when assembled in a stuffing tube, shall meet the performance requirements specified herein.

7. Other Requirements

7.1 Performance Requirements:

7.1.1 Vibration resistance—When stuffing tubes are tested as specified in 9.1, there shall be no evidence of cracking or loosening of parts.

7.1.2 Ruggedness—When stuffing tubes are subjected to a mechanical abuse test as specified in 9.2, there shall be no cracking, breaking, distortion, or damage to the sample.

7.1.3 Effectiveness of seal—When stuffing tubes are tested as specified in 9.3, there shall be no evidence of leakage through or around the stuffing tubes.

8. Workmanship, Finish, and Appearance

8.1 Stuffing tubes shall be free from warp, cracks, chipped edges or surfaces, blisters, uneven surfaces, scratches, dents, and heat marks. They shall be free from fins, burrs, and unsightly finish caused by chipping, filing, or grinding without subsequent buffing or polishing. All molded nylon parts shall
be cleaned thoroughly of annealing mediums. Packing assemblies shall be free of voids, pin holes, flash, or other imperfections, that may impair their serviceability.

### 9. Test Methods

9.1 Conformance testing of a random sample may be requested by the purchaser to verify that selected performance characteristics specified herein have been incorporated in the stuffing tube design and maintained in production.

9.1.1 Vibration—The stuffing tubes shall be subjected to vibration testing as specified in IEC Standard 68-2-6. The following details shall apply:

9.1.1.1 The stuffing tubes shall be complete with O-rings and 1- to 2-m (3- to 6-ft) lengths of cable of appropriate size.

9.1.1.2 The free end of the cables shall be secured to prevent excessive cable whipping action during test.

<fig:2 Typical Packing Assembly>

A See Table 2 size selection.
9.1.1.3 Tests are to be carried out in three perpendicular planes.

9.1.1.4 Duration of the test for no resonance condition shall be 90 min at 30 Hz. Duration at each resonance frequency at which \( Q > 2 \) is recorded. It is recommended as guidance that \( Q \) does not exceed 5.

9.1.1.5 Test range shall be:

- \( 2^{60.3} \) to 13.2 Hz – amplitude \( 6^{1} \) mm
- 13.2 to 100 Hz – acceleration \( 6^{7} \) g

9.1.1.6 Nonconformance to the requirements of 7.1.1 shall be cause for rejection.

9.2 Mechanical Abuse Test:

9.2.1 Mechanical abuse test shall be conducted on the sample stuffing tubes assembled with packing assembly on the end of a 2-m (6-ft) length of electrical cable of appropriate size.

9.2.2 The stuffing tube shall be allowed to swing on a radius, while suspended by the electrical cable, from a vertical surface and strike against a vertical flat steel plate on that surface. The vertical distance through which the stuffing tube is allowed to fall shall be 1.5 m (5 ft), and the number of impacts shall be ten.

9.2.3 The stuffing tube shall be disassembled and examined. Nonconformance to the requirements of 7.1.1 shall be cause for rejection.

9.3 Level of Effectiveness—A complete stuffing tube with O-ring installed and properly assembled to a cable or with a plug installed shall conform to the performance requirements of NEMA 250. The NEMA enclosure-type designation (4, 4X, 6, 6P) shall establish the appropriate environmental capability (see NEMA 250) required of the installed stuffing tube assembly.

9.3.1 Nonconformance to the requirements of 7.1.3 shall be cause for rejection.

10. Inspection

10.1 Visual and Dimensional Examination—Samples shall be examined visually to verify that the materials, design, construction, physical dimensions, marking, and workmanship are as specified in the applicable requirements.

11. Certification

11.1 Plastic Material Certification—Material certification shall be required from the manufacturer of the plastic material to ensure the material was manufactured, sampled, tested, and inspected in accordance with Specification D 4066. Material identity, traceable to this certification, shall be maintained throughout the manufacturing process.

11.2 Cure date information of all rubber products shall be recorded on the manufacturer’s certificate of conformance. The year and quarter of manufacture shall be listed.

---

**Note 1**—Packing assembly selection requires that the packing bushing inner diameter (\( D \)) be equal or slightly larger than the cable maximum diameter (DIA).

**Note 2**—I.D. column indicates the bushing inner diameter.
11.3 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

12. Product Marking

12.1 Each nylon stuffing tube component body, locknut, cap, bushing, and washers shall have permanent marking in 3-mm (1/8-in.) high raised letters as size permits. For size-sensitive components, reduced marking is acceptable. Marking shall indicate the following:

12.1.1 Manufacturer’s name or trademark and tube size.

12.1.2 Identification markings of prior or superseded specifications or government drawings. These markings are acceptable. New molds or molds that require rework shall contain, if required, the ASTM designation number of this specification and part number. The location of the ASTM marking shall apply to the stuffing tube only and be located on the stuffing tube body. Marking in accordance with 12.1.1 shall apply to all stuffing tube components.

13. Packaging

13.1 Packaging shall be manufacturer’s commercial practice and shall be sufficient to afford adequate protection against deterioration and physical damage during shipment from the manufacturer or supplier, or both, to the using activity.

Note 1—Bulk packaging for nylon stuffing tubes; unit packaging for packing assemblies.

14. Quality Assurance

14.1 Responsibility for Inspection—Unless otherwise specified in the contract or purchase order, the manufacturer is responsible for the performance of all inspection requirements as specified herein. Except as otherwise specified in the contract or purchase order, the manufacturer may use his own or any other facilities suitable for the performance of the inspection requirements specified.

14.2 Responsibility for Compliance—All items must meet all the requirements of Section 7. The inspection set forth in this specification shall become a part of the manufacturer’s overall inspection system or quality program. The absence of any inspection requirements in the specification shall not relieve the manufacturer of the responsibility of assuring that all products or supplies submitted to the customer for acceptance comply with all the requirements of the contract. Sampling in quality conformance does not authorize submission of known defective material either indicated or actual, nor does it commit the purchaser to acceptance of defective material.

15. Keywords

15.1 cable entry seal; cable penetrator; stuffing tube

**SUPPLEMENTARY REQUIREMENTS**

The following supplementary requirements are applicable to DoD procurements and shall apply only when specified by the purchaser in the contract or purchase order.

S1. Referenced Documents

S1.1 Military Specifications:
MIL-S-901 Requirements for Shock Tests, H.I. (High-Impact), Shipboard Machinery, Equipment, and Systems

S2. Shock Tests

S2.1 Stuffing tubes shall be subjected to the high-impact shock test for Grade A, Type A, Class I equipment as specified in MIL-S-901. The details specified in 9.1 and 9.2 shall apply. Nonconformance to the requirements of S2.2 shall be cause for rejection.

S2.2 Examination After Shock Tests—When stuffing tubes are tested as specified in S2.1, there shall be no evidence of cracking, breaking, distortion, or loosening of parts.

S3. Level of Effectiveness (See 9.3)

S3.1 Submersible and Open Submersible—Equipment shall be submergence tested to a depth of 4.5 m (15 ft) at 44.8 KPa (6.5 psi) for 24 h. Nonconformance to the requirements of 7.1.3 shall be cause for rejection.

S3.2 Examination After Immersion—Failure for stuffing tube to operate satisfactorily shall be cause for rejection. For enclosures including terminal boxes, as revealed by subsequent disassembly and examination, leakage of water into any part of the enclosure shall be cause for rejection.

S4. Packaging

S4.1 Preservation, Packing, and Marking—Preservation and packing may be commercial. Marking information shall include cure date, shelf life, and expiration dates of rubber products.
Standard Specification for
Heat-Shrink Cable Entry Seals (Metric)¹

This standard is issued under the fixed designation F 1837M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the general requirements for heat-shrink cable entry seals. Cable entry seals are intended for making electrical cable penetrations into connection boxes, bulkheads, or other enclosures. These devices are suitable for both thin wall enclosures up to 5 mm (3⁄16 in.) thick and thick-wall enclosures of 5 mm to 19 mm (3⁄16 in. to 3⁄4 in.) thick.

1.2 Cable entry seals shall have factory-applied adhesive that provides the seal to wire and cable jackets.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to its use.

2. Referenced Documents

2.1 ASTM Standards:
D 149 Test Method for Dielectric Breakdown Voltage and Dielectric Strength of Solid Electrical Insulating Materials at Commercial Power Frequencies²

D 570 Test Method for Water Absorption of Plastics⁴
D 635 Test Method for Rate of Burning and/or Extent and Time of Burning of Self-Supporting Plastics in a Horizontal Position⁴
D 747 Test Method for Apparent Bending Modulus of Plastics by Means of a Cantilever Beam⁴
D 792 Test Methods for Density and Specific Gravity (Relative Density) of Plastics by Displacement⁴
D 2240 Test Methods for Rubber Property—Durometer Hardness³

D 2671 Test Methods for Heat-Shrinkable Tubing for Electrical Use⁵
D 2863 Test Method for Measuring the Minimum Oxygen Concentration to Support Candle-Like Combustion of Plastics (Oxygen Index)⁶
D 3149 Specification for Crosslinked Polyolefin Heat-Shrinkable Tubing for Electrical Insulation⁵
D 4572 Test Method for Rubber Chemicals, Wet Sieve Analysis of Sulfur³
D 4732 Specification for Cool-Application Filling Compounds for Telecommunication Wire and Cable

2.2 ASME Standard
ASME B1.1 Unified Inch Screw Threads (UN and UNR Thread Form)⁷

2.3 NEMA Standards:⁵
NEMA 250 Enclosures for Electrical Equipment (1000 Volts Max)⁸

2.4 IEC Standard:

3. Terminology

3.1 Definitions of Terms Specific to This Standard:
3.1.1 heat-shrink cable entry seal, n—heat-shrinkable tube making a watertight, fume-tight seal where cable connections boxes, bulkheads, or other enclosures.

3.1.2 polyolefin, n—a polymer made by the polymerization of hydrocarbon olefins or copolymerization olefins.

4. Classification

4.1 Heat-shrink cable entry seals shall be of the following types:

4.1.1 Type I, standard cable entry seals for thin-wall enclosures shall consist of the three part assembly; a rigid plastic nut, O-ring, and heat-shrinkable molded area.

4.1.1.1 Type I–1, molded area configured with one opening for a single wire or cable entry.

4.1.1.2 Type I–2, molded area configured with two equal size openings to seal two wires or cables.
4.1.1.3 Type I–3, molded area configured with three equal size openings to seal three wires or cables.
4.1.1.4 Type I–4, molded area configured with four equal size openings to seal four wires or cables.
4.1.1.5 Type I–5, molded area configured with six equal size openings to seal six wires or cables.
4.1.1.6 Type I–6, molded area configured with eight equal size openings to seal eight wires or cables.
4.1.2 Type II, cable entry seal for threaded hole applications shall consist of a one-part assembly that combines a tapered national pipe thread (NPT) in rigid plastic with heat-shrinkable molded area.
4.1.2.1 Type II–1, molded area configured with one opening for a single wire or cable entry.
4.1.2.2 Type II–2, molded area configured with two equal size openings to seal two wires or cables.
4.1.2.3 Type II–3, molded area configured with three equal size openings to seal three wires or cables.
4.1.2.4 Type II–4, molded area configured with four equal size openings to seal four wires or cables.
4.1.3 Type III, right angle cable entry seal for thin-wall enclosure shall consist of a three part assembly; a rigid plastic nut, O-ring, and heat-shrinkable molded area.
4.1.4 Type IV, right angle cable entry seal for threaded hole application shall consist of a one-part assembly that combines a tapered national pipe thread (NPT) in rigid plastic with a heat-shrinkable molded area.

5. Ordering Information
5.1 Orders for cable entry seals under this specification shall include the following:
5.1.1 Part Number (see Figs. 1-6).
5.1.2 Quantity (per each part).

6. Materials and Manufacture
6.1 The rigid plastic parts shall be made from polyamide (nylon), (or polyester material, or both.) The material shall be Group 1, Class 8, Grade 1 as specified in Specification D 4066.
6.1.1 Threads shall be unified form UN 2A or 2B or taper pipe thread (NPT) as specified in ASME B1. 1.
6.2 The heat-shrinkable tubing shall be of a crosslinked polyolefin in accordance with Type III of Specification D 3149.
6.3 The adhesive shall be general purpose high-bond-strength adhesive sealant that provides stain relief and environmental sealing of heat-shrink tubing to cable jackets.

6.4 O-rings shall be made of a material conforming to Type II of Specification D 4732.
6.5 The polyolefin heat-shrinkable tubing shall meet requirements of Test Methods D 2671.

7. Other Requirements
7.1 Dimensional Requirements—Cable-entry seals shall conform to the dimensional requirements of Tables 1-6. Type I cable-entry seals are presented in Fig. 1 and Fig. 2. Type II cable-entry seals are presented in Fig. 3 and Fig. 4. Right-angle cable-entry seals (Types III and IV) are presented in Fig. 5 and Fig. 6.
7.2 Performance Requirements:
7.2.1 Vibration Resistance—When cable-entry seals are tested as specified in 9.1, there shall be no evidence of cracking or loosening of parts.
7.2.2 Ruggedness—When cable-entry seals are subjected to a mechanical abuse test as specified in 9.2, there shall be no cracking, breaking, distortion, or damage to the sample.
7.2.3 Effectiveness of seal—When cable-entry seals are tested as specified in 9.3, there shall be no evidence of leakage through or around the cable entry seals.

8. Workmanship, Finish, and Appearance
8.1 Cable-entry seals shall be free from warp, cracks, chipped edges, or surfaces, blisters, uneven surfaces, scratches, dents, and flow lines. They shall be free from fins, burrs, and from unsightly finish caused by chipping, filling, or grinding without subsequent buffing or polishing. All molded parts shall cleaned thoroughly of annealing mediums.

9. Test Methods
9.1 Conformance testing of a random sample may be requested by the purchaser in order to verify that selected performance characteristics specified herein have been incorporated in the cable-entry seal design and maintained in production.
9.1.1 Vibration—The cable-entry seals shall be subjected to vibration testing as specified in IEC Standard 68-2-6. The following details shall apply:
9.1.1.1 The cable-entry seals shall be complete with O-rings and 1 to 2-m (3 to 6 ft) lengths of cable of appropriate size.
9.1.1.2 The free end of the cables shall be secured to prevent excessive cable whipping action during test.
9.1.1.3 Tests are to be carried out in three perpendicular planes.
9.1.1.4 Duration of the test for no resonance condition shall be 90 min at 30 Hz. Duration at each resonance frequency at which Q>2 is recorded. It is recommended as guidance that Q does not exceed 5.
9.1.1.5 Test range shall be 2 ± 0.3 Hz to 13.2 Hz–amplitude ± 1 mm; 13.2 Hz to 100 Hz–acceleration ±7 g.
9.1.1.6 Nonconformance to the requirements of 7.2.1 shall be cause for rejection.
9.2 Mechanical Abuse Test:
9.2.1 A mechanical abuse test shall be conducted on the sample cable-entry seal assembled on the end of a 2-m (6-ft) length of electrical cable of appropriate size.
9.2.2 The cable-entry seal shall be allowed to swing on a radius, while suspended by the electrical cable, from a vertical surface and strike against a vertical flat steel plate on that surface. The vertical distance through which the cable entry seal is allowed to fall shall be 1.5 m (5 ft), and the number of impacts shall be ten.

9.2.3 The cable-entry seal shall be disassembled and examined. Nonconformance to the requirements of 7.2.2 shall be cause for rejection.

9.3 Level of Effectiveness—A complete cable-entry seal with O-ring installed and assembled properly and shrunk to a cable or with a plug installed shall conform to the performance requirements of NEMA 250. The NEMA enclosure type designation (4, 4X, 6, 6P) shall establish the appropriate environmental capability required of the installed cable-entry seal.

9.3.1 Nonconformance to the requirements of 7.2.3 shall be cause for rejection.

10. Inspection

10.1 Visual and Dimensional Examination—Samples shall be examined visually to verify that the materials, design, construction, physical dimensions, marking, and workmanship are as specified in the applicable requirements.

11. Certification

11.1 Material Certification—Material certification shall be required from the manufacturers of the plastic material and shirk-tubing to ensure the materials were manufactured, sampled, tested, and inspected in accordance with Specifications D 4066 and D 3149. Material identity traceable to this certification shall be maintained throughout the manufacturing process.

11.2 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met.
specified in the purchase order or contract, a report of the test results shall be furnished.

12. Product Marking

12.1 Each cable-entry seal shall be identified distinctly. The name of the manufacturer, part number, identification of this ASTM standard, and other appropriate information shall be shown thereon.

13. Packaging Requirements

13.1 The seals shall be supplied by type as specified in Figs. 1-6.

13.2 The seals shall be packaged in conformance with good commercial practice unless otherwise specified. Individual types and sizes shall be neatly bundled or boxed. The exterior shipping container shall be acceptable by parcel post or common carrier.

13.3 Each bundle or container of seals shall be identified distinctly by a tag or label. The name of the manufacturer, the part number of the seals, the quantity, and other appropriate information shall be shown thereon.

14. Quality Assurance

14.1 Responsibility for Inspection—Unless otherwise specified in the contract or purchase order, the manufacturer is responsible for the performance of all inspection requirements as specified herein. Except as otherwise specified in the contract or purchase order, the manufacturer may use his own
14. Responsibility for Compliance

—All items must meet all requirements of section 7. The inspection set forth in this specification shall become a part of the manufacturer’s overall inspection system or quality program. The absence of any inspection requirements in this specification shall not relieve the manufacturer of the responsibility of assuring that all products or supplied submitted to the customer for acceptance comply with all the requirements of the contract. Sampling in quality conformance does not authorize submission of known defective material either indicated or actual, nor does it commit the customer to acceptance of defective material.

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements are applicable to DoD procurements and shall apply only when specified by the purchaser in the contract or purchase order.

S1. Referenced Documents
S.1.1 Military Specification:
MIL-S-901 Shock Tests, H.I. (High-Impact), Shipboard Machinery, Equipment, and Systems\(^{10}\)

S2. Shock Tests
S2.1 Cable-entry seals shall be subjected to the high-impact shock test for Grade A, Type A, Class I equipment as specified in MIL-S-901. The details specified in 9.1.1 and 9.1.2 shall apply. Nonconformance to the requirements of S2.2 shall be cause for rejection.

S2.2 Examination After Shock Tests—When cable-entry seals are tested as specified in S.2.1, there shall be no evidence of cracking, breaking, distortion, or loosening of parts.

S3. Performance Requirements
S3.1 Table S3.1 establishes the physical, thermal, and chemical properties for heat-shrink tubing used in the cable-entry seal.

S4. Level of Effectiveness (See 9.3)
S4.1 Submersible and Open Submersible—Equipment shall be submersion tested to a depth of 4.5 m (15 ft) at 44.8 KPa (6.5 psi) for 24 h. Nonconformance to the requirements of 7.1.3 shall be cause for rejection.

S4.2 Examination After Immersion—Failure for cable-entry seals to operate satisfactorily shall be cause for rejection. For enclosures including terminal boxes, as revealed by subsequent

\(^{10}\) Available from the Standardization Document Order Desk, 700 Robbins Ave., Bldg. 4D, Philadelphia, PA 19111–5098.
disassembly and examination leakage of water into any part of the enclosure, shall be cause for rejection.

S5. Packaging

S5.1 Preservation, Packing, and Marking—Preservation and packing may be commercial. Marking information shall in-
Standard Guide for 
Escort Vessel Evaluation and Selection

This standard is issued under the fixed designation F 1878; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This guide covers the evaluation and selection of escort vessels that are to be used to escort ships transiting confined waters. The purpose of the escort vessel is to limit the uncontrolled movement of a ship disabled by loss of propulsion or steering to within the navigational constraints of the waterway. The various factors addressed in this guide also can be integrated into a plan for escorting a given ship in a given waterway. The selection of equipment also is addressed in this guide.

1.2 This guide can be used in performance-based analyses to evaluate:
1.2.1 the control requirement of a disabled ship,
1.2.2 the performance capabilities of escort vessels,
1.2.3 the navigational limits and fixed obstacles of a waterway,
1.2.4 the ambient conditions (wind and sea) that will impact the escort response, and
1.2.5 the maneuvering characteristics of combined disabled ship/escort vessel(s).

1.3 This guide outlines how these various factors can be integrated to form an escort plan for a specific ship or a specific waterway. It also outlines training programs and the selection of equipment for escort-related activities.

1.4 A flowchart of the overall process for developing and implementing an escort plan is shown in Fig. 1. The process begins with the collection of appropriate data, which are analyzed with respect to the performance criteria and in consultation with individuals having local specialized knowledge (such as pilots, waterway authorities, interest groups, or public/private organizations, and so forth). This yields escort vessel performance requirements for various transit speeds and conditions; these are embodied in the ship’s escort plan. When the time comes to prepare for the actual transit, the plan is consulted in conjunction with forecast conditions and desired transit speed to select and dispatch the appropriate escort vessel (or combination of vessels). A pre-escort conference is conducted to ensure that all principal persons (ship master, pilot, and escort vessel masters) have a good understanding of how to make a safe transit and interact in the event of an emergency.

1.5 This guide addresses various aspects of escorting, including several performance criteria and methodologies for analyzing the criteria, as well as training, outfitting, and other escort-related considerations. This guide can be expanded as appropriate to add new criteria, incorporate “lessons learned” as more escorting experience is gained in the industry, or to include alternative methodologies for analyzing the criteria.

1.6 This guide addresses physical control of the disabled ship with the assistance of the escort vessel(s). Other possible functions, such as firefighting, piloting, or navigational redundancy, are outside the scope of this guide. Also, this guide was developed for application to oceangoing ships in coastal waterways; it is not suitable for application to barge strings in riverine environments.

2. Referenced Documents
2.1 Code of Federal Regulations Document:
33 CFR Part 168—Escort Vessels for Certain Tankers, Final Rule
2.2 IMO Resolutions:
IMO Resolution A.601(15)—Provision and Display of Maneuvering Information on Board Ships
IMO Resolution A.751(18)—Interim Standards for Ship Maneuverability
2.3 Marine Safety Committee Circulars:
MSC Circular 389/Interim Guidelines for Estimating Maneuvering Performance in Ship Design
MSC Circular 644/Explanatory Notes to the Interim Standards for Ship Maneuverability

3. Terminology
3.1 For purposes of clarity within this guide, the vessel being escorted is referred to as the “ship” or “disabled ship.” The vessel accompanying the ship as its escort is referred to as the “escort vessel.”

3.2 The escorting measures addressed in this guide are based on performance.

---

2 Available from the International Maritime Organization, 4 Albert Embankment, London, SE1 7SR U.K.
3.2.1 The term “performance measure” refers to performance capabilities that must be possessed by the escort vessel(s) in controlling the disabled ship within a particular waterway. This requires a holistic analysis of the combined maneuvering dynamics of the escort vessel(s) and ship within the waterway in ambient weather and sea conditions. Performance-based requirements involve extensive preplanning and analyses, but offer greater assurance that the escort vessel(s) actually will be effective. The methodologies and processes presented in this guide can be used in determining the performance envelope of an escort vessel at different transit speeds and under a range of weather and sea conditions.

3.3 The terms “conventional propulsion” and “omni-directional propulsion” refer to propulsion systems of the escort vessel.

3.3.1 Conventional Propulsion System—The propulsive thrust is fixed in a fore/aft direction.

3.3.2 Omni-Directional Propulsion System—The propulsive thrust is steerable in any direction (360°) around the hull. Examples are the azimuthing Z-drive screw propeller system and the vertical axis cycloidal system.

3.4 The terms “direct mode” and “indirect mode” refer to two towing modes for exerting control forces on a disabled ship via towline from the escort vessel.

3.4.1 Direct Mode—The towline force is derived directly from the escort vessel’s propulsion system. In general, the towline orientation is over the bow or over the stern of the escort vessel, and only the propulsive thrust vector parallel to the towline axis is effective on the disabled ship.

3.4.2 Indirect Mode—The towline force is derived from the escort vessel’s hull drag as it is pulled along behind the disabled ship (similar to a drag chute). High-performance escort vessels should have sufficient stability so that they can turn approximately sideways to the towline without capsizing.
3.6.9 maneuvering coefficients, \( n \)—a set of numerical coefficients the are used in polynomial representations of the forces acting on a ship in terms of the instantaneous state of the ship.

3.6.10 oppose maneuver, \( n \)—an escort vessel maneuver in which the assisting escort vessel(s) apply maximum steering force to a disabled ship to turn the ship against its rudder. In this maneuver, the objective is to return the ship to its original heading by opposing the rudder forces.

3.6.11 propulsion failure, \( n \)—the ship is unable to propel or actively stop itself.

3.6.12 response times, \( n \)—the sequence of time delays following a disabling failure on a transiting ship before the escort vessel(s) can apply corrective forces.

3.6.13 rescue tow, \( n \)—a maneuver in which the escort vessel makes up lines and pulls the disabled ship; undertaken after all forward way has come off the disabled ship.

3.6.14 retard maneuver, \( n \)—an escort vessel maneuver in which the assisting escort vessel(s) apply maximum braking force to a disabled ship. In this maneuver, the objective is to take speed off the ship as quickly as possible by pulling astern. The control of a ship’s heading is not an objective. Also referred to as arrest.

3.6.15 rudder failure, \( n \)—the ship’s rudder is locked at some angle or it is swinging uncontrollably.

3.6.16 ship track/course, \( n \)—the path covered by the ship’s center of gravity during a voyage, a waterway transit, or a maneuver.

3.6.17 tactical diameter, \( n \)—the distance, perpendicular to the original course direction, between the ship’s center of gravity at the start and at the end of a 180° heading change.

3.6.18 zigzag maneuver, \( n \)—a test used to measure the effectiveness of the rudder to initiate and check course changes. The maneuver is described in MSC Circular 644, Section 2.2.

3.7 Evaluation and Selection Variables:

3.7.1 transit speeds, \( n \)—the speed of the escorted ship measured through the water. The transit speed takes into account tidal and wind-driven currents. Transit speed is not over ground (SOG) as measured by Global Positioning System (GPS), Loran, or radar.

3.7.2 bollard pull, \( n \)—the maximum sustainable force that the escort vessel is able to develop while pulling on a towline attached to a stationary object. The forward and astern bollard pull are individually specified.

3.7.3 dynamic pull (at a particular speed), \( n \)—the maximum sustainable force that the escort vessel is able to develop while moving through the water at a particular speed.

3.7.4 transfer, \( n \)—the distance perpendicular to the original track that a ship’s center of gravity travels in a 90° change in heading.

3.7.5 advance, \( n \)—the distance parallel to the original track that a ship’s center of gravity travels in a 90° change of heading.

3.7.6 performance limits, \( n \)—limits of performance measures such that under all circumstances, the use of vessels, equipment, or crew shall not place the life and safety of
individuals in jeopardy. No applicable federal or state regulations should be exceeded in determining escort vessel performance capabilities and limits.

4. Significance and Use

4.1 This guide presents some methodologies to predict the forces required to bring a disabled ship under control within the available limits of the waterway, taking into account local influences of wind and sea conditions. Presented are methodologies to determine the control forces that an escort vessel can reasonably be expected to impose on a disabled ship, taking into account the design of the ship, transit speed, winds, currents, and sea conditions. In some instances, this guide presents formulae that can be used directly; in other instances, in which the interaction of various factors is more complicated, it presents analytic processes that can be used in developing computer simulations.

4.2 Unlike the more traditional work of berthing assistance in sheltered harbors or pulling a “dead ship” on the end of a long towline, the escorting mission assumes that the disabled ship will be at transit speed at the time of failure, and that it could be in exposed waters subject to wind, current, and sea conditions.

4.3 The navigational constraints of the channel or waterway might restrict the available maneuvering area within which the disabled ship must be brought under control before it runs aground or collides with fixed objects in the waterway (see allision).

4.4 The escort mission requires escort vessel(s) that are capable of responding in timely fashion and that can safely apply substantial control forces to the disabled ship. This entails evaluation of the escort vessel’s horsepower, steering and retarding forces at various speeds, maneuverability, stability, and outfitting (towing gear, fendering, and so forth). This guide can be used in developing escort plans for selecting suitable escort vessel(s) for specific ships in specific waterways.

4.5 The methodologies and processes outlined in this guide are for performance-based analyses of escort scenarios. This means that the acceptability of a vessel (or combination of vessels) for escorting is based upon the ability to control the disabled ship in accordance with specified performance criteria. This guide addresses four selected performance measures:

- **Towing**—the ability to tow the disabled ship under specified parameters,
- **Stopping**—the ability to stop the disabled ship within specified parameters,
- **Turning**—the ability to turn the disabled ship within specified parameters, and
- **Holding steady**—the ability to hold the disabled ship on a steady course under specified parameters.

4.6 The “specified parameters” are additional details that must be factored into the performance analysis. These parameters might be specified by a regulatory agency imposing the escort requirement, by a study group evaluating the feasibility of escorting in a particular waterway, or by the ship or escort vessel operators themselves to define the performance envelope of their vessels. Some examples of these parameters are:

- **4.6.1 A ship transit speed (at the moment of failure);**
- **4.6.2 The failure scenario (rudder failure alone, or simultaneous rudder propulsion failure, degree of failure, and so forth);**
- **4.6.3 Navigational constraint within which the disabled ship must be brought under control (such as allowable advance and transfer, cross-track error, and so forth);**
- **4.6.4 Wind, current, and sea conditions; and**
- **4.6.5 Time delays, failure recognition, decision making, escort vessel notification, escort vessel positioning, achieving full power, and so forth.**

4.7 The anticipated users of this guide are:

- **4.7.1 Ship owners/operators who are required to select escort vessel(s) that meet the performance measures addressed by this guide.**
- **4.7.2 Escort vessel designers/operators who need to evaluate the performance capabilities of their vessels with respect to the measures addressed by this guide.**
- **4.7.3 Regulatory agencies that have imposed the performance measures in this guide in a particular waterway to develop suitable escort vessel matrices for various sized ships in the waterway.**
- **4.7.4 Enforcement agencies can use this guide to confirm/verify compliance with the performance measures (that is, that suitable escort vessel(s) are being selected).**
- **4.7.5 Study groups can use this guide to explore the feasibility and effectiveness of escorting as a means of mitigating risk on a particular waterway.**

4.8 This guide does not address the use of escort vessels with barge fleets or barge tows. However, some sections of this guide would be useful if an evaluation of escort vessels with barge shipments were undertaken. Paragraphs 5.4 and 5.5, and all of Section 6 would apply in this type of analysis.

4.9 The methodologies and processes presented in this guide will yield valid solutions to the performance measures. This means that the selected escort vessel(s) can reasonably be expected to control the disabled ship within the specified parameters. However, users are reminded that other circumstances surrounding the disabling incident may still preclude the escorts from safely responding (such as fire).

4.10 The methodologies in this guide are not necessarily the only ones that can be used to find solutions for the performance measures. There may be other analytic approaches that also will yield valid results. It is hoped that as these alternative methods are developed, they will be incorporated into this guide.

5. Data Requirements for Analysis

5.1 This section describes the data required for an escort vessel evaluation and selection analysis. This analysis is part of the development of an escort plan. The data recommended for inclusion in an escort plan document are presented in Section 8.

5.2 The data required for this analysis must be either an accurate evaluation of ship and escort vessel characteristics or must be based on conservative assumptions regarding those characteristics.

5.3 Ship Data:

- **5.3.1 It is recommended that, as a minimum, the ship information contained on the IMO A.601(15) defined pilot card**
and wheelhouse poster be collected for use in developing and verifying an escort vessel analysis. Examples of the pilot card and wheelhouse poster are shown in Figs. 2-5. The completed forms can be made part of an escort plan.

5.3.2 In addition, the following ship-specific characteristics can be used in the development of an escort plan and can be used in the validation of ship-maneuvering simulation computer models:

5.3.2.1 Unpropelled advance and transfer distances starting from an engine stop order with rudder amidships at the proposed transit speed until a speed of 1 knot is achieved in calm conditions at level trim in deep water.

5.3.2.2 Crash stop (full engine astern) advance and transfer distances at a speed of 1 knot with port and starboard locked rudder starting from the proposed transit speed in calm conditions at level trim in deep water.

5.3.2.3 Dead ship tow behavior and tow force requirements for a range of wind speeds characteristic of the escort area, including associated wave heights and the effects of vessel trim on towing behavior.

5.3.2.4 Data from full-scale ship-escort vessel trials, if conducted.

5.4 Escort Vessel Data:

5.4.1 It is recommended that, as a minimum, the escort vessel information shown in Fig. 6 be obtained.

5.4.2 In addition, the additional information shown in Fig. 7 can be used in the development of an escort plan.

**FIG. 2 Pilot Card**
5.4.3 Alternatively, data from scale model testing or instrumented full-scale trials can be used in the development of an escort plan.

5.5 Waterway Data:

5.5.1 Transit Routes and Escort Zones—Transit route(s) through the escort area must be identified. For routes that pass through distinctly different regions, it may be beneficial to divide the escort area into separate zones based on the environment and the severity of the constraints. This procedure will separate a zone with severe constraints from one that is less restrictive. Different escort vessels can be used in the different zones to satisfy the requirements of this guide.

5.5.2 Navigational Constraints—The geography of the escort area should be evaluated to determine its navigational limits. It is within these constraints that a disabled ship must be stopped or controlled if a grounding is to be prevented. Such limits might be prescribed by a minimum under-keel clearance, a particular depth contour, or a safety distance from a point hazard.

5.5.3 Environmental Conditions—The climatology of the escort area, including wind speeds, wind directions, wave heights, wave periods, wave directions, current speeds, and current directions should be assembled. If there are significant seasonal variations in the climatological conditions and if seasonally varying escort plans are to be prepared, then the climatological data for each season should be assembled.

5.5.4 Particular Hazards—A list of points of particular hazard along the transit route should be compiled.

6. Determination of Escort Vessel Capability

6.1 Two different approaches to escort vessel performance measures are presented. Paragraph 6.2 discusses selected performance measures. Paragraph 6.3 discusses operational performance measures. Operational performance measures differ from selected performance measures in both definition and methodology for determination of adequacy.

6.2 Selected Performance Measures:

6.2.1 Selected performance measures can be thought of as the ship demand for escort vessel capability. These measures can be chosen by regulatory bodies at either the state or national level, or they can be chosen by vessel operators as a means of setting minimum performance standards for their own evaluation and selection of escort vessel(s). These measures can be specified so as to be waterway and weather independent. They would not require consideration of such operational issues as time delays for the application of escort vessel force and procedures for applying those forces.

FIG. 5 Man Overboard Rescue Maneuver
6.2.2 Example performance measures are presented in Appendix X1.

6.3 Operational Performance Measures:

6.3.1 Operational performance measures are ship, waterway, and season specific. An example of this type of performance measure is contained in 33 CFR 168.50 Part (a). It reads, in part: "...at all times during the escort transit each tanker to which this part applies: ...(2) Must have the escort vessels positioned relative to the tanker such that timely response to a propulsion or steering failure can be effected. (3) Must not exceed a speed beyond which the escort vessels can reasonably be expected to safely bring the tanker under control within the navigational limits of the waterway, taking into consideration ambient sea and weather conditions, surrounding vessel traffic, hazards, and other factors that may reduce the available sea room." An operational analysis needs to consider transit speed, time delays, sea and weather conditions, navigational constraints, failure modes, type of assistance used, ship fitting, and other factors.

6.3.2 The adequacy of the escort under this section can be demonstrated through computer simulations, model-scale or full-scale trials, or a combination of both.

6.3.3 Failure Modes—Failure modes for an operational analysis are to be defined. Possible failure modes include propulsion failure, steering failure, or steering failure without the use of ship propulsion. The escort requirements differ significantly, depending on the failure scenario.

6.3.4 Time Delays—Time delays for an operational analysis are to be defined. Actual time delays can vary significantly as a result of differences in human performance, weather conditions, nature of casualty, ship speed, escort vessel type, escort position, escort mode, emergency assist procedures, and equipment. The time delay chain of events should include each of the following, if applicable.

6.3.4.1 Time delay for failure recognition aboard the transiting ship (consideration can be given to on-board failure alarm systems),
6.3.4.2 Time delay to consider options and cures and notify escort vessel(s).
6.3.4.3 Time required to maneuver escort vessel(s) from its escort position to the ship.
6.3.4.4 Time required to connect any lines, and
6.3.4.5 Time required to stream lines and develop tension.
6.3.5 The possibility that an emergency assist might be required under adverse conditions, such as storms, darkness, times of poor visibility, conditions with ice on the decks, or difficult communications caused by winds and darkness, is to be considered.
6.3.6 Estimates should be based on experience, full-scale trials, commentary from experienced masters, and other reliable available data.
6.3.7 Type of Assistance:
6.3.7.1 An escort vessel must be capable of providing assistance in towing, stopping, and steering. The way in which this assistance is provided will depend on the nature of the ship’s casualty, its speed, navigational constraints, escort vessel type, escort position, and escort mode (whether tethered or untethered).
6.3.7.2 The towline forces for steering and braking assist can be substantially higher than the loads that the bitts and chocks of many existing ships have been designed to accommodate. The braking and steering assist forces above the safe limits of the ship’s fittings should not be considered in an operational analysis.
6.3.7.3 The capability limits of escort vessel fittings should be evaluated. Assist forces above the safe limits of the escort vessel fittings should not be considered in an operational analysis.
6.3.7.4 The use of the disabled ship’s astern thrust and the deployment of its anchors to complement the action of the escort vessel(s) or other actions should be considered.
6.3.8 Navigational Constraints:
6.3.8.1 A quantitative definition of the navigational constraints for each escort zone in terms of an allowable reach and an allowable transfer must be determined. The analysis is to include distances to point constraints such as bridges, rocks, and islands, as well as to bottom contours. In evaluating the navigational constraint, consideration can be made between grounding on hard bottom, which may potentially open the hull, and on soft bottom, such as mud, which may not.

6.3.8.2 It is not intended that the escort analysis or escort plan define the transit route that ships must take in a particular waterway. It is recognized that tracklines chosen during an actual transit may differ from those used in the preparation of the escort plan. However, the escort plan should be based on the average or most likely route that the ship will take in the waterway. Thus, allowable reach and transfer distances can be based on the average or most likely transit route.

6.3.8.3 The offtrack distances from a disabling failure scenario, including the effects of escort vessel assistance, are to be compared with these allowable distances to determine the adequacy of escort vessel selection. The offtrack distances can be obtained from full-scale trials, model-scale testing, or computer simulations.

6.3.8.4 There are several methods of determining the numerical values of the available reach and transfer distances. The simplest is to choose the absolute minimums as used from a trackline chosen for each ship’s purposes. Using this definition, the reach constraint would be the shortest straight-ahead distance from a turn in the transit route to the constraint directly ahead. The minimum transfer distance would be the shortest perpendicular distance to constraints on either side. However, if this approach is adopted, the escort requirement would be based on a single-point exposure to the worst case hazard, which may be too restrictive in relation to the entire transit route.

6.3.8.5 An alternative approach is to define the reach and transfer constraints as a statistical measure of the exposure of the vessel to potential grounding/allision situations. The statistical measure could be the average distance ahead and abeam measured throughout the entire transit in the escort zone of interest. Percentile measures of reach and transfer distances can also be determined. For example, the 95th or 98th percentile levels can be used to define the navigational constraint. The procedure for the calculation of statistically defined constraints begins by measuring the reach and transfer distances from the normal ship track to a constraint. To do this, the transit is divided into evenly spaced segments, and the ahead and abeam distances measured. A histogram of the measurements showing the frequency distribution of reach and transfer is then constructed (Fig. 8). Cumulative frequency distributions are developed and used to determine the percentile reach and transfer for any particular transit. An example calculation is shown in Figs. 9 and 10.

6.3.8.6 Other reasonable methods of determining available reach and transfer distances may be developed.

6.3.9 Environmental Conditions—The behavior of a disabled ship and the capability of an escort system are influenced by the environmental conditions. The environmental factors to be considered include wind speeds, direction and duration, wave heights, periods and directions, current velocities, and direction. Seasonal variations in climatological conditions should be considered in escort operations analysis and escort vessel selection.

6.4 Stability of Escort Vessels:

6.4.1 Some modes of escorting may result in an escort vessel being subjected to forces, both static and dynamic, that cause heeling moments in excess of those for which the escort vessel was originally designed.

6.4.2 Conventional stability analysis techniques consider the effects of heeling moments only in a static condition. The impact of vessel speed and the resulting hydrodynamic forces acting on the vessel are not considered.

6.4.3 Escort vessels with omni-directional propulsion systems deliberately can be placed abeam to the direction of the tow line to achieve high retarding forces. Such attitudes can result in high heeling angles at higher speeds and, thus, a potentially sudden incidence of deck edge submergence.
6.4.4 The stability analysis of escort vessels must consider all potential attitudes of the escort vessel to the direction of line pull, the maximum line pull, and the resultant combination of heel and trim on the escort vessel.

6.4.5 For all escort vessels, a limiting heel angle must be established. This limit might be the geometrical submergence of the main deck, including the loss of freeboard as a result of waves.

6.4.6 The stability analysis must include the effects of fenders, skegs, nozzles, rudders, and any other appendages on both the reserve buoyancy and the lateral resistance of the escort vessel.

6.4.7 The stability analysis must include the contribution to heel and trim of the propulsion system in conjunction with maximum line forces.

6.4.8 The stability analysis must include an evaluation of the reaction of the escort vessel to an instantaneous release of the line forces and the propulsive forces.

6.5 Procedures for Determination of Escort Vessel Capabilities:

6.5.1 Full-Scale Trials:
6.5.1.1 Full-scale ship-escort vessel trials, wherever they can be properly designed and safely executed, may be used to verify the adequacy of escort vessel(s). These trials should be carefully planned in conjunction with ship owners and escort vessel operators to ensure proper evaluation of escort vessel(s).

The differences between the environmental conditions prevailing at the time of the test and the postulated environmental conditions during the actual transit should be accounted for in the analysis.

6.5.1.2 Full-scale ship-escort vessel makeup trials can provide examples of the time taken by an escort vessel to approach a ship and begin to render effective assistance. However, the trials may take place in conditions different from emergency conditions and when the crew is fully prepared for the test. Thus, time delays obtained in these tests will, in most cases, underestimate the time required in a true emergency.

6.5.1.3 The ship’s position during the course of the trials is to be continuously recorded. Observers should be stationed on the vessels to monitor the precise sequence of events aboard the ship and the actions taken by the escort vessel(s). The water depth, the ship’s loaded condition, the load condition of the escort vessel, and the environmental conditions prevailing at the time of the trials are to be noted.

6.5.1.4 At no point in the course of the trials should the safety of the vessels and their crew be compromised.

6.5.1.5 At the conclusion of the trials, the results are to be analyzed and the ship tracks plotted. Corrections for any currents, wind loads, ship and escort vessel operating condition, and the GPS antenna location on the ship are to be incorporated, if applicable.

6.5.2 Ship Model for Computer Simulation:
6.5.2.1 As an alternative to full-scale trials, a validated ship-maneuvering simulation program can be used to verify the adequacy of escort vessel(s).

6.5.2.2 The coefficients of the underlying mathematical model of ship maneuvering may be obtained from an appropriate database established by properly conducted physical model tests. The coefficient set shall be suitable for the type of ship and the waterway bathymetry being modeled. Restricted water effects, such as bank suction and shallow water effects on maneuvering, shall be considered. Effects of ship-ship interaction on maneuvering shall be considered where appropriate.

6.5.3 Escort Vessel Model for Computer Simulation:

6.5.3.1 The performance of an escort vessel in an emergency maneuver depends on its ability to apply corrective forces to the disabled ship either through a line or through direct contact with the ship’s hull. The forces may be applied while the disabled ship is still moving at speeds close to its transit speed, except where sea room is available to allow the disabled ship to slow without escort vessel intervention. Three distinct assist modes are to be evaluated. They are: stopping (also called retarding or arresting), steering, and towing. The assist forces in these modes should be properly evaluated and applied to the ship model as external forces.

6.5.3.2 Conventionally propelled escort vessels apply braking force by backing down on a head line while being dragged through the water by the disabled ship. The braking capability and clutch-in speed of a conventional escort vessel can be calculated using fourth quadrant open water propeller curves for the installed propellers, including the hull-propeller interaction effects, and the drag of the hull. For conventionally propelled escort vessels, the braking force may be assumed to be constant up to the clutch-in speed and equal to that measured in reverse bollard pull trials.

6.5.3.3 The braking force of a vertical axis cycloidal escort vessel (in direct and indirect modes) and the braking force of an azimuthing propelled escort vessel (in reverse, transverse, or indirect modes) can be calculated from open water propeller curves for the installed propellers, including the hull-propeller and propeller-propeller interaction effects, and the lift and drag of the hull at its equilibrium attitude to the flow.

6.5.3.4 Alternatively, the braking force as a function of advance speed can be determined from scale-model testing or instrumented full-scale trials.

6.5.3.5 The emergency assist steering capability of the escort vessels can be quantified by a pair of speed-dependent vector force functions, a maximum steering force together with an associated pushing or braking force. The hydrodynamics of the underwater hull with any skegs, rudders, and appendages, the propeller characteristics and stability, including freeboard and metacentric height, should be considered in the evaluation of these vector force functions. The assumed position of the escort vessel at the bow or stern, or when pushing on the side or transom, or when pulling on a line, is to be properly modeled. When the escort vessel is pushing on the transom or

FIG. 10 Example Statistical Transfer Distances
the side of the disabled ship or pulling on a headline, the steering force is accompanied by a longitudinal force which affects the speed of the disabled ship. Likewise, when steering by pulling on a line from the stern of the disabled ship, the steering force is accompanied by a braking force which can affect the speed of the ship.

6.5.3.6 For all escort vessel types, a heel angle limit should be established. This limit can be the geometrical submergence of the main deck edge including the loss of freeboard as a result of waves. Even though it may be possible to submerge a portion of the main deck and produce somewhat larger steering forces, the stability of the escort vessel decreases rapidly.

6.5.3.7 The emergency assist steering capability of the escort vessel can be calculated by solving the equilibrium free body problems for a hull in a free stream. The solution corresponds to a quasi-steady state condition in which the horizontal-plane forces and moments are in balance. The dynamic fluctuations in the forcing functions can be assumed to be negligible with respect to the time rate of change of ship momentum, and small with respect to the average force capability of the escort vessel. The analysis should include the hydrodynamic forces on the escort vessel hull, skeg, and other appendages and fenders; the lift and drag forces acting on the rudders (if present); and the thrust of the propellers. The analysis should include flow modifications, such as the flow straightening and wake effects of the hull on the flow entering the propellers, and modifications to the direction and magnitude of the velocity field acting on the rudders (if present) as a result of the propeller slipstream. In addition to the hydrodynamic forces on the underwater hull, the equilibrium is affected by all lines and escort vessel-ship contact. The components of a complete quasi-steady state analysis are summarized in Appendix X2. Effects of escort vessel motions on freeboard can be ignored. These are time-dependent dynamic processes and can be assumed not to affect significantly the quasi-steady state solution.

6.5.3.8 Alternatively, the emergency assist steering force as a function of advance speed can be determined from scale-model testing or instrumented full-scale trials.

6.5.3.9 Towing capability can be determined by the thrust and torque characteristics of the propeller and the resistance of the escort vessel, towed vessel, and towline at speed. The calculation should use an accurate model of the escort vessel’s propulsion system. The solution of thrust, torque, RPM, and required power should be checked for propeller cavitation, RPM limitations, and engine capacity. The towing capability predicted in calm water should be modified for sea conditions by reducing the RPM of the engines and adding steady wave forces and wind loads to the escort vessel hull.

6.5.3.10 Capability Reductions Because of Vessel Condition—Towing performance is reduced as the engines, shafting, and propellers deviate from design specifications. Accountability should be made for significant changes in capability caused by any change in escort vessel condition. The performance of a selected escort vessel can change as a result of the degradation of equipment or stability characteristics over time. The capability of the selected escort vessel(s) should be reassessed periodically to ensure the performance is adequate to meet the needs of the escort plan.

6.6 Escort Vessel Equipment:

6.6.1 The fittings and equipment installed in an escort vessel must be capable of, and suitable for, the safe transmission of forces and loads between the escort vessel and the designated ship. Both the equipment and the manner in which it is connected to the structure of the escort vessel must be designed in recognition of the maximum loads anticipated during emergency maneuvers.

6.6.2 Towline Winch—Winches designed for installation on board escort vessels shall be designed and constructed in accordance with the following specifications:

6.6.2.1 The winch foundation, drum, and ancillary structures shall be designed to accept the maximum anticipated dynamic and static loads with appropriate factors of safety.

6.6.2.2 Winch performance shall be commensurate with the operator’s requirements for safe operations. Performance criteria of light line speed, static line pull, and brake capacity of the winch should be considered when evaluating the escort vessel’s suitability. Other tow winch features that should be considered are a fail-safe and properly located abort mechanism, load tension devices, and a method to spool the towline to prevent burying under severe tension.

6.6.3 Towlines:

6.6.3.1 The towline between the escort vessel and ship is critical to any successful escort maneuver, but should be designed as the weak link in the system. The towline should fail before any mechanical or structural component on the escort vessel. If the strength of the towing connection on a designated ship is unknown or suspect, the escort vessel operator may consider operational restrictions that would reduce the potential for high line loads.

6.6.3.2 Towlines for escort service should be sized to the mission and capabilities of the escort vessel, with consideration of the appropriate safety factor of the type of line used.

6.6.3.3 Towlines for escort duty must be routinely inspected for proper condition.

6.6.4 Towline Connectors—Instead of a line winch and towline stored aboard and controlled by the escort vessel, the connection between the escort vessel and ship may be made by using a towline stored aboard the designated ship. In this case, the escort vessel must be equipped with a device capable of the following:

6.6.4.1 Rapidly and safely securing the line to the escort vessel,

6.6.4.2 Rapidly and safely disconnecting the line from the escort vessel, and

6.6.4.3 Sustaining the highest anticipated loads experienced during the escort maneuvers.

6.6.5 Ground Tackle—Escort vessels should be equipped with ground tackle (anchors, cables, and so forth) in compliance with classification society requirements for ocean service.

6.6.6 Fendering:

6.6.6.1 Escort vessels shall be fully fendered to preclude damage in the event of contact between the escort vessel and the designated ship.
6.6.6.2 Fender type and geometry shall be arranged to provide a resilient contact zone between the escort vessel and ship, such that when the maximum static bollard pull of the escort vessel is applied, the structural limits of the ship’s side or stern are not exceeded, and the fender system is not stressed beyond its design limits.

6.6.7 A line-throwing apparatus is required to facilitate rapid connection between the escort vessel and the ship.

7. Methodology for Escort Vessel Selection

7.1 The methodologies presented in this section provide the user with three alternatives for analyzing an escort situation and can be used as guidance in the selection of an escort vessel. The different approaches are: (1) a ship-specific analysis using computer simulation of specific escort vessel(s) in a matrix of operating conditions; (2) a parametric study of the trends in the results of escort vessel-assisted maneuvers using a number of ships, escort vessel(s), and operating conditions; and (3) a demand versus capability study.

7.2 Other methodologies may be developed for escort vessel selection, but must be validated with literature citations, scale-model testing, or full-scale testing.

7.3 Simulation Matrices:

7.3.1 The use of a matrix of scenarios to identify escort requirements is based on an analysis of individual or representative ships matched with specific escort vessel(s). This method requires using ship-specific and escort vessel-specific information.

7.3.2 A matrix of simulation cases is to be defined so that acceptable escort solutions can be identified for each escort area and transit condition. The matrix should include appropriate combinations covering all relevant geographic regions, climatic conditions, navigational conditions, operating speeds, failure modes, escort deployments, time delays, and types of assistance.

7.3.3 A computer simulation of the escort vessel acting on the disabled ship should be carried out for each combination in the matrix. The resulting ship trackline should be plotted and then compared with the navigational constraints of the waterway. Based on this process, acceptable escorts are identified for all applicable geographic regions, climatic conditions, navigational conditions, and transit speeds.

7.3.4 Computer simulation of disabled ship maneuvers with escort vessel assist requires a validated computer model. This can be accomplished using the ship and escort vessel information discussed in 5.1, 5.2, and Section 6. Additional validation can come from full-scale trials.

7.4 Parametric Studies:

7.4.1 A parametric study is an extension of the matrix of simulation cases presented in 7.3. However, unlike the matrix of cases described in 7.3, which evaluated specific climatic conditions and transit speeds, this approach uses a matrix of scenarios based on parametric variations in climatic conditions, operating speeds, and time delays. Each scenario in the matrix is analyzed using a particular ship and escort vessel.

7.4.2 The results of the parametric study can be presented in a graphical form by plotting a measure representing the outcome of the emergency assist (transfer distance) as a function of any of the underlying parameters, while holding the remaining parameters fixed. For example, a plot of the transfer distance as a function of the initial speed will clearly demonstrate the change in the escort vessel’s ability to control the ship as transit speed changes. Similarly, a plot of the transfer distance as a function of wind speed or current speed will show the change in the ability of the escort vessel to control a disabled ship in different climatic conditions. In this example, comparing the transfer results with the navigational limits of the waterway will enable the selection of a transit speed or an environmentally imposed operational limit.

7.4.3 Computer simulation of disabled ship maneuvers with escort vessel assist requires a validated computer model. This can be accomplished using the ship and escort vessel information discussed in 5.1, 5.2, and Section 6. Additional validation can come from full-scale trials.

7.5 Demand Versus Capability Formulation:

7.5.1 The approach is advantageous when a diverse range of escorted ships and escort vessels are to be considered. It can be used to select a suitable escort system for a given ship at a prescribed displacement and speed, transiting a particular escort area. The ship’s “demand” for assist forces is separated from the “capability” of the escort vessel and must not exceed the demand to have an acceptable escort system.

7.5.2 The demands of the ship requiring escort shall be quantified as a function of the displacement, speed, time delays, and the prevailing environment. The “demand” measures generally take on scalar values of force or distance. They should be specific to the failure mode and the escort area. They are to be independent of escort vessel parameters.

7.5.3 The capabilities of a vessel providing escort should be established as a function of the speed and the prevailing environment. They should be independent of ship parameters. The capability measures must have the same measurement units as the demand.

7.5.4 Once the demands and capabilities are established, they should be clearly tabulated. The governing demand can be taken as the maximum demand across all possible failure modes. An escort vessel or escort vessel combinations with a total capability sufficient to meet or exceed the governing demand qualify as acceptable escorts. Alternative escort choices for any given ship at a prescribed displacement and transit speed in any escort area should then be easily identifiable from the tables.

7.5.5 Because of the simplifying assumptions inherent in a demand versus capability formulation, the demand and capability determination of escort vessel selection should be double-checked. This should be done by demonstrating that the selected escort vessel(s) capabilities meet or exceed the demand of a disabled ship, and that they are capable of rendering timely assistance to the disabled ship and bringing it under control within the navigational limits of the waterway, taking into consideration ambient sea and weather conditions, surrounding vessel traffic, hazards, and other factors that may reduce the available sea room. The validation should be carried out through full-scale trials or computer simulations and should cover the full range of ship, escort vessel, and environmental parameters.
8. Preparation of An Escort Plan

8.1 Components of an Escort Plan—This section provides recommendations for developing an escort plan. The plan may be ship- or ship class-specific. It should provide clear and precise instructions regarding the escorted segment of the voyage. Forms are to be developed and included in the plan for presenting the applicable voyage, ship- and escort vessel-specific information. Flowcharts may be developed for the various activities to be performed.

8.2 Information and Assumptions:

8.2.1 It is recommended that able ship-maneuvering characteristics be compiled in the form of the maneuvering booklet recommended in IMO Resolution A.601(15). MSC/Circular 389 may be consulted for guidance on estimating maneuvering performance. In addition, escort-specific information, including the current condition of the ship with regard to its loading, propulsion and maneuvering equipment, and so forth, should be available in the form of the pilot card recommended in IMO Resolution A. 601(15).

8.2.2 The plan should include all additional information that is useful for understanding the ship’s behavior and how it affects emergency assist requirements. If this information is not available, the escort plan should indicate that it is not available. Data from full-scale ship-escort vessel trials, if available, are to be assembled and included in the escort plan.

8.2.3 Any assumptions used in the selection of the escort vessel(s) should be documented. These include time delays, failure modes, environmental conditions, and emergency assist maneuvers.

8.2.4 Particular Hazards—The escort plan should include a list of points of particular hazard along the escort transit or shall contain a reference to the relevant published compilation of the points of particular hazard, such as the Coast Pilot.

8.2.5 All Coast Guard, VTS, and marine traffic control contacts, radio frequencies, and phone numbers for the escort area should be listed in the escort plan.

8.2.6 The climatology of the escort operating area, including winds, currents, and sea conditions, should be assembled and included in the escort plan. If there are significant seasonal variations in the climatological conditions and if seasonally varying escort plans are to be prepared, then the climatological data for each season should be assembled and included in the escort plan.

8.3 Equipment and Deployment:

8.3.1 A stand-alone diagram or flowchart can be included that describes the equipment involved and the methods employed in making an emergency towline connection (if one is required to be made in accordance with the escort plan).

8.3.2 The plan should include the location and load capacities of the bitts, chocks, and hard points to be used in an emergency assist.

8.4 Escort Selection:

8.4.1 The escort plan should indicate available escort vessel or vessel combinations capable of providing escort.

8.4.2 The plan should specify where to position the escort vessel(s). In this section, consideration should be given to the safety of the escort vessel(s) and to the time it takes for the escort vessel(s) to provide the emergency assistance.

8.4.3 The plan should specify whether the escort vessel(s) will be tethered or not and, if tethered, whether it will be tethered during all or a portion of the transit.

8.4.4 If any portion of the escort transit is untethered, then the plan should define if and how the escort vessel(s) will tether during an emergency.

8.5 Escort Transit Speed:

8.5.1 The speed for a specific transit should be determined in compliance with 33 CFR 168. This speed might depend on the anticipated environmental conditions (winds, currents, and sea conditions) and the capability of the escort vessel(s).

8.5.2 The intended speed for each portion of the transit should be clearly indicated on the escort plan.

8.5.3 The plan should contain a notice that the speeds written are “through the water” speeds and that they differ from speeds “over ground” by the amount of the current.

8.6 The plan should contain documentation of the results of all proposed emergency assist maneuvers. The predicted outcome of the emergency assist maneuvers should be shown on the escort plan at key points along the route.

8.7 Alternatives to Primary Plan—The escort plan should clearly spell out alternative procedures for controlling the disabled ship if the primary plan cannot be executed.

8.8 Pre-Escort Planning and Conference—The plan should contain a procedure and a form (a sample format is given in Table 1) to use when conducting a pre-escort conference. The condition of the environment in which the escort is to take place, including winds, currents, and sea conditions and the consequences for escort vessel selection, should be discussed.

**APPENDIXES**

(Nonmandatory Information)

**X1. SELECTED PERFORMANCE MEASURES**

X1.1 Example performance measures in three assist modes are described herein. The demand and capability method described in 7.5 can be used to verify the compliance of an escort with these measures. In this method, the various parameters are first applied to the ship to determine the “demand.” The demand in these examples is some measure of performance, such as towing resistance, stopping ability, rudder force, or turning ability. This measure of performance is a function of the ship, its displacement, dimensions, proportions, propulsion system, and rudder system. The example assist modes are:

**X1.1.1 Ability to Tow the Disabled Ship at a Specified Speed in Calm Conditions and Holding It in a Steady Position Against a Specified Head Wind:**

X1.1.1.1 The ship demand in the first case is equal to the calm water resistance of the ship at the specified towing speed. The resistance of a ship may be estimated by the following:

\[ R = \frac{4\pi}{1000} C_{R} \rho \frac{V^{2/3}}{V^2} \]  

where:

- \( R \) = resistance,
- \( \rho \) = density of the water,
- \( V \) = displaced volume, and
- \( V \) = specified towing speed, in any consistent system of units.

\( C_{R} \) may be taken as 0.65 for a tanker or bulk carrier. Use any consistent set of units.
X1.1.2 The ship demand in the second case is equal to the wind load caused by the specified head wind. The load as a result of a head wind can be calculated as follows (loads are not included): 

$$F_w = K_p A_T V_w^2$$  \hspace{0.5cm} (X1.2) 

where:

- $V_w$ = the specified wind speed and 
- $A_T$ = the equivalent transverse projected area obtained by adding 30% of the projected transverse main hull area to the projected superstructure area. 
- $K_p$ may be taken to be 0.6. Use any consistent set of units. 

X1.1.3 The escort vessel(s) must have sufficient tow rope pull to match or exceed $R$, the calm water towing resistance at the specified speed, and their bollard pull must match or exceed the wind load, $F_w$. The wind drag resistance of the escort vessel is considered negligible and is ignored. 

X1.1.2 Ability to Hold the Ship on a Steady Course Against a Locked Rudder at a Specified Speed:

X1.1.2.1 The ship demand in this case is equal to the lift force generated by the rudder in a specified locked position with the propeller free wheeling at the RPM corresponding to the ambient flow. 

X1.1.2.2 In maneuvering simulation equations, the lift force generated by the rudder is represented by the following:

$$Y_{Rad} = \frac{1}{2} \rho L^2 U_R^2 \delta Y_{br}$$  \hspace{0.5cm} (X1.3) 

where:

- $Y_{Rad}$ = the lateral force, 
- $L$ = the length between perpendiculars, 
- $U_R$ = the assumed flow velocity at the rudder location, 
- $\delta$ = the rudder angle in radians, and 
- $Y_{br}$ = the nondimensional maneuvering coefficient used to represent the lateral rudder force as a function of the rudder angle and should depend on the effective rudder area. 

X1.1.2.3 The escort vessel(s) must be capable of generating counteracting steering forces at the specified speed to match or exceed this demand. The ship can then be held on a steady course, provided the steering force is applied at the transom. 

X1.1.2.4 This solution applies only to a single escort vessel applying steering forces at the transom. If multiple escort vessels are used, the moment arms of the rudder steering force and the counteracting steering forces must be determined and matched. 

X1.1.3 Ability to Turn the Ship 90°, Assuming a Free-Swinging Rudder in Deep Water and an Initial Specified Speed, Within a Specified Reach and Transfer Distance:

X1.1.3.1 When the escort vessel steering force is applied, the ship is assumed to be unpropelled, the rudder is assumed to be ineffective, and the escort vessel assist is to be treated as immediate and without time delay. Deep water is assumed. 

X1.1.3.2 The advance and transfer of the able ship may be obtained from the maneuvering card posted in the wheelhouse. Since the advance and transfer are nearly independent of speed, the wheelhouse information for slow speeds can be used in the evaluation at other speeds. 

X1.1.3.3 The behavior of the disabled ship with escort vessel assistance has to be assessed through ship-maneuvering simulations, model-scale, or full-scale trials. With the requirement to meet both the reach and transfer constraints simultaneously, the effect of the differences in steering modes between escort vessel types should be properly accounted for in the simulations. 

X1.1.4 The selected performance measure “demands” must be matched by the “capabilities” of escort vessel or escort vessel combinations. The ship operator can use these measures to choose any escort vessel combination that has sufficient capability to meet the demand. 

X1.1.5 Alternative validated methodologies for the calculation of the selected performance measures can be used. 

X2. COMPONENTS OF A STEADY-STATE ESCORT VESSEL PERFORMANCE ANALYSIS

X2.1 Lift, drag, and center of pressure of hull. 

X2.2 Lift, drag, and center of pressure of rudders, based on published flat plate and lifting surface coefficients, including effects of aspect ratio and edge effects (for conventional escort vessels). 

X2.3 Lift, drag, and center of pressure of skeg, including effects of aspect ratio. 

X2.4 Modification of flow into rudders resulting from hull shape (for conventional tugs). 

X2.5 Modification of flow into rudders resulting from momentum changes induced by the propellers (for conventional tugs). 

X2.6 Position of rudders with respect to propellers and local rudder angles (for conventional tugs). 

X2.7 Cross-flow effects as a result of tug orientation with respect to the free stream. 

X2.8 Effects of fendering on hydrodynamic performance of the hull. 

X2.9 Propeller performance, including engine, gearbox, and shafting characteristics, command RPM, and propeller geometry. 

X2.10 Effects of twin screw control. 

X2.11 Lift, drag, and center of pressure of propeller nozzles, if present. 

X2.12 Heeling moments caused by contact with ship, bow lines (if rigged), and transverse components of hull, skeg, rudder, nozzle, and propeller forces.
X2.13 Heeling moments caused by tow line tension (for tractor tugs working on a line).

X2.14 Freeboard and GM in the design condition, and the escort condition.

X2.15 Reduction in freeboard as a result of average wave amplitudes.

X2.16 Deck edge submergence.

X2.17 Friction between its fendering and the ship’s hull (for tugs working in contact with the disabled ship’s hull).

X2.18 Forces in lines.

X2.19 Position of tug on ship, either alongside, on the transom, or on a line.

X2.20 Use of additional thrusters.

X2.21 Actual condition of propellers and rudders, that is, effects of wear or damage.

X2.22 Reductions in available power because of vessel condition and maintenance.
Standard Practice for Selection of Wire and Cable Size in AWG or Metric Units

1. Scope

1.1 This practice is intended as a guide to shipbuilders, shipowners, and design agents for use in the selection of conductor size for single conductor or multiple conductor cable sizes either in American Wire Gauge (AWG) or metric designations for commercial ship design and construction.

1.2 The comparison chart of electrical conductor sizes shown in Table 1 presents a combined listing of international standard sizes of Class 2 stranded copper conductors in accordance with AWG (Specification B 8) English units or IEC (IEC 60228) metric units.

1.3 As a precautionary caveat, some conductor sizes listed in Table 1 may exceed minimal size requirements of the U.S. Coast Guard, the American Bureau of Shipping, and IEEE STD 45 for specific applications.

1.4 The values stated for ampacity and dc resistance are presented as maximum values and are provided for information only.

3. Significance and Use

3.1 The selection criteria is to be applied for uses of (1) new cable and (2) replacement cable.

3.2 For the selection of new cable or the selection of replacement cable, this practice defines the choice criteria for conductor selection for cables in AWG (ASTM) or metric (IEC) sizes.

4. Selection Criteria

4.1 When selecting cable for any application, AWG or metric sizing should be selected according to preferred sizes. The sizes of conductors that have been marked with an asterisk in Table 1 designate preferred sizes per Specification B 8 and IEC 60228. Those sizes not marked are given for reference, and it is recommended that their use be discouraged.

4.2 When selecting cable for any application, AWG or metric sizing should be selected with full consideration of the relationship of type of insulation and ampacity. Direct selection between AWG and metric sizes can be made only after a determination of the equivalence of insulation is made.

4.3 When selecting cable, the conductor size will be determined from analysis of required ampacity, voltage drop considerations, type of cable insulation, and planned installation. Recommended practices for selection and installation of cable systems are detailed in IEEE STD 45 and IEC 60092-350.

4.4 For the selection of cable sizes for new applications, conductor size that satisfies ampacity requirements, voltage drop factors, and the adequacy for application in the available cable space must also be considered.

4.5 For the selection of cable sizes for replacement applications, cable size should be selected in excess of or equal to the replaced cable size. Existing cable space limitations should then be determined to ensure that space for installation of the replacement cable is adequate.

A Ampacity of single-conductor cable in air at ambient temperature of 30°C and maximum conductor temperature not exceeding 60°C.

R Temperature correction: the conductor resistance may be corrected for moderate temperature differences from the noted reference temperature by the following equation. The parameter, \( \alpha T \), varies with conductivity and temperature. For a list of common temperature coefficients see Test Methods B 193.

\[
R_T = R_t [ 1 + \alpha_T (T - t) ]
\]

where:

- \( R_T \) = resistance at reference temperature \( T \),
- \( R_t \) = resistance as measured at temperature \( t \),
- \( \alpha_T \) = known or given temperature coefficient of resistance of the conductor being measured at reference temperature \( T \). At 20°C, the value is 0.003 93,
- \( T \) = reference temperature, and
- \( t \) = temperature at which measurement is made.

An asterisk (*) indicates preferred sizes for wires of American Wire Gauge or per IEC 60228 (metric) as appropriate.
Standard Specification for
Pneumatic-Operated, Globe-Style, Control Valves

This standard is issued under the fixed designation F 1985; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design, construction, testing, and operating requirements for pneumatic-operated, globe-style, control valves complete with actuators for various fluid systems (steam, gas, and liquid applications). The control valves with actuators may be procured under this specification complete with all associated pneumatic instrumentation necessary for the valve to function in the system application; however, complete and detailed requirements for air instrumentation are beyond the scope of this specification and thus are not included here. This specification is not intended to cover quarter-turn or multi-turn stem valves.

1.2 The values stated in metric units (SI) are to be regarded as standard. The values given in parenthesis (inch/pound) are provided for information purposes.

2. Referenced Documents

2.1 The most recent edition or revision of the following standards or specifications shall, to the extent specified in this specification, form a part of this specification.

2.2 ASME Standards:

2.7 ISA Standard:
- ISA-S75.05 Standard for Control Valve Terminology⁶

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

---

² This specification is under the jurisdiction of ASTM committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.11 on Machinery and Piping Systems.

⁴ Available from American Society of Mechanical Engineers, 345 E. 47th St., New York, NY 10017.

⁶ Available from International Society for Measurement and Control, 67 Alexander Dr., PO Box 12277, Research Triangle Park, NC 27709.
3.1.1 actuator—the unit that converts a pneumatic pressure signal into a force to position the valve plug.

3.1.2 bonnet—the upper portion of the valve body subassembly to which the yoke attaches. The bonnet contains the valve stem packing.

3.1.3 dead band—the range through which input signal can be varied, upon reversal of direction, without an observable change in the valve stem position.

3.1.4 equal-percentage opening—an equal-percentage flow characteristic of a control valve provides a change in flow, with the change in valve lift, that is a constant percentage of the flow before the change was made.

3.1.5 flow coefficient \( (C_V) \)—A basic capacity rating for valves that relates flow rate to the inlet and outlet pressure for a particular fluid in the full-open position of the valve. It is defined as the number of litres per seconds (gallons/min) of 16°C (60°F) water that will flow through the valve with a 6.9 kPa (1 psi) pressure drop (\( \Delta p \)) across the valve.

3.1.6 globe-style valve—a basic control valve type that gets its name from the globular shape of its body. It normally uses a basic rising stem/plug for the closure member.

3.1.7 hydrostatic shell test pressure—the hydrostatic test pressure that the valve body is required to withstand without damage or leakage. Valve operation is not required during application of this test pressure, but the valve shall meet all performance requirements after the pressure has been removed.

3.1.8 hysteresis—the maximum difference in output value for any single input value during a calibration cycle, excluding errors as a result of dead band.

3.1.9 instrumentation—the term instrumentation, when used in this specification, refers to any instrumentation, that is, pilot controllers, transmitters, relays, selectors, positioners, instrument air reducing valves, and strainers/filters required for operation of the control valve in the system.

3.1.10 internal trim—internal parts of the control valve, including seat rings, plug, stem, guide bushings, cage, pistons, and so forth.

3.1.11 linear-opening—a linear-opening flow characteristic of a control valve provides a change in flow that is linearly proportional with valve lift.

3.1.12 linearity—the measure of how close a plot of the valve stem travel (in response to an increasing and a decreasing input signal) conforms to a straight line. Linearity is normally expressed as the ratio (in percentage) of the maximum deviation from a straight line connecting the end points of the full operational valve stem stroke.

3.1.13 manual override—the manual override allows valve operation manually. The manual override feature has the ability to oppose and overcome an opening or closing pneumatic control signal in controlling valve position.

3.1.14 pneumatic-operated control valve—a valve installed directly in the fluid system, which translates a pneumatic signal into a change in flow resistance for the system fluid.

3.1.15 pressure rating—the pressure rating of the valve shall be as defined in the documents listed in Table 1. The pressure ratings (also called pressure-temperature ratings) establish the maximum allowable working (service) pressures of a component (valve, end connections, and so forth) at various temperatures.

3.1.16 quick change cage trim—a gasket or an O-ring used in this specification, refers to any instrumentation, that is, pilot controllers, transmitters, relays, selectors, positioners, instrument air reducing valves, and strainers/filters required for operation of the control valve in the system.

3.1.17 quick-opening—a quick-opening flow characteristic of a control valve provides large changes in flow for small changes in valve lift.

3.1.18 rangeability—a measure of the usable range of a control valve and defined as the ratio of the maximum to the minimum controllable \( C_V \). These maximum and minimum controllable \( C_V \) establish the throttling range over which a given control characteristic can be maintained and within which the valve can perform a useful throttling function.
3.1.19 *travel indicator*—the moving pointer mechanically attached to the valve stem and working in conjunction with a fixed indicator scale attached to the yoke.

3.1.20 *three-way valve*—a three-way valve has three end connections configured for converging or diverging flow.

3.1.21 *valve body subassembly*—the combination of valve body, bonnet, end connections, and internal trim.

3.1.22 *yoke*—the intermediate piece between the valve bonnet and the actuator.

3.2 Additional guidance on the control valve terminology can be found in ISA-S75.05.

4. Classification

4.1 Valves shall be of the following material grades, pressure ratings, types, seat leakage classes, flow characteristics, and sizes, as specified in Section 5.

4.1.1 Material Grades (Applicable to Pressure Containing Parts Only):

4.1.1.1 Grade *A*—Alloy Steel—Material Group 1.9 of ASME B16.34 (1 Cr-½ Mo, or 1-¼ Cr-½ Mo).

4.1.1.2 Grade *B*—Carbon Steel—Material Group 1.1 of ASME B16.34.

4.1.1.3 Grade *C*—Corrosion-Resistance Stainless Steel—Material Group 2.2 of ASME B16.34 (18 Cr-8 Ni alloy).

4.1.1.4 Grade *D*—As specified in the ordering information (see Section 5).

4.2 *Pressure Ratings*—Valve shall have pressure ratings selected from those listed in Table 1 and specified in Section 5.

4.3 Types:

4.3.1 Type *1*—Two-way valve, in-line (two end connections).

4.3.2 Type *2*—Two-way valve, angle (two end connections).

4.3.3 Type *3*—Three-way valve, converging service (three end connections—two inlet and one outlet end connections).

4.3.4 Type *4*—Three-way valve, diverging service (three end connections—one inlet and two outlet end connections).

4.4 *Seat Leakage Classes (Maximum Allowable Seat Leakage)*—Seat leakage class shall be selected from those listed in FCI 70-2 and specified in Section 5.

4.5 *Flow Characteristics*—The inherent flow characteristics of the valve shall be specified as quick-opening, linear-opening, equal-percentage opening, or as specified in Section 5. (Additional guidance on valve flow characteristics can be found in ISA Handbook of Control Valves).

4.6 *End Connections*—Valve shall have end connections selected from those listed in Table 1 and specified in Section 5.

4.7 *Sizes*—Valve size shall be as specified in Section 5.

5. Ordering Information

5.1 Ordering documentation for valves under this specification shall include the following information, as required, to describe the equipment adequately:

5.1.1 ASTM designation and year of issue,

5.1.2 Material grade (see 4.1 and Table 1),

5.1.3 Pressure rating (see 4.2),

5.1.4 Pressure drop (Δp), kPa (psi),

5.1.5 Type (see 4.3),

5.1.6 Seat leakage class (see 4.4),

5.1.7 Flow characteristics (see 4.5),

5.1.8 End connections (see 4.6),

5.1.9 Size, inlet, and outlet (see 4.7),

5.1.10 Rangeability (see 7.2),

5.1.11 Line medium (see 6.2),

5.1.12 Operating pressures of the line media (minimum, normal, and maximum) (see 6.16),

5.1.13 Inlet temperature of the line media (minimum, normal, and maximum) (see 6.16),

5.1.14 Flow rate required (minimum, normal, and maximum) (see 7.1),

5.1.15 Replaceable seat ring requirement (see 6.13),

5.1.16 Minimum available air supply pressure to the actuator (see 6.16),

5.1.17 Minimum and maximum actuator control signal pressure, kPa (psi) (benchset of the actuator),

5.1.18 When manual override feature is required, its location—top or side-mounted (see 6.14.3),

5.1.19 Valve fail-position required upon loss of air supply to the actuator (see 6.14.4)

5.1.20 Instrumentation requirements (see 6.15),

5.1.21 Supplementary requirements, if any (see Supplementary Requirements, S1, S2, or S3).

6. Valve Construction

6.1 Valves shall incorporate the design features specified below:

6.1.1 *General Requirements*:

6.1.1.1 Design shall permit adjustment without requiring removal of the valve body from the line.

6.2 *Materials of Construction*—Materials for pressure-containing parts shall be in accordance with the applicable documents listed in Table 1 (see 4.1). Materials for internal parts shall be compatible with the line media specified in Section 5.

6.3 *Pressure Envelope*—The control valve shall be designed to pass a hydrostatic shell test at pressure(s) of at least 1.5 times the 38°C (100°F) pressure rating(s) of the valve without damage.

6.4 *Joints*—The bonnet and bottom cover/flange shall be attached to the body using bolted flanges, a threaded connection, or a threaded-union connection.

6.5 *Valve Springs*—Any spring incorporated in the control valve shall not be compressed solid during operation. Spring ends shall be squared and ground.

6.6 *Threads*—Threads shall be as specified in ASME B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used. Any exposed threads shall be protected by plastic caps for shipping.

6.7 *Interchangeability*—The control valve, including all associated piece parts, shall have part number identity and shall be replaceable from stock by the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s part number shall be directly interchangeable with each other with respect to installation (physical) and performance (functional). Physically interchangeable assemblies, components, and parts are those that are capable of being readily installed, removed, or replaced without alternation, misalignment, or
damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.8 Nonmetallic Element Interchangeability—Nonmetallic elements, including but not limited to, soft-seating inserts, cushions, and O-rings, shall be treated as separately identified and readily replaceable parts.

6.9 Maintainability—Maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified and shall be supplied with the valve when specified.

6.10 Reversibility—Seating inserts shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.11 Pressure-Temperature Ratings—Valve pressure-temperature ratings shall be in accordance with the documents listed in Table 1.

6.12 Stem Seal Assembly—A stem seal assembly shall be provided to seal against leakage along the stem. The stem seal design shall allow the removal of the actuator assembly without disturbing the stem seal assembly.

6.13 Seat Ring—Where required by the service, a seat ring shall be incorporated in the valve and shall be of a material different from the valve body to provide increased resistance to wear, erosion, and leakage. The method of installation of the seat ring shall ensure against dislodgment of the seat ring or leakage between the seat ring and the valve body. Where a replaceable seat ring is required, it shall be specified in Section 5. Unless the method of seat ring retention (for example, quick change cage trim, threaded, brazed, threaded and seal welded, and so forth) is specified in Section 5, it shall be per manufacturer’s standard.

6.14 Actuator Assembly:

6.14.1 Yoke—Yoke construction shall allow easy access to the stuffing box, stem connection, and spring adjuster from either side of the valve. Mounting pads shall be provided on the opposite sides of the yoke for mounting valve positioners or other accessories or both.

6.14.2 Travel Indicator—A travel indicator shall be provided to indicate the valve closure member position.

6.14.3 Manual Override—When specified (see Section 5), manual override shall be furnished. Location (top- or side-mounted handwheel) shall be as specified (see Section 5). A clockwise rotation of the handwheel shall close the valve. The maximum rim force required on handwheel shall not exceed manufacturer’s standards.

6.14.4 Fail-Position Requirement—In the event of loss of actuator air supply, the valve shall proceed to and remain in fail-open, fail-close, or fail-in-position as specified in Section 5.

6.15 Instrumentation—When specified (see Section 5), the valve manufacturer shall furnish with the valve the instrumentation necessary to accomplish the required control functions. The process and pneumatic connection(s) to controller’s pilots or transmitters shall be specified in the ordering data. Intermitent bleed instrumentation shall be used wherever it is compatible with performance, sensitivity, and response speed requirements. Instrumentation interface requirements shall be specified in Section 5.

6.16 Valve Operation—The valve shall operate properly at the operating conditions specified in Section 5. Operating conditions such as operating pressure of line medium, Δp, inlet temperature, and air-supply pressure to actuator shall be supplied in Section 5.

7. Performance

7.1 All valves shall meet the requirements of 7.1.1-7.7.

7.1.1 Capacity—The valve shall be capable of passing the maximum flow rate specified or any intermediate flow rate within the rangeability specified (see Section 5).

7.2 Rangeability—The valve shall exhibit the rangeability specified in the ordering data (see Section 5).

7.3 External Leakage.

7.3.1 Valve—There shall be no visible external leakage from the pressure boundary.

7.3.2 Actuator—There shall be no leakage in the actuator assembly.

7.3.3 Stem—There shall be no visible leakage past the stem.

7.4 Internal Seat Leakage—The seat leakage shall not exceed the leakage specified in FCI 70-2 for its seat leakage class specified in Section 5 (see 4.4).

7.5 Hysteresis—Hysteresis shall not exceed 2 % of valve stroke for valves supplied with or without instrumentation installed.

7.6 Dead Band—Under operating conditions, the dead band shall not exceed 2.4 kPa (0.35 psi) within the full stroke of the stem.

7.7 Linearity—The linearity shall not exceed ±3 % with the instrumentation installed, if the instrumentation is specified in Section 5.

8. Tests Required

8.1 Each control valve shall pass the tests outlined in 8.1.1-8.5.

8.1.1 Visual Examination—The control valve shall be examined visually to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

8.2 Hydrostatic Shell Test—Each control valve shall be hydrostatically tested in the partially open position, by applying a test pressure of not less than 1.5 times the 38°C (100°F) pressure rating to the inlet and outlet ports to check structural integrity. Test pressure(s) shall be applied for 3 min. Air or nitrogen may be used in lieu of water, providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible fluid. There shall be no external leakage (excluding stem-packing leakage), permanent distortion, or structural failure.

8.3 Nondestructive Examination (NDE)—When specified in Section 5, NDE requirements shall be met by performing tests in accordance with the commercial practices listed in ASME B16.34. This shall include radiography testing, magnetic particle testing, dye penetrant, or ultrasonic testing and visual testing as delineated in the above specification.
8.4 Seat Leakage Test—A seat leakage test shall be conducted to verify conformance with the internal seat leakage allowed in 7.4.

8.5 Functional Test—With air pressure applied to the valve actuator, the valve shall be stroked through its entire range of stem travel. Stem travel shall be smooth without sticking or binding. Thereafter, with no air pressure applied to the valve inlet port, the valve shall be tested to verify the minimum air pressure required to initiate stem travel and the maximum air pressure required to complete its full stroke. Air pressure requirements to stroke the valve shall be based upon the operating conditions specified in the ordering information (see Section 5).

9. Marking

9.1 Markings—Valves shall be marked in accordance with MSS SP-25.

10. Quality Assurance System

10.1 The valve manufacturer shall establish and maintain a quality control program following the principles of an appropriate standard from the ISO 9000 series. The need for registration or certification by an independent organization for the valves manufactured under the quality control program shall be determined by the manufacturer. Documentation demonstrating quality control program compliance shall be available to the purchaser at the facility at which the valves are manufactured. A written summary shall be available to the purchaser upon request. The valve manufacturer is the corporate entity whose name or trademark appears on the valve.

10.2 The purchaser reserves the right to witness the production tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

11. Technical Data Requirements

11.1 Drawings—Assembly drawings, information sheets, or catalog sheets shall be provided to indicate the design and materials used in the valve for approval by the purchaser.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements, S1, S2, or S3 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. Supplemental Tests

S1.1 Supplemental tests shall be conducted at a facility satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.1 through S1.5 and delineated in the ordering data. The supplemental tests may be conducted only on representative valve sizes and pressure classes to qualify all sizes and pressure classes of valves, provided the valves are of the same type and design. Evidence of prior approval of these tests may be acceptable.

S1.1.1 Flow Tests—A flow test shall be conducted to determine the valve $C_v$ and the flow characteristic of the control valve.

S1.2 Operational Tests:

S1.2.1 The valve shall be operationally tested as follows:

S1.2.1.1 The valve shall be assembled. Stuffing box nuts shall be finger tight with packing installed or with the packing removed; the valve body shall be at atmospheric pressure. Tapping the valve to remove friction is not permitted.

S1.2.1.2 Hysteresis shall be tested at 25 and 75 % of stroke. At any stroke position, a change of air pressure of 1.7 kPa (0.25 psig) (excluding dead band) in either direction shall cause the valve stem to move. If an automatic hysteresis loop record is obtained, the maximum difference in valve position between increasing and decreasing pressures shall not exceed 2 % of stroke (see 7.5).

S1.2.1.3 Linearity of travel shall be tested at 0, 25, 50, 75, and 100 % of stroke. The relationship between air pressure and stem travel shall be linear to within ±3 % (see 7.7).

S1.3 Shock Test—The control valve shall be subjected to the high-impact shock tests as specified in MIL-S-901 and MIL-STD-798 while pressurized with water, air, or nitrogen to determine its resistance to high-impact mechanical shock. The detail requirements of MIL-S-901 and MIL-STD-798 shall be delineated in the ordering information. There shall be no visible structural damage to the control valve or any of its components. There shall be no degradation to the performance capability of the control valve. During impact, an instantaneous, reversible pressure excursion is allowable.

S1.4 Vibration Test—Control valve shall be vibration tested in accordance with Type I of MIL-STD-167-1 while pressurized with water, air, or nitrogen gas. The detail requirements of MIL-STD-167-1 shall be delineated in the ordering information. There shall be no visible structural damage or degradation to the performance capability of the control valve.

S1.5 Posttest Examination—After completion of the shock and vibration testing, the control valve shall be disassembled and material conditions noted. If shock and vibration tests are done successively in sequence, it is not necessary to disassemble and inspect the valves in between the tests.

S2. Technical Data Requirements

S2.1 Drawings—Assembly drawings or catalog sheets of the control valve that clearly depict design and material of each part shall be provided.

S2.2 Technical Manuals—A technical manual or instruction booklet shall be provided which provides a description of the
valve, operation and maintenance instructions, calibration valves, and illustrated parts breakdown. It shall include wrench sizes and assembly torque (or equivalent) for all bolting and threaded assemblies and step-by-step disassembly and reassembly procedures.

S3. Special Material, Design, and Performance Requirements

S3.1 Pipe threads shall not be used in control valve construction.

S3.2 Control valve performance shall not be adversely affected by the following line and ambient conditions:

S3.2.1 Quality of Inlet Air/Gas—Air or nitrogen moisture content between the limits of −7°C (20°F) to −51°C (60°F) saturated at maximum rated pressure.

S3.2.2 Ambient Atmospheric Conditions:

S3.2.2.1 Temperature—4°C (40°F) to 49°C (120°F).

S3.2.2.2 Moisture Content—Exposure to atmosphere containing salt-laden moisture.

S3.3 Air Connections—Air connections between the pilot controller, actuator, and other accessories shall be in accordance with MS 16142, straight-thread and O-ring seal.
1. Scope

1.1 This test method covers shipboard, fixed (installed) foam/sprinkling firefighting systems.

1.2 Satisfactory completion of these tests indicates functional performance of the fixed foam firefighting system and may be used to demonstrate the system installation’s compliance with the design characteristics of the system.

1.3 Tests made in conformity with this test method are intended to demonstrate the installation and operation of an installed, fixed foam firefighting system. As it includes regulatory requirements, this standard addresses those vessels subject to regulations and ship classification rules. However, the methods stated herein are suitable for unregulated commercial vessels, pleasure craft, military vessels, and similar vessels that are not required to meet regulations for firefighting systems.

1.4 Limitations:

1.4.1 International requirements, national regulations, and ship classification rules must be consulted. The following regulatory requirements and classification society rules were considered in the preparation of this test method:

1.4.1.2 U.S. Government regulations included in 46 CFR 76, 46 CFR 95, and 46 CFR 108 as those regulations are written and enforced by the United States Cost Guard, and

1.4.1.3 The American Bureau of Shipping (ABS) Rules for Building and Classing Steel Vessels. However, the owner will designate the specific classification society which is to be used to classify a particular vessel.

1.4.2 The requirements, regulations, and rules for a specific design must be selected by the owner based on the planned operating profile for the vessel.

1.4.3 This test method reflects international requirements, U.S. Government regulations, and ABS rules in effect at the time it was prepared, and may not include requirements adopted subsequent to the effective date of this test method.

1.4.4 This test method does not include requirements for the selection, design, installation, and maintenance of foam firefighting systems. It applies to installed systems whose designs meet all applicable international requirements, national regulations, and ship classification rules.

1.5 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 The following documents apply to this test method only to the extent referenced herein. However, they may be further invoked by the ship owner as part of the design requirements for the vessel.

2.2 ASTM Standards:

A 795 Specification for Seamless Steel Pipe for Fire Protection Use

F 998 Specification for Centrifugal Pumps, Shipboard Use

F 1030 Practice for Selection of Valve Operators

F 1155 Practice for Selection and Application of Piping System Materials

F 1198 Guide for Shipboard Fire Detection Systems

F 1333 Specification for Construction of Fire and Foam Station Cabinets

F 1370 Specification for Pressure-Reducing Valves for Water Systems, Shipboard

F 1508 Specification for Angle Style, Pressure Relief Valves for Steam, Gas, and Liquid Services

F 1510 Specification for Rotary Positive Displacement Pumps, Commercial Ships Use

F 1547 Guide Listing Relevant Standards and Publications for Commercial Shipbuilding

2.9 SNAME Bulletins:
3. Terminology
3.1 Refer to Annex A1 for terminology used in this test method related to fixed foam firefighting system installations and their testing. Actual terminology used for fixed foam firefighting systems may vary depending upon the desires of the owner or system designer, or both.

4. Significance and Use
4.1 This test method is applicable to fixed foam firefighting systems, including foam generation equipment, foam distribution system piping and valves, sprinkler arrangement and operation, hose reel unit operation, and system controls, as those components are included in the system for a particular application.

4.1.1 Foam systems for machinery spaces are tested using those portions of this test method which apply to the installed components. Suitable adaptation of this test method is made for use with systems which do not include all hardware components described herein.

4.1.2 Deck foam systems are tested per the manufacturer’s design criteria.

4.2 This test method demonstrates: satisfactory installation of an entire fixed foam/sprinkling system and its associated controls; and effective operation of portions of the foam distribution system and foam maker sprinkling nozzles for selected zones.

4.2.1 This test method verifies application rates and areas of coverage for each type of discharge device of the fixed foam firefighting system.

4.2.2 The satisfactory operation of the system in the selected zones is a measure of overall system capacity and anticipated operation for emergency use. The test, however, may not be representative of all emergency operating conditions that may vary with changes in the number of zones that are activated simultaneously, the material condition of the distribution and sprinkling components as they are maintained over time, and restoration of the system following its use for testing or actual emergencies.

4.3 Test procedures shall be prepared for the conduct of tests of foam firefighting systems in specific vessels. Those procedures shall be tailored to the system design for the system as installed and operated in each vessel.

4.3.1 Tests accomplished in accordance with approved test procedures may be sufficient to demonstrate that the vessel meets the regulatory and classification requirements for the vessel.

4.3.2 Approval of test procedures by a classification society may be necessary.

4.3.3 Test procedures must state operating parameters and values (for example, flow rate, pressure, time to activate) which define pass/fail criteria for each test.

4.4 Certification of the vessel or classification of the vessel or both by the regulatory bodies may require that tests be witnessed by a marine inspector or surveyor or both who represents both regulatory bodies.

4.5 Interpretation of Results:
4.5.1 Leakage at any piping system mechanical joint that is corrected “on-the-spot” is not cause for test rejection.

4.5.2 Any erratic operation detected in the zone control valves, seawater sprinkling pump discharge bypass-overboard valves, or control devices is cause for rejection of the test. The component causing the erratic operation shall be repaired or replaced and a retest performed.

4.5.3 Any operation which does not meet the pass/fail criteria defined by the test procedure(s) is cause for rejection of the test. The cause of the failure shall be determined, the design or installation, or both, corrected as appropriate, and a retest performed.

5. Hazards
5.1 Safety Hazards—The following safety precautions must be taken when conducting tests in accordance with test procedures that conform with this test method. However, this is...
not an inclusive listing of all hazards which may occur when
this test method is followed, see 1.5. Appropriate safety hazard
statements must be included in test procedures that conform
with this test method.

5.1.1 Live control circuits are exercised during tests per-
formed in accordance with this test method. This can result in
the inadvertent discharge of seawater or seawater/foam solu-

5.1.1.1 Remote operation of valves which allow discharge
of fluids directly into interior spaces of the vessel is required.
5.1.1.2 Tag out electrical circuits or tag closed valves as
appropriate for each test.
5.1.2 The fixed foam firefighting system includes relief
valves and pressure-regulating valves which limit the internal
pressures to which piping and valves of the system are
subjected. Failure of these devices to control or limit system
pressure may result in component failures.
5.1.3 The following safety and control devices are required
to conduct the tests:
5.1.3.1 Pumps’ relief valves;
5.1.3.2 Seawater sprinkling pump discharge bypass-
overboard relief valves which must be set in accordance with
the maximum system operating pressure; and
5.1.3.3 Zone sprinkling control, remotely operated valves,
as applicable.
5.1.4 All precautions to ensure safety of life and equipment
protection in compliance with the industrial facility’s and
vessel’s established safety precautions shall be followed at all
times in the conduct of foam firefighting system tests.
5.1.5 Portions of the fixed foam firefighting system should
not be disabled or isolated for tests until just before the a
specific test event is scheduled to commence. This will leave
the system functional for use in case of an actual fire.
5.2 Precautionary Statements—The following precautions
should be taken when conducting tests in accordance with test
procedures which conform with this test method. Appropriate
precautions and warning statements must be included in test
procedures that conform with this test method.
5.2.1 All appropriate electrical circuits must be de-
energized and tagged when doing any test or demonstration
involving contact with electrical conductors.
5.2.2 It is against environmental regulations to discharge
seawater/foam solutions within 3 miles of shore in the United
States. Care must be taken to prevent discharge of foam into
coastal waters of any country. Therefore, all in-port testing is to
be accomplished using fresh water or clean seawater. Foam
concentration testing, by dispersion of actual seawater/foam
solution, is to be accomplished only when underway, well
outside coastal waters, or the seawater/foam solution is dis-
charged to a containment vessel for disposal in conformance
with local regulations.
5.2.3 Sprinkling or other discharge into interior spaces can
lead to water or seawater/foam solution accumulation. Vessel
stability can be dangerously affected if dewatering systems are
not fully functional and operating. Operators must closely
monitor the amount of water accumulated on deck during any
phase of demonstrations or testing. Demonstrations or testing
should be suspended if such accumulation cannot be controlled
and sufficient stability maintained.
5.2.4 All equipment or surfaces that could be damaged by
water during testing, in way of hose reel discharge areas or in
zones where fresh water or seawater/foam solutions will be
discharged from foam maker sprinkling nozzles, or both,
should be covered with plastic or otherwise protected from the
discharge.
5.2.5 Any piping flanges that formerly were blanked to
conduct hydrostatic testing of the foam distribution system
should be inspected for tightness during the operational tests.
5.2.6 Precaution shall be taken to ensure proper valve
alignment to prevent flooding the vessel during any test
requiring operation of the seawater sprinkling system, seawater
sprinkling pumps, foam proportioning pumps, and foam con-
centrate transfer pumps.
5.2.7 Any tests requiring seawater or seawater/foam solu-
tion to be pumped through foam distribution system piping
shall be conducted only after precautions have been taken to
insure the watertight integrity at the maximum system operat-
ing pressure of all affected piping and valves.
5.2.8 Appropriate zone control valves shall be tagged closed
during in-port testing to preclude accidental discharge of foam
concentrate entering the distributive system or being dis-
charged overboard.
5.2.9 Isolate system areas or zones that are not used in a
specific test.
5.3 Remedial Statements—System restoration following
demonstrations should include the following actions.
5.3.1 Restore all electrical power to the pumps and controls.
Ensure that all electrical and control circuits are set for normal
operation.
5.3.2 Ensure that tags installed on remotely operated valves
have been removed.
5.3.3 Ensure that all distribution piping and valves are
aligned for normal operation.
5.3.4 Clean up all areas and equipment that may have been
wetted by sprinkling or flooding incidental to these demonstra-
tions.
5.3.5 Remove any “socks” or other devices installed to
contain water or foam discharged during demonstrations.
5.3.6 Remove any test instrumentation or gauges installed
for the demonstrations.
5.3.7 Ensure that foam concentrate tanks are filled with
foam concentrate.

6. Overview of Fixed Foam Firefighting System Tests
6.1 There are two phases of testing the fixed foam and
seawater sprinkling system: system installation tests and sys-
tem operational tests.
6.2 Installation testing is intended to demonstrate the integ-
rity of the system as it was installed in the vessel. It comprises
a series of tests to demonstrate that the foam/sprinkling system
is completely installed. It is essential that this testing be
completed before accomplishing any operational tests using
seawater or foam.
6.3 Operational testing is intended to demonstrate that the
system operates in each of its designed modes of operation.
System operational testing is accomplished through a series of
individual tests to exercise all elements of the system. Some tests will be performed with the vessel in port; other tests will be done with the vessel underway.

7. Prerequisite Requirements

7.1 The following test materials are required to conduct the test:

7.1.1 Freshwater, sufficient to fill repeatedly all foam concentrate tanks for in-port tests.

7.1.2 Foam maker pressure test fittings composed of the following: adaptors to install the fitting in-line with a sprinkler nozzle with branch connection to a globe needle valve and pressure gage.

7.1.3 Sufficient foam concentrate to conduct demonstrations and tests called for within this standard.

7.2 The following equipments and systems are involved in the testing. Required testing of individual equipments shall have been completed before testing the foam firefighting system.

7.2.1 All seawater and sprinkling/foam distribution system and transfer system piping in the foam firefighting system.

7.2.2 All installed foam proportioners and foam concentrate tanks.

7.2.3 Foam concentrate, foam concentrate transfer, and seawater sprinkling pumps.

7.2.4 Foam maker sprinkling nozzles, hose reels, and zone control valves.

7.2.5 Damage control console (DCC) or other central control station operating controls, local control station control panels, and fire control station operating controls.

8. Preparation for Testing

8.1 The following prerequisite testing shall have been completed satisfactorily before commencing system tests of the foam firefighting system.

8.1.1 Control System—Testing of the central control station’s DCC, including any remote alarms or operations conducted through the DCC, shall have been completed using any separate test procedures developed for that equipment.

8.1.1.1 Such testing may be accomplished in accordance with Guide F 1198 and should meet the test requirements of that guide.

8.1.1.2 Ensure continuity of all electrical signal or fiber optic cable connections from the DCC to each remotely operated valve and its associated local control panel, the fire control station, and each foam proportioning station and its associated pumps and valves.

8.1.2 Piping and Valves—Testing of individual piping runs and valves, including hydrostatic tests, shall have been completed using any separate test procedures developed for fluid distributive systems. Documentation should be provided before starting the foam system tests.

8.1.2.1 Pipe and valves used for foam distribution should meet the test requirements of the material specifications for items cited by Table 10, “Dry Fire Main, Foam, Sprinkling, Deckwash, Tank Cleaning Piping,” of Practice F 1155.

8.1.2.2 The piping associated with foam proportioners seawater valves should meet the testing requirements of Specification A 795.

8.1.2.3 Remotely operated valve operators should be meet the testing requirements of Practice F 1030.

8.1.2.4 Pressure regulating valves should meet testing requirements for pressure-reducing valves such as those found in Specification F 1370.

8.1.2.5 Relief valves, when a component of piping systems, should meet the test requirements of Specification F 1508.

8.1.2.6 Butterfly-type quick acting valves should meet the testing requirements of ANSI B16.34.

8.1.3 Operating Stations—Testing of the following operating stations to ensure electrical power is available, continuity of electrical signal or fiber optic cable connections between the DCC and the remotely controlled valve(s) or pumps, and proper operation of the control consoles or panels at each station shall have been completed using any separate test procedures developed for that equipment.

8.1.3.1 Fire control station, including signal connections to the foam proportioning stations,

8.1.3.2 Foam proportioning stations,

8.1.3.3 Zone control stations, including signal connections to the foam proportioning stations, and

8.1.3.4 Hose reel unit controls, including signal connections to the foam proportioning stations.

8.1.4 Foam Transfer Stations—Testing of individual components, including hydrostatic tests, shall have been completed using the separate test procedures for foam transfer stations. Pipe and valves used for foam transfer should meet the testing requirements of the material specifications for items cited by Table 10, “Dry Fire Main, Foam, Sprinkling, Deckwash, Tank Cleaning Piping,” of Practice F 1155.

8.1.5 Test relief valves and pressure-regulating valves for proper settings. Components such as pumps that have integral relief valves or bypass valves may have such valve settings verified as part of testing that component.

8.2 The following actions shall have been completed before commencement of tests of the applicable portions (or all) of the foam firefighting system. (Warning—Safety procedures shall be followed to tag out electrical circuits or tag closed valves as appropriate for that portion of the test.)

8.2.1 Isolate system areas that are not used in a specific portion of the test. (Warning—Close and tag valves to isolate portions of the system including zones and hose reel units that will not be tested. Visually confirm all designated valves are closed.)

8.2.2 Install the test fittings (see 7.1.3) in the hydraulically most remote foam maker nozzles between the reducer from the branch connection and the nozzle inlet. Install pressure gages. Adjust the isolation valves as necessary during conduct of the test to obtain readings without excessive pressure fluctuation or water hammer.

9. Conduct of System Tests

9.1 Foam Concentrate Tank Hydrostatic Test—Verify there is a certification of the tank that it will withstand, at a minimum, the hydrostatic pressure to be seen as it is installed in the system. Lacking such certification, the foam concentrate tank shall be tested as follows.

9.1.1 Temporarily blank all openings except the overflow piping. Fill the tank with fresh water to the top of the overflow
9.1.2 Upon completion of the hydrostatic test, remove all temporary blanks or plugs, or both. Freshwater may be retained for use during pump operational tests and hose reel tests.

9.1.3 All tanks and associated piping must be drained of all water before the introduction of foam concentrate into the tanks.

9.2 Pump Installation Test—Each seawater sprinkling pump and foam concentrate pump shall be tested.

9.2.1 Ensure that each pump and motor shaft alignment is completed and that the pump rotates freely when turned by hand.

9.2.2 Verify integrity of all piping and electrical connections to each pump and its motor.

9.3 Pump motor and controller operational tests: each seawater sprinkling pump, foam concentrate pump, and foam concentrate transfer pump shall be tested.

9.3.1 Perform insulation resistance checks before (cold) and after (hot) the operational test. (Warning—Ensure all electrical power is secured to pump motors before conducting insulation resistance checks.)

9.3.2 Conduct an operational test with the pump and motor unit running and the system aligned to provide continuous operation. Pump and motor operation shall be without indications of internal rubbing (for example, noise or vibration) or other external signs of degrading performance. Pump output pressure shall be constant over the operating period. Motor amperage shall not exceed name plate data during steady state operation.

9.3.3 Additional requirements for seawater sprinkling pump tests. (Warning—Ensure seawater isolation valves to the foam proportioners and its seawater bypass are closed and tagged.)

9.3.3.1 Align the pump to take suction from the sea and discharge overboard.

9.3.3.2 Seawater sprinkling pump relief valves should be set at the design operating pressure. Pressure control valves should be adjusted so that the valves control pressure changes to design criteria.

9.3.3.3 Demonstrate operation of sprinkling pump’s associated remotely operated valves by running the pump with system isolation valves closed. Ensure overboard isolation valves are fully open and discharge pressure gauges indicate the design operating pressure.

9.3.4 Additional requirements for foam concentrate pump tests.

9.3.4.1 Foam concentrate pumps and seawater sprinkling pumps typically are tested simultaneously because they do not have individual controllers. In such instances, they both are started together at the master controller.

9.3.4.2 Ensure that the foam concentrate isolation valves to the foam proportioner are closed and tagged. Fill the foam concentrate tank with freshwater or foam concentrate to an adequate level to assure continuous suction. Align the pump to take suction from the tank and discharge back into the tank.

9.4 Zone control valve and hose reel unit operational demonstrations: Each zone control valve and hose reel unit shall be tested. (Warning—In addition to other precautions, the following steps are to be taken prior to demonstrations.)

9.4.1 Secure electrical power to the foam concentrate pumps. Ensure that appropriate remotely operated valves are closed and tagged. Set up the system for SEAWATER operation before initiating each OPEN command.

9.4.1.1 Ensure that all distribution piping downstream of the proportioners is aligned for normal operation.

9.4.1.2 Provide protection for all areas and equipment that may be water damaged by sprinkling or flooding incidental to these demonstrations.

9.4.1.3 Ensure that the vessel’s dewatering system(s) is fully functional and operating in areas where liquids might be discharged. (Warning—The amount of liquid on deck should be closely monitored during these demonstrations.)

9.4.2 Demonstration of hose reel units, if installed in the vessel.

9.4.2.1 Demonstrate the ability of each hose reel control START command to activate the sprinkling/foam system. Ensure the start-up sequence is accomplished by observing the seawater sprinkling pump master controller.

9.4.2.2 Verify seawater exits satisfactorily from the hose nozzle.

9.4.3 Demonstration of zone control valves. Demonstrate the ability of each zone control OPEN command to activate the sprinkling/foam system. Demonstrate the ability to secure each zone with CLOSE commands.

9.4.3.1 Ensure the start-up sequence is accomplished by observing the seawater sprinkling pump master controller. Observe operation of the remotely operated valve by moving from the fully closed to the fully open position and from fully open to the fully closed position.

9.4.3.2 Initiate local activation by initiating the OPEN command using each zone control local station. Close the remotely operated valve by initiating the CLOSE command.

9.4.3.3 Initiate remote activation with an OPEN command from DCC for each zone control valve. Close each remotely operating valve by initiating the CLOSE command.

9.4.3.4 Demonstrate operation of engine room bilge sprinkling and any other engine room foam systems from the fire control station. Initiate activation with an OPEN command; close the remotely operated valves by initiating the CLOSE command.

9.4.3.5 After the remotely operated valve for a particular zone is closed, secure the seawater sprinkling pump before the next demonstration of that zone or a different zone. Only one zone should be demonstrated at a time to verify proper coordination of the OPEN commands and activation of the seawater sprinkling pump.

9.5 Sprinkling/foam system operational test: A full operational test of the entire system shall be conducted before the vessel getting underway.

9.5.1 Prior to the test, complete the following steps.

9.5.1.1 Determine the two zones with the highest combined flow rate. If one or both of these zones are interior to the vessel, and two or more zones that are in weather will develop the
same or higher flow rates, the weather zones may be tested in lieu of two interior zones.

9.5.1.2 Determine the two foam maker nozzles that are hydraulically most remote from each foam proportioning station. Install test fittings (see 7.1.2) on those nozzles.

9.5.1.3 Isolate all zone control valves that will not be included in the test. (Warning—In addition to other precautions, provide protection for all areas and equipment that may be water damaged by sprinkling or flooding incidental to this test. “Socks” or other devices may be installed to contain the discharge from foam maker nozzles and directly route it to an area in which such discharge will be collected.) (Warning—The vessel’s dewatering system(s) must be fully functional before conduct of these demonstrations. The amount of liquid on deck should be closely monitored during these demonstrations.)

9.5.1.4 Verify that the seawater sprinkler pump sequential start time delays have been set. The primary foam proportioning station’s pump start sequence must have a shorter time delay than the secondary foam proportioning station’s pump.

9.5.1.5 Ensure that all foam concentrate tanks are filled with freshwater and that the tank levels are recorded. This step must accomplished for the demonstration of each foam proportioning station and must be repeated for the full system demonstration.

9.5.1.6 Ensure that educators, pumps, or other equipment needed to dewater the vessel during and after testing are in proper working order.

9.5.2 Demonstrate the ability of each foam proportioning station to be locally started and stopped using the seawater sprinkling pump master controller.

9.5.3 Demonstrate the ability of each foam proportioning station to be remotely started and stopped using commands from DCC.

9.5.3.1 In accordance with the design, demonstrate the proper mode is activated when the SEAWATER mode or FOAM mode is selected.

9.5.3.2 When a SEAWATER mode selector is provided, ensure that the foam proportioning station, when operated in the SEAWATER mode, defaults to the FOAM mode when it is secured.

9.5.4 Demonstrate the ability of each foam proportioning station to deliver fresh water (in lieu of using foam concentrate). Isolate other foam proportioning stations from the system during these demonstrations.

9.5.4.1 Locally start the pumps for a foam station in the SEAWATER mode. When good flow has been established to the selected zone, switch from the SEAWATER mode to the FOAM mode. Operate in the FOAM mode for 20 min and secure the Foam Proportioning Station.

9.5.4.2 Select the single zone requiring the highest flow rate (see 9.5.1.1). Determine the pressure reading at the most distant nozzle in that zone. Verify full flow from all nozzles in the selected zone.

9.5.4.3 Determine the pressure reading at the two hydraulically most distant nozzles from the foam proportioning station (see 9.5.1.2), regardless of the zone in which located. The minimum pressure shall not be less than that specified by the manufacturer of the foam maker nozzle for proper operation of the nozzle.

9.5.4.4 Excess water should be dumped overboard during the test of each foam proportioning station. Verify the design operating pressure is available at all times at the outlet main from the station.

9.5.5 Conduct a foam concentrate transfer demonstration. It should be conducted only after all tests requiring that freshwater be used in the foam concentrate tanks have been completed satisfactorily. This demonstration is to be conducted using foam concentrate only.

9.5.5.1 Remove all water from the foam concentrate tank, from the foam concentrate piping serving the proportioners, and from the foam transfer piping.

9.5.5.2 Demonstrate the operation of the hand transfer pump at each foam proportioning station. Using the hand transfer pump, transfer foam concentrate from a bulk shipping drum or barrel to the foam concentrate tank. Empty the drum.

9.5.5.3 Demonstrate the operation of each motor driven, foam concentrate transfer pump, if such pumps are installed in the vessel.

(a) (a) The operational test (see 9.3.2) should be completed before commencing this demonstration.

(b) (b) Conduct an operational demonstration of the pump by aligning it to take suction from the foam tank and discharge either back into the foam concentrate tank or to the concentrate tank at another foam proportioning station.

(c) (c) Fill the foam concentrate tank in one of the foam proportioning stations to at least half full. Demonstration transfer of concentrate by using the concentrate transfer pump to transfer all of the concentrate to another station.

9.5.6 Additional requirements for foam concentrate transfer pump tests, if installed in the vessel. (Warning—Ensure all appropriate remotely operated valves are closed and tagged to prevent contamination of the foam concentrate with freshwater or seawater.

9.5.6.1 Verify setting of the relief valve for the pump.

9.5.6.2 Fill the foam concentrate tank for the foam proportioning station with foam concentrate. Align the transfer pump to take suction from the tank and discharge either back to the tank or to another foam station. Commence an operational test of sufficient duration for the pump to have completely drained the tank twice, with the pump operating at its rated capacity. During the final portion of that test, transfer sufficient foam concentrate to another foam proportioning station to observe a change in level in that station’s tank.

9.5.6.3 Repeat the test for the transfer pump at each foam proportioning station until all stations have been tested.

9.6 Foam Concentrate Tests—A full operational test of the entire system shall be conducted with the vessel underway.

9.6.1 Before the full system operational test, complete the following steps.

9.6.1.1 Determine the two zones with the highest combined flow rate (see 9.5.1.1). Weather zones may be tested in lieu of interior zones.

9.6.1.2 Isolate all zone control valves that will not be included in the test. This should not be done until immediately
prior to the test to allow the zones to be used in case of actual emergency. (Warning—Provide protection for all areas and equipment that may be water damaged by sprinkling or flooding incidental to this test.)

9.6.1.3 Ensure that all foam concentrate tanks are filled with foam concentrate and that the tank levels are recorded.

9.6.2 Conduct the full operational test. This test will require the simultaneous operation of all foam proportioning stations, using foam concentrate. (Warning—The amount of liquid that accumulates on deck should be closely monitored during this test.)

9.6.2.1 If provided with a SEAWATER mode selector, start the seawater sprinkling pumps in the SEAWATER mode. When good flow has been established to all selected zones, switch from the SEAWATER mode to the FOAM mode.

(a) (a) Operate in the foam mode for at least 3 min after foam comes out of the nozzles.

(b) (b) Secure the foam proportioning station after samples have been taken.

(c) (c) Collect samples of the foam from the most and least remote locations in each zone. Samples are to be taken after 3 min of foam discharge.

(d) (d) Samples shall be analyzed to determine that the proper foam concentrate percentage is achieved at all locations throughout the test, as per design. Foam samples are to be tested for concentration in accordance with NFPA standard.

9.6.2.2 Excess water should be dumped overboard during the test of each foam proportioning station. Verify the design operating pressure is available at all times at the outlet main from the foam proportioning station.

9.6.2.3 Demonstrate the operation of each hose reel unit, if any are installed in the vessel. Accomplish the following when demonstrating of the hose reel(s):

(a) (a) Operate in the foam mode for 10 min.

(b) (b) Collect samples of the foam. Samples are to be taken after 5 and 10 min of operation. Samples shall be analyzed, in accordance with NFPA standard, to determine that the proper foam concentrate percentage is achieved throughout the test.

(c) (c) Drain the system when the test is complete.

10. Ordering Information

10.1 Ordering documentation for testing foam firefighting systems in accordance with this standard test method shall include the following information, as required, to describe the system adequately.

10.1.1 ASTM designation and year of issue,

10.1.2 Specifications for testing various components of the system,

10.1.3 Number of foam proportioning stations in the system,

10.1.4 Number and type of pumps in the system,

10.1.5 Number and service location of hose reel units in the system,

10.1.6 Prerequisite test requirements based on specifications invoked for components of the system, as described in 8.1,

10.1.7 Regulation accuracy required, if other than given in 3.5,

10.1.8 Pressure and capacity requirements, if specified by the owner, and

10.1.9 Foam system design USCG certification, if applicable.

11. Report

11.1 Report the following information:

11.1.1 Name of the industrial facility conducting the tests;

11.1.2 Date of tests and demonstrations;

11.1.3 Set of design drawings describing installation of the foam firefighting system and associated controls;

11.1.4 Nameplate data for each pump, motor, and controller;

11.1.5 Numerical data in tabular and graphic form (with identification of limits or pass/fail criteria):

11.1.5.1 Pump installation alignments;

11.1.5.2 Operational test data including: motor voltage, motor amperage, motor insulation resistance, revolutions per minute, pump suction and discharge pressures, and, any unusual conditions noted.

11.1.5.3 Identification of all hose reels demonstrated;

11.1.5.4 Identification of all sprinkling zones demonstrated for local and remote operation;

11.1.5.5 Time delays for foam proportioning station pumps;

11.1.5.6 Identification of foam proportioning stations demonstrated for local and remote operation;

11.1.5.7 Results of in-port testing using fresh water in lieu of foam concentrate: capacity of each foam concentrate tank, level of fresh water in each tank at start and conclusion of the demonstration for each zone, zones used in the demonstrations, pressure readings at most remote nozzles, and, any unusual conditions noted;

11.1.5.8 Results of underway testing using foam concentrate: seawater/foam measured ratios for each sample taken, zones used in the demonstrations, hose reels demonstrated, and any unusual conditions noted.

11.2 Report the following information for each failure to meet the accept/reject criteria of the test procedures:

11.2.1 Specific metrics of the failure,

11.2.2 Description of action(s) taken to correct the failure, and

11.2.3 Results of the retesting of all failed portions of the test procedure, including any applicable data of 11.1.

12. Precision and Bias

12.1 Precision—It is not possible to specify the precision of the procedure in this test method for fixed foam firefighting systems because results will vary from vessel to vessel or may vary for the same system on a single vessel owing to:

12.1.1 The test instrumentation and test setup will vary;

12.1.2 The designs of different systems will produce different values; and

12.1.3 The test procedures prepared by different industrial facilities that perform the testing over the life of the vessel.

12.2 Bias—No information can be presented on the bias of the procedure in this test method for fixed foam firefighting systems because of variances in the design of each vessel’s installation.
A1. TERMINOLOGY: GLOSSARY OF TERMS USED IN THIS TEST METHOD FOR FOAM FIREFIGHTING SYSTEMS

A1.1 Use of This Glossary of Terms:

A1.1.1 Test requirements associated with the terms described in this annex are for reference only. Specific test requirements are imposed using the ordering data for individual components.

A1.1.2 These terms are for reference only; components of a particular fixed fire fighting system may be identified by different nomenclature as part of the system design.

A1.2 Terms used in this test method for fixed foam firefighting systems.

A1.2.1 bias—the difference between the average measured test result and the accepted reference values (or accept/reject criteria); it measures in an inverse manner the accuracy of a test.

A1.2.2 bilge sprinkling system—a fixed foam sprinkling system in the bilges of a machinery space; includes distribution piping and foam maker sprinkling nozzles.

A1.2.3 control system—the electrical system used to monitor and control all of the equipment associated with the foam firefighting system. The control system includes the panels and consoles from which the foam fighting system can be operated and the interconnecting electrical signal cables or fiber optics.

A1.2.4 damage control console (DCC)—the central console in the control system at which the firefighting system can be monitored and controlled. Such console may be part of a fire detection system installation.

A1.2.5 foam concentrate—liquid solution that is mixed with seawater to make fire fighting foam.

A1.2.6 foam distribution system—the piping and valves that distribute seawater/foam solution from foam proportioning stations to nozzles or hose reels throughout the vessel, or both.

A1.2.7 fixed foam firefighting system—the tanks, pumps, interconnecting piping, foam distribution system piping and valves, local controls, foam maker sprinkling nozzles, and hose reels to provide seawater/foam solution to fight fires.

A1.2.8 foam maker sprinkling nozzle—a nozzle that mixes air with seawater/foam solution to sprinkle foam.

A1.2.9 foam proportioners—a unit that mixes foam concentrate and seawater in the proper proportions to make seawater/foam solution.

A1.2.10 foam transfer system—the pumps, piping, and valves that are used to transfer foam concentrate from one foam proportioning station to another.

A1.2.11 hose reel unit—a fixed unit that includes a reel and drum assembly from which a hose with foam maker nozzle can be deployed to allow portable direction of foam at the site of a fire. Some vessels may use a hose rack in a foam station cabinet such as one described by Specification F 1333 without a local proportioners, using seawater/foam solution from the foam distribution system in lieu of a local foam proportioners.

A1.2.12 local control panel—the panel that controls the valve operator for a zone control valve or hose reel unit isolation valve.

A1.2.13 master controller, seawater sprinkling pump—the motor controller for the seawater sprinkling pump; it also may be the motor controller for the foam concentrate pump.

A1.2.14 precision—a measurement concept that expresses the ability to generate test results that agree with each other in absolute magnitude.

A1.2.15 pressure, design operating—pressure used in design to determine the required minimum thickness and minimum mechanical properties (of the foam firefighting system).

A1.2.16 pressure, hydrostatic head—the static pressure at any point in the system created by a vertical column of liquid from that point to the highest point in system. Alternately, the pressure at any point in a tank created by vertical column of the liquid carried in that tank, from that point to the highest point in the tank vent.

A1.2.17 pressure, maximum system operating—the maximum pressure at which the foam firefighting system can be operated; typically, the highest pressure setting of any pressure relief device in the system.

A1.2.18 pump, foam concentrate—the pump that provides foam concentrate from the foam concentrate tank to the foam proportioners; they typically are Specification F 1510, Class A pumps sized with a capacity to provide foam simultaneously to the two largest zones in the vessel and should meet the test requirements of that specification.

A1.2.19 pump, foam concentrate transfer—a pump used to transfer foam concentrate solution from one foam proportioning station to another; they typically are Specification F 1510, Class A pumps sized with a relatively low capacity and should meet the test requirements of that specification.

A1.2.20 pump, hand transfer—a pump used to transfer foam concentrate from pails or barrels into foam concentrate tanks.

A1.2.21 pump, seawater sprinkling—a pump that takes sea suction and pumps seawater to the foam proportioners; they typically are Specification F 998, Class 5 pumps and should meet the test requirements of that specification.

A1.2.22 seawater/foam solution—a mixture of foam concentrate and seawater in proper proportions to make foam when discharged through a foam maker sprinkling nozzle or hose reel unit foam nozzle.

A1.2.23 station, fire control—the location used to monitor and control all of the equipment associated with the firefighting system in the engine room(s) and casing. The panels or console from which the engine room foam firefighting system can be operated and the interconnecting electrical signal cables or fiber optics are located at this station.
A1.2.24 station, foam proportioning—the location at which seawater/foam solution is generated and from which it is pumped to sprinkling zones, hose reels, and the engine room(s). This station typically includes the seawater sprinkling pump, foam concentrate tank, foam proportioning pump, foam proportioners, foam transfer pump, interconnecting piping and valves, and their controls.

A1.2.25 station foam transfer—a location which includes a pump concentrate transfer pump and control devices necessary to move foam concentrate.

A1.2.26 station, hose reel—a location used to monitor and control a foam hose reel unit.

A1.2.27 station, local control—a location at which an operator can monitor and control the foam sprinkling system in a zone.

A1.2.28 tank, foam concentrate—a tank for bulk stowage of foam concentrate; it is connected to the suction side of the foam concentrate pump.

A1.2.29 valve, bypass-overboard—a valve that allows the discharge of a pump in the fixed foam firefighting system to bypass the foam distribution system and be discharged overboard. Such valves also can function as relief valves which discharge overboard when the system pressure exceeds the valve’s set pressure.

A1.2.30 valve, foam proportioners seawater supply—a valve on the seawater inlet side of a foam proportioners that isolates it from its source of seawater, either the fire main or a seawater sprinkling pump.

A1.2.31 valve, hose reel—the quick opening valve that isolates a hose reel unit from the distribution main or risers for the seawater/foam solution.

A1.2.32 valve, remotely operated—a valve that uses an electric or hydraulic power-actuated operator to change its position. Remotely operated valves in the foam firefighting system can be positioned by either local or remote actuation and can be positioned using a manual operator.

A1.2.33 valve, pressure regulating—a valve that senses total pressure in the distribution piping downstream of the valve and adjusts the flow through the valve to maintain that pressure at a set level.

A1.2.34 valve, relief—a pressure-activated valve designed to relieve excessive pressure automatically. Such valves in the foam firefighting system can be integral to the system’s pumps or be a component of piping systems.

A1.2.35 valve, seawater bypass—the valve that bypasses the foam proportioners, allowing the foam firefighting system to distribute only seawater.

A1.2.36 valve, sprinkling pump seawater suction—the seawater on the seawater side of the seawater sprinkling pump.

A1.2.37 valve, zone control—the quick opening valve that isolates a zone from the distribution main or risers for the seawater/foam solution.

A1.2.38 zone—a section of the foam distribution system that includes all piping, valves, and sprinklers for a defined area of the ship.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Guide for Vessel-Related Technical Information for Use in Developing an Electronic Database and Ship Safety Record

This standard is issued under the fixed designation F 2001; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide provides a uniform format and definition of general vessel-related technical information, including ship safety data, to be used by ship owners and operators, at their option and to the extent that they consider beneficial to their operation. It is recognized that all of the data is already contained in various documents on the vessel, but normally not electronically and normally not in one location. The Ship Safety Record is designed to provide an industry-accepted common method of identifying, maintaining, and subsequently communicating the safety-related information needed for maritime operations. It is recognized that many of the data fields are not applicable for every vessel. Appendix X1 and Appendix X2 provide examples of how data elements in this guide may be used for a specific purpose, that is, the USCG’s Automated Identification System (AIS) and the Advance Notice of Arrival.

3. Terminology

3.1 Abbreviations:
CAP—Condition Assessment Program
CFR—Code of Federal Regulations
ETA—estimated time of arrival
ETD—estimated time of departure
ILO—International Labor Organization
IMO—International Maritime Organization
IOPP—International Oil Pollution Prevention
ISM—International Management Code for the Safe Operation of Ships and for Pollution Prevention
ISM DOC—ISM Document of Compliance
ISM SMC—ISM Safety Management Certificate
MARPOL—International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol of 1978 relating thereto
NLS—noxious liquid substance
NUC—not under command
OPA 90—U.S. Oil Pollution Act of 1990
RO RO—roll-on/roll-of vessel
SOLAS—Safety of Life at Sea Convention
STCW—International Convention on Standards of Training, Certification and Watchkeeping for Seafarers 1995
UTC—universal time coordinated

4. Significance and Use

4.1 The Ship Safety Record is an electronic database of information pertaining to a specific vessel including information related to the safe operation of the vessel and the safety of its crew and the environment. The data is grouped and organized under the following key categories: vessel particulars, vessel status, crew requirements, crew status, voyage specific data, record of inspection, record of incidents, and corrective actions.

4.2 The Ship Safety Record is created and maintained in each instance for the primary benefit of the owner, technical manager, or operator who is required through the implementation of the ISM Code to be cognizant of such information. The information in the database is at all times the property of the owner who will maintain and control the dissemination of any and all of the information. It is expected that operators will elect to make portions of their Ship Safety Record database available to other interested parties such as flag states, class societies, and port states. The Ship Safety Record should provide for the implementation of several levels of electronic database security as may be required by the vessel owner or operator. The data that becomes part of the Ship Safety Record can be thought of in a number of subsets:

4.2.1 Data that is not subject to change, including particulars of the vessel, and so forth.

4.2.2 Data that is subject to change but not normally by the ship’s crew.

4.2.3 Data that will be updated periodically either manually or as a result of updates to other computer systems or applications. This would include, as an example, cargo information, ballast conditions, the names/identification of crew members, and passenger details. This would also include information relative to internal inspections, maintenance records, internal audits, safety audits, and so forth.

4.3 Guides F 1756 and F 1757 may be used as the basis for implementation of a shipboard electronic database and ship safety record.

5. Vessel Particulars

5.1 Vessel Identification:
5.1.1 IMO number.
5.1.2 Vessel name.
5.1.3 Previous names.
5.1.4 Vessel type.
5.1.5 Vessel call sign.
5.1.6 Flag state.
5.1.7 Ship owner.
5.1.8 Ship operator (who is responsible for ISM compliance).
5.1.9 Company as defined in ISM Code.
5.1.10 Company contact information.
5.1.11 Current classification society.
5.1.12 Builder’s name.
5.1.13 Construction contract date.
5.1.14 Keel laying date.
5.1.15 Delivery date.
5.2 Vessel Certificates:
5.2.1 The actual list of certificates required for a vessel is a function of the vessel’s intended trade route, flag state, and international requirements.
5.2.1.1 Certificate of registry.
5.2.1.2 Safety equipment certificate.
5.2.1.3 Safety construction certificate(s).
5.2.1.4 Cargo ship safety certificate.
5.2.1.5 Passenger ship safety certificate.
5.2.1.6 Radio safety certificate.
5.2.1.7 Cargo ship radio telegraphy certificate.
5.2.1.8 Cargo ship radio telephony certificate.
5.2.1.9 SOLAS exemption certificate.
5.2.1.10 International load line certificate.
5.2.1.11 International load line exemption certificate.
5.2.1.12 Certificate of fitness (liquefied gases in bulk).
5.2.1.13 Certificate of fitness (chemicals in bulk).
5.2.1.14 Oil pollution certificate.
5.2.1.15 Delivery date.
5.2.1.16 Minimum Safe Manning Document.
5.2.1.17 ISM Safety Management Certificate.
5.2.1.18 ISM Document of Compliance.
5.2.1.19 Classification Certificates:
5.2.1.20 International Tonnage Certificate 1969.
5.2.1.21 National Certificates:
5.2.1.22 Panama Tonnage Certificate.
5.2.1.23 Suez Tonnage Certificate.
5.2.1.24 USCG Certificate of Inspection.

13 Technical information pertaining to Port State Control is included in a Memorandum of Understanding (MOU) for various regions worldwide as listed in 2.4.
5. Stability Approval Letter.
5.2.1.22 Ship’s radio station license.
5.2.1.23 Supplementary to Safety Steering Gear Certificate.
5.2.1.24 Certificate of Sanitary Construction.
5.2.1.25 Register of Cargo Gear.
5.2.1.26 Certificate of Documentation, unless 5.2.1.1.
5.2.1.27 Life Raft Certificates.
5.2.1.28 Certificates of Financial Responsibility (COFR).
5.2.1.29 ITOPF Membership Certificate.
5.2.1.30 Certificate of Deadweight.
5.2.1.31 U.S. Tonnage Certificate.
5.2.1.32 Certificate of Official Number.

5.3 Particulars of the Vessel’s Physical Characteristics:
5.3.1 (LOA) length overall (metres/feet).
5.3.2 (LBP) Length between perpendiculars (metres/feet).
5.3.3 Design draft (metres/feet).
5.3.4 Beam (metres/feet).
5.3.5 Keel to top of mast height (metres/feet).
5.3.6 (DWT) summer deadweight (metric tons).
5.3.7 (GRT) gross register tons (metric tons) (for Tankers may be reduced GRT in accordance with IMO Res. A388(x)).
5.3.8 GRT gross register tons U.S.
5.3.9 Displacement (metric tons).
5.3.10 Lightship weight (metric tons).
5.3.11 Molded depth at sea (metres/feet).
5.3.12 Description of steering gear.
5.3.13 Type of rudder.

5.4 Particulars of the Vessel Subdivision and Stability Data:
5.4.1 (VCG) light ship vertical center of gravity (metres/feet).
5.4.2 (LCG) light ship longitudinal center of gravity (metres/feet).
5.4.3 Cargo subdivision (number of holds or tanks).
5.4.4 Intact stability limitations (cargo conditions limiting vessel operation).
5.4.5 Damage stability criteria.
5.4.6 Minimum metacentric height; G.M.
5.4.7 Identification of shipboard trim and stability electronic program.

5.5 Particulars of the Vessels Machinery:
5.5.1 Main engine type.
5.5.2 Main engine manufacturer.
5.5.3 Main engine model.
5.5.4 Main engine rating.
5.5.5 Main engine fuel.
5.5.6 List of critical auxiliary machinery.

5.6 Particulars of the Vessel Safety System:
5.6.1 Number and size of fire pumps.
5.6.2 Number and type of fire extinguishers.
5.6.3 CO₂ system/ixed fire fighting systems.
5.6.4 Number and size of life boats.
5.6.5 Number and size of life rafts.
5.6.6 Automatic fire control system.

5.7 Particulars of the Vessel Navigation Systems:
5.7.1 Description of marine radar system.
5.7.2 Description of magnetic steering compass.
5.7.3 Description of gyro compass/repeater.
5.7.4 Description of rudder angle indicator.

5.8 Particulars of the Vessel Deck Machinery:
5.8.1 Number and capacity of anchors and anchor windlass.
5.8.2 Number and capacity of mooring winch.
5.8.3 Number and capacity of cargo and other lifting gear.
5.8.4 Cargo gear registry.
5.8.5 Number and capacity of hose handling crane.

5.9 Particulars of Cargo System:
5.9.1 Type of Cargo.
5.9.2 Vessels Cargo Handling Systems—Number and size of cargo pumps, description of piping system, cargo control system, manifolds, vessels dry cargo loading and unloading systems, cargo cranes, and so forth.
5.10 Vessel Communications Systems:
5.10.1 Radio equipment.
5.10.2 Shipboard Information Technology Platform (SITP); operating system.
5.10.3 Interior communications.
5.10.4 Satcom.
5.10.5 Cellular.
5.10.6 PC network.
5.11 Vessel Response Plan(s) (Can Include International and Locally Required Plans)—Notification contact names and numbers for the following:
5.11.1 Qualified individual.
5.11.2 Oil spill response organization.
5.11.3 Spill management team.
5.11.4 Salvage/fire fighting/lightering organization.
5.11.5 Electronic hull file location/custodian.
5.12 Incident/Accident Record (Dates of Each):
5.12.1 Pollution incident.
5.12.2 Grounding.
5.12.3 Collision.

6. Vessel Status
6.1 Status of Certificates—List the current status of each certificate as stated in 5.2. The actual list of certificates required for a vessel is a function of the vessel’s trade and will be determined by flag state and international requirements.
6.1.1 Certificate of Registry.
6.1.2 Safety Equipment Certificate.
6.1.3 Safety Construction Certificate(s).
6.1.4 Cargo Ship Safety Certificate.
6.1.5 Passenger Ship Safety Certificate.
6.1.6 Safety Radio Certificate.
6.1.7 Cargo Ship Radio Telegraphy Certificate.
6.1.8 Cargo Ship Radio Telephony Certificate.
6.1.9 SOLAS Exemption Certificate.
6.1.10 International Load Line Certificate.
6.1.11 International Load Line Exemption Certificate.
6.1.12 Certificate of Fitness (liquefied gases in bulk).
6.1.13 Certificate of Fitness (chemicals in bulk).
6.1.14 Oil Pollution Certificate.
6.1.14.1 IOPP Certificate/NLS Certificate and Form A Supplement (MARPOL) and Form B.
6.1.15 Hazardous & Noxious Substances Certificate.
6.1.16 Minimum Safe Manning Document.
6.1.17 ISM Safety Management Certificate.
6.1.18 ISM Document of Compliance.
6.1.19 Classification Certificates:
   6.1.19.1 Hull.
   6.1.19.2 Machinery.
   6.1.19.3 Automation.
6.1.21 National certificates:
   6.1.21.1 Panama Tonnage Certificate.
   6.1.21.2 Suez Tonnage Certificate.
6.1.21.3 USCG Certificate of Inspection.
6.1.21.5 Stability Approval Letter.
6.1.22 Ship’s Radio Station License.
6.1.23 Supplementary to Safety Steering Gear Certificate.
6.1.24 Certificate of Sanitary Construction.
6.1.25 Register of Cargo Gear.
6.1.27 Life Raft Certificates.
6.1.29 ITOPF Membership Certificate.
6.1.30 Certificate of Deadweight.
6.1.31 U.S. Tonnage Certificate.
6.1.32 Certificate of Official Number.
6.2 Status of Hull Structure:
   6.2.1 Local structural damage reported by crew as a result of routine on-board inspection.
   6.2.2 Temporary repairs to be completed.
   6.2.3 Outstanding items from last class survey report.
   6.2.4 Status of coatings.
   6.2.5 Status of cathodic protection system.
6.3 Status of Machinery: Inoperable Equipment, Repair Work Schedules, and So Forth:
   6.3.1 Main engine.
   6.3.2 Main and auxiliary boilers.
   6.3.3 Other auxiliaries.
6.3.4 Outstanding items from last Class Survey Report.
6.4 Status of Vessel Safety Systems:
   6.4.1 inoperable equipment.
   6.4.2 last operation of emergency generator.
6.4.3 Last operation of emergency fire pump.
6.4.4 Outstanding items from last Class Survey Report.
6.5 Status of Vessel Navigation Systems:
   6.5.1 Steering gear engines.
   6.5.2 Steering control system.
   6.5.3 Marine radar system.
   6.5.4 Magnetic steering compass.
   6.5.5 Gyro compass/Repeater.
   6.5.6 Rudder angle indicator.
   6.5.7 Outstanding items from last Class Survey Report.
6.5.8 Status of Global Positioning System (GPS) receiver(s)
6.6 Report on Fuel Quality—Report the following for each fuel on board:
   6.6.1 Density.
   6.6.2 Viscosity.
6.6.3 Pour point.
   6.6.4 Water content.
   6.6.5 Fuel stability.
   6.6.6 Abrasive particles.
   6.6.7 Salt water.
   6.6.8 Strong acidity.
   6.6.9 Sulfur content.
   6.7 Report on Lube Oil Quality:
   6.7.1 Change in viscosity.
   6.7.2 Presence of water.
   6.7.3 Strong acidity.
   6.7.4 Comparative viscosity.

7. Crew Requirements

7.1 Identification of Crew Positions Consistent with Safe Manning Requirements and Master List:
   7.1.1 Master.
   7.1.2 Officers in charge of a navigational watch.
   7.1.3 Chief mate.
   7.1.4 Officer in charge of a navigational watch; near—coastal voyage.
   7.1.5 Master—near—coastal voyage.
   7.1.6 Ratings forming part of a navigational watch.
   7.1.7 Officer in charge of engineering watch propulsion power (>750 kw).
   7.1.8 Chief engineer propulsion power (>3000 kw).
   7.1.9 Chief engineer propulsion power (750 to 3000 kw).
   7.1.10 Second engineer propulsion power (>3000 kw).
   7.1.11 Second engineer propulsion power (750 to 3000 kw).
   7.1.12 Ratings forming part of an engineering watch.
   7.1.13 Radio operator.
6.1.14 GMDSS qualified officers.
   7.1.15 Officers qualified to carry out cargo transfer operations.

7.2 Training Requirements—For each position and who qualified:
   7.2.1 Requirements for familiarity with company procedures.
   7.2.2 STCW training (in accordance with Section A-VI/1 and A-VZ as applicable):
   7.2.2.1 Tanker familiarization course—chemical tanker—liquified gas tanker.
   7.2.2.2 Personal survival techniques.
   7.2.2.3 Advanced fire fighting.
   7.2.2.4 Medical first aid.
   7.2.2.5 Personnel in charge of medical care.
   7.2.2.6 Personal safety and social responsibility.
   7.2.2.7 Ro-Ros (passenger ships).
   (1) Crowd management.
   (2) Crisis management.
   7.2.3 Survival craft and rescue boat training.
   7.2.4 Fast rescue boat training.
   7.2.5 Familiarization training.
   7.2.6 Listing of officers qualified to perform on-board training and on-board assessment of training.
8. Status of Crew and Persons Other Than Passengers on Board

8.1 Identification of Crew and Persons Other Than Passengers on Board:
8.1.1 Full name of each person.
8.1.2 Rank or rating.
8.1.3 Date and place of birth.
8.1.4 Muster list assignments.
8.1.5 Position as defined in 3.1 filled by each named crew member.
8.1.6 Date signed on.
8.1.7 Vacant positions from 7.1.

8.2 Certificate of Competency for Each Crew Member as Issued by Flag State of Vessel; (Issue Date, Validity):
8.2.1 Seafarer’s name.
8.2.2 Date of birth.
8.2.3 Nationality.
8.2.4 Sex.
8.2.5 Relevant document number.
8.2.6 Date of issue.
8.2.7 Date of expiry.
8.2.8 Last revalidation date.
8.2.9 Details of dispensation(s).
8.2.10 STCW certification of each licensed crew member.
8.2.10.1 STCW competency standard (for example, regulation II/I).
8.2.10.2 Title.
8.2.10.3 Function.
8.2.10.4 Endorsements.

8.3 Training Records—For each person on board other than passengers:
8.3.1 STCW training (as applicable to type of vessel and person with designated safety or pollution duties):
8.3.1.1 Tanker familiarization course.
8.3.1.2 Personal survival techniques.
8.3.1.3 Advanced fire fighting.
8.3.1.4 Medical first aid.
8.3.1.5 Personnel in charge of medical care.
8.3.1.6 Personal safety and social responsibility.
8.3.1.7 Ro-Ros (passenger ships).
8.3.2 Familiarization training.
8.3.3 Listing of personnel by position required to have on-board training record book.
8.3.4 Evidence of training in company procedures.
8.4 Medical Records for Each Crew Member:
8.4.1 Documented evidence of medical fitness for each crew member in accordance with ILO Convention No. 73.
8.4.2 Proof of drug/alcohol testing.

8.5 Log of Hours Worked (Compliance with OPA 90 STCW)—Hours worked each week for each crew member forming part of a navigational or engineering watch.
8.6 Required Drills Last Performed (Date and Time):
8.6.1 Fire drill/explosion.
8.6.2 Boat drill.
8.6.3 Rescue boat drill.
8.6.4 Man overboard drill.
8.6.5 Entering and leaving port equipment drills.
8.6.6 Abandon ship drill.
8.6.7 Enclosed space rescue drill.

9. Voyage Specific Data
9.1 Port of Departure (Last Port of Call):
9.1.1 Name of port, country.
9.1.2 Date and time of departure.
9.2 Destination Port (Next Port of Call):
9.2.1 Name of port, country.
9.2.2 Estimated time of arrival.
9.2.3 Facility name.
9.2.4 Loading/off loading.
9.2.5 Bunkering—Y/N.
9.2.6 Lightering—Y/N.
9.2.7 Agent.
9.3 Loading Pattern:
9.3.1 Tons of cargo in each liquid cargo tank and percent full.
9.3.2 Tons of fuel in each fuel tank and percent full.
9.3.3 Tons of bulk cargo in each cargo hold.
9.3.4 Tons of bulk cargo/containers stowed above deck.
9.3.5 Planned loading and off-loading sequence.
9.3.6 Type of cargo carried.
9.3.7 Location of each cargo carried.
9.4 Ballast Condition:
9.4.1 Tons of ballast in each ballast tank; percent full and location where ballast taken on.
9.4.2 Operating draft; (propeller immersion).
9.5 Passenger Details:
9.5.1 Name and nationality.
9.5.2 Assigned cabin.
9.5.3 Assigned lifeboat.
9.6 Critical Voyage Events (Other Than 5.12):
9.6.1 Off spec bunkers.
9.6.2 Heavy weather (deviation/damage).
9.6.3 Fire on board.
9.6.4 Cargo shifts.
9.6.5 Accident/personal injury.
9.6.6 Sickness.

10. Record of Inspection
10.1 Internal Inspections:
10.1.1 Inspections of hull by crew; date, findings, and action required.
10.1.2 Inspections of machinery by crew; date, findings, and action required.
10.2 Audit Reports:
10.2.1 Shipboard audit deficiencies and corrective action taken.
10.2.2 Internal ISM audits (company management and shipboard).
10.2.3 External ICM audits (company management and shipboard).
10.2.4 Other external audit reports (company management and shipboard).
10.3 Classification Survey Records:
10.3.1 Annual hull survey.
10.3.2 Annual machinery survey.
10.3.3 Intermediate survey hull.
10.3.4 Intermediate survey machinery.
10.3.5 Special survey hull.
10.3.6 Special survey machinery.
10.4 Flag State Inspections:
10.4.1 Safety construction inspection.
10.4.2 Safety equipment inspection.
10.4.3 IOPP inspection.
10.4.4 Safety radio inspection.
10.4.5 Load line inspection.
10.5 Port State Inspections:
10.5.1 Control number.
10.5.2 Annual.
10.5.3 Reexamination.
10.5.4 Inspection for Certificate of Compliance.
10.5.5 Ballast tank examination.
10.6 CAPs and Vettings—For each type of survey, list the surveyor, date, and deficiency.
10.7 Certifying Authority ISM Audits of Operations Procedures (Dates Due/Completed, for Each):
10.7.1 Annual office audit (SMC).
10.7.2 Intermediate ship audit (DOC).
10.7.3 DOC renewal audit.

11. Record of Incidents
11.1 Port State Restrictions:
11.1.1 Prevented from entering port.
11.1.2 Cargo operation delayed pending examination.
11.1.3 Fines imposed.
11.1.4 Vessel arrested.
11.2 Unscheduled Off-Hire:
11.2.1 Equipment failure at sea.
11.2.2 Delays for ship assist/rescue.
11.2.3 Berth availability.
11.2.4 Cargo transfer restrictions.
11.2.5 External interference, for example, weather delays, acts of war, piracy.
11.3 Other Reportable Incidents:
11.3.1 Loss of propulsion.
11.3.2 Loss of electrical power.
11.3.3 Loss of steering.
11.3.4 Oil spill on-board.
11.3.5 Navigational error.
11.3.6 Near-miss incidents.

12. Corrective Actions
12.1 Scheduled Critical Maintenance:
12.1.1 By ship’s crew.
12.1.2 By shore crew.
12.1.3 By dry docking.
12.2 Awaiting Critical Equipment:
12.2.1 Equipment for vital ship’s systems.
12.2.2 Equipment for personal safety.
12.2.3 Equipment for shipboard safety systems.
12.2.4 Equipment for navigational systems.
12.3 Critical Documentation Needed:
12.3.1 Navigational information (charts, and so forth).
12.3.2 Vendor maintenance and repair manuals.
12.3.3 Required emergency notification information.
12.3.4 Updates on classification/statutory status reports.
12.4 Deficiency Log—Deficiencies not reported under other systems.

13. Keywords
13.1 Advance Notice of Arrival; ISM Code; maritime operations; port state control; ship electronic database; ship safety record

(Mandatory Information)

A1. REFERENCED STANDARDS

Standards referenced in this guide are available for purchase as follows:
ISO and IEC Standards from
American National Standards Institute (ANSI)
11 W. 42nd St.
New York, NY 10036
Tel. 212-642-3946
Fax 212-302-1286
IEEE Standards form
Institute of Electrical and Electronic Engineers
PO Box 1331
Piscataway, NJ 08855-1331
Tel 800-678-4333 (U.S. and Canada)
Tel 908-981-1393 (outside U.S. and Canada)
Fax 908-981-9667
ASTM Standards from
American Society for Testing and Materials
100 Barr Harbor Dr.
PO Box C700
West Conshohocken, PA 19428-2959
NMEA Standards from
National Marine Electronics Association
PO Box 3435
New Bern, NC 28564-3435
IMO Publications from
International Maritime Organization
4 Albert Embankment
London, U.K. SE1 7SR
United States Coast Guard Documents
Superintendent of Documents
U.S. Government Printing Office
Washington, DC 20402
APPENDIXES
(Nonmandatory Information)

X1. UNITED STATES COAST GUARD

X1.1 Automatic Identification System (AIS) View

X1.1.1 Mobile marine station identification (MMSI).
X1.1.2 Call sign, 5.1.5.
X1.1.3 Name, 5.1.2.
X1.1.4 Dimensions of ship, 5.3.1-5.3.5.
X1.1.5 Type of ship, 5.1.4.
X1.1.6 Position of fixing antenna on the ship.
X1.1.7 Ship’s position with accuracy indication.
X1.1.8 Time in UTC.
X1.1.9 Course over ground.
X1.1.10 Speed over ground.
X1.1.11 Heading.
X1.1.12 Navigational Status (for example, NUC, at anchor, and so forth)
X1.1.13 Rate of turn (where available).
X1.1.14 Angle of heel (where available).
X1.1.15 Pitch and roll (where available).
X1.1.16 Ship’s draught, 9.4.2.
X1.1.17 Hazardous cargo (type), 9.3.6.
X1.1.18 Destination, 9.2.1.
X1.1.19 ETA, 9.2.2.

X1.1.20 Short safety-related messages.

X1.2 Ship Damage Reporting to Nearest Coastal State

X1.2.1 Risk of pollution report, 5.12.1.

X1.3 Personnel Casualty Reporting to Company

X1.3.1 Report of death, injury, and serious illness, 9.6.5.
X1.3.2 Nature and cause of injury.

X1.4 Casualty Reporting to Company (Initial and Final Report for each)

X1.4.1 Collision, structural damage, grounding, stranding, fire, and explosion, 5.12.2 and 5.12.3.
X1.4.2 Machinery breakdown, damage to machinery space, and flooding, 6.3.1-6.3.3.
X1.4.3 Damage/loss to cargo.

X1.5 Oil Spill and Pollution

X1.5.1 Report to local government agencies,
X1.5.2 company,
X1.5.3 designated qualified individual, and
X1.5.4 Oil Spill Response Agency.

X2. USCG ADVANCE NOTICE OF ARRIVAL - PORT STATE CONTROL (PSC)

X2.1 The United States Coast Guard’s Advance Notice of Arrival for vessels bound for ports or places in the United States, in accordance with 33 CFR 160.207, shall include the following:

X2.1.1 The owner, agent, master, operator, or person in charge of a vessel (except a barge bound for a port or place in the United States) shall report the following at least 24 h before entering the port or place of destination to the captain of the port of destination.

X2.1.2 The Ship Safety Record (SSR) Reference Group is provided as follows to demonstrate that for vessels provided with an electronic Ship Safety Record, all the data in the Notice of Arrival has already been captured.

</table>
1. Scope

1.1 This specification covers the pipe materials and dimensions for producing non-reinforced extruded tee connections manufactured by mechanical forming processes. The term “extruded tee connection” applies to butt-weld or socket-weld connections. This specification refers to the forming process that leads to welding or brazing.

1.2 The non-reinforced extruded pipe tee connection is an alternative to the tee fittings, nozzle, and other welded connections.

1.3 The non-reinforced extruded pipe tee connection has been widely used for systems in the marine, process piping, food, pharmaceutical, and similar industries.

1.4 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 The extruded tee connection will be welded in accordance with Specification F 722. Brazing of tee connections will be in accordance with ANSI B31.5.

ISO-4200 Plain End Steel Tubes, Welded and Seamless—General Table of Dimensions and Masses Per Unit Length

3. Terminology
3.1 Definitions:
3.1.1 extruded tee connection—the tee outlet formed from the run pipe, subsequently welded or brazed to make a connection (see Fig. 1), also known in industry as a branch connection, mechanically formed tee connection, and also extruded outlet.
3.2 tee ratio—the ratio of the formed tee connection diameter, divided by the run pipe diameter as follows:

\[ \frac{D_t}{D_r} = \text{tee ratio} \]  

4. Dimensions and Tolerances
4.1 For welded connections, the dimensions and tolerances of the extruded tee connection shall be within the tolerances of the mating pipe in accordance with Specification F 722, as applicable to ANSI B31.1 and B31.3.

4.2 For braze connections, the dimensions and tolerances of the extruded tee connection shall be within the tolerances of the mating pipe in accordance with Specification F 722, as applicable to B31.5.

5. Run Pipe Materials and Limitations
5.1 Table 1 contains a list of materials that have been found to have acceptable forming qualities to produce extruded tee connections:

---

FIG. 1 Extruded Tee Connection

---

\[ \text{FIG. 1 Extruded Tee Connection} \]
The material shall be in a normalized or fully annealed condition before cold forming the extruded tee.

The steel shall be hot formed in the temperature range from 850 to 1000°C (from 1562 to 1832°F). Under these conditions, no subsequent stress relieving is required.

6. Finish, Appearance, and Repairs

6.1 The extruded tee connection shall be free from burrs and cracks, which would affect the suitability for the intended service.

6.2 Pipe/tube repairs are permitted in accordance with the applicable ASTM specification.

7. Run by Tee Connection Sizes (See Figs. 2-13)

7.1 The pipe/tube figures (Figs. 2-13) represent a matrix of the process capabilities, reflecting the extruded tee connections that can be formed from the main pipe/tube diameters and wall thicknesses.

7.2 The pipe and tube sizes and dimensions referred to in Figs. 2-13 are per ANSI B36.10M and ISO 4200. Interpolation is allowable for sizes not covered.

7.3 The limitations are based on current technology and are subject to amendment to equipment or process developments, or both.

8. Allowable Pressures and Temperatures

8.1 The allowable pressures and temperatures shall be in accordance with ANSI B31.1, B31.3, and B31.5 as applicable.

9. Keywords

9.1 extruded outlet; mechanically formed tee connections; outlets; tee connections
**NOTE 1**—Limitation shown in applicable box: \( K = K \) copper, \( L = L \) copper, and \( M = M \) copper.

**NOTE 2**—Minimum wall copper is Class DWV.

**NOTE 3**—Dimensions are nominal copper tube size (CTS) with actual OD in parentheses.

**NOTE 4**—All dimensions are in inches.

**Note 2:** All dimensions are in inches.

**FIG. 13 Extruded Tee Connection Sizes and Wall Thickness for Stainless Steel Tube (Inches)**
Standard Specification for Lap Joint Flange Pipe End Applications

This specification covers the pipe material and wall thickness applicable to lap joint flange pipe ends, manufactured by a mechanical forming process.

1. Scope

1.1 This specification covers the pipe material and wall thickness applicable to lap joint flange pipe ends, manufactured by a mechanical forming process.

1.2 The lap joint flange connection has been widely used for low-pressure systems in the marine, process piping, and similar industries.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:

A 53/A 53M Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless

A 106 Specification for Seamless Carbon Steel Pipe for High-Temperature Service

A 135 Specification for Electric-Resistance-Welded Steel Pipe

A 139 Specification for Electric-Fusion (Arc)-Welded Steel Pipe (NPS 4 and Over)

A 161 Specification for Seamless Low-Carbon and Carbon-Molybdenum Steel Still Tubes for Refinery Service

A 178/A 178M Specification for Electric-Resistance-Welded Carbon Steel and Carbon-Manganese Steel Boiler and Superheater Tubes

A 199/A 199M Specification for Seamless Cold-Drawn Intermediate Alloy-Steel Heat-Exchanger and Condenser Tubes

A 200 Specification for Seamless Intermediate Alloy-Steel Still Tubes for Refinery Service

A 209/A209M Specification for Seamless Carbon-Molybdenum Alloy-Steel Boiler and Superheater Tubes

A 210/A 210M Specification for Seamless Medium-Carbon Steel Boiler and Superheater Tubes

A 250/A 250M Specification for Electric-Resistance-Welded Ferritic Alloy-Steel Boiler and Superheater Tubes

A 252 Specification for Welded and Seamless Steel Pipe Piles

A 312/A 312M Specification for Seamless and Welded Austenitic Stainless Steel Pipes

A 333/A 333M Specification for Seamless and Welded Steel Pipe for Low-Temperature Service

A 334/A 334M Specification for Seamless and Welded Carbon and Alloy-Steel Tubes for Low-Temperature Service

A 500 Specification for Cold-Formed Welded and Seamless Carbon-Steel Structural Tubing in Rounds and Shapes

A 512 Specification for Cold-Drawn Butt weld Carbon-Steel Mechanical Tubing

A 519 Specification for Seamless Carbon and Alloy Steel Mechanical Tubing

A 587 Specification for Electric-Resistance-Welded Low-Carbon Steel Pipe for the Chemical Industry

A 589 Specification for Seamless and Welded Carbon-Steel Water-Well Pipe

A 672 Specification for Electric-Fusion-Welded Steel Pipe for High-Pressure Service at Moderate Temperatures

B 42 Specification for Seamless Copper Pipe, Standard Sizes

B 88 Specification for Seamless Copper Water Tube

B 88M Specification for Seamless Copper Water Tube [Metric]

B 280 Specification for Seamless Copper Tube for Air Conditioning and Refrigeration Field Service

B 337 Specification for Seamless and Welded Titanium and Titanium Alloy Pipe

B 338 Specification for Seamless and Welded Titanium and Titanium Alloy Tubes for Condensers and Heat Exchangers

B 466/B 466M Specification for Seamless Copper-Nickel Pipe and Tube

B 467 Specification for Welded Copper-Nickel Pipe

2.2 ANSI Standards:

B31.1 Power Piping

B31.3 Chemical Plant and Petroleum Refining Piping

1 This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.11 on Machinery and Piping Systems.

4 Annual Book of ASTM Standards, Vol 02.01.

7 Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.
B16.5 Pipe Flanges and Flanged Fittings

B16.9 Factory-Made Wrought Steel Butt-Welding Fittings

B16.24 Cast Copper Alloy Pipe Flanges and Flanged Fittings: Class 150, 300, 400, 600, 900, 1500, and 2500

B16.42 Ductile Iron Pipe Flanges and Flanged Fittings, Classes 150 and 300

2.3 ISO Standard:

ISO-7005-1 Metallic Flanges Part 1: Steel Flanges

ISO-7005-2 Metallic Flanges Part 2: Cast Iron Flanges

ISO-7005-3 Metallic Flanges Part 3: Copper Alloy and Composite Flanges

3. Terminology

3.1 back-up flange—the flange used to back up the lap joint to facilitate the pipe connection, also known in industry as loose, slip, plate, or spin flange.

3.2 convoluted flange—a back-up flange designed with a variable cross section to provide the material in the stress-related zones.

3.3 lap joint end—the formed pipe end to accommodate the back-up flange, commonly referred to as a Van Stone flange (see Fig. 1).

4. Dimensions and Tolerances

4.1 The lap joint end outside diameter shall be formed to the raised face flange diameter as covered under ISO Standard 7005-1, 7005-2, 7005-3, and ANSI B16.9 Table 7, Dim. G.

4.2 The back-up flange dimensions are covered under ANSI Standards B16.5, B16.24, and B16.42, and ISO Standards 7005-1, 7005-2, and 7005-3.

5. Fabrication

5.1 The formed lap joint end may have a smooth or serrated face.

5.2 The back-up flange may be a different material from the lap joint end pipe as long as it conforms to the applicable piping system codes or standards.

5.3 Convoluted back-up flanges may be used if they comply with the applicable piping system codes or standards.

6. Pipe Materials and Limitations

6.1 Table 1 contains a list of materials that have been found to have acceptable forming qualities to produce a lap joint end.

7. Finish, Appearance and Repairs

7.1 The lap joint flange pipe connection shall be produced in accordance with accepted shop practices and shall be free from burrs and cracks, which would affect the suitability for the intended service.

7.2 Pipe/tube repairs are permitted in accordance with the applicable ASTM specification.

Fine print:

a Titanium run pipe must be commercially pure (99.1 %).

b Steel shall be hot formed in the temperature range from 850 to 1000°C (from 1562 to 1832°F). Under these conditions, no subsequent stress relieving is required.
8. Dimensional Limitations (see Tables 2-4)

8.1 Interpolation is allowable for sizes not covered.
8.2 The limitations are based on current technology subject to amendment to equipment or process developments, or both.

<sup>a</sup>For copper-nickel, nearest pipe class to maximum pipe wall is Class 200.
Standard Practice for Establishing Shipbuilding Quality Requirements for Hull Structure, Outfitting, and Coatings

1. Scope
   1.1 This practice consists of three annexes: hull structure, outfitting, and coating. The subject of these annexes was selected for several reasons. Other commercial shipbuilding nations already have in place widely recognized standards of expectations in these areas. These constitute the most significant areas where workmanship is a critical factor in customer satisfaction. The cost associated with the labor involved in these three areas is a significant factor in construction man-hours and overall schedules.

   1.2 The standard criteria provided in this practice are intended to apply to conventional, commercial ship construction. In many cases, specialized, nonconventional vessels using nonstandard materials or built-to-serve sole requirements may require unique acceptance criteria that are beyond those provided in this practice.

2. Referenced Documents
   2.1 ASTM Standards:
      D 4417 Test Methods for Field Measurement of Surface Profile of Blast-Cleaned Steel
      E 337 Test Method for Measuring Humidity with a Psychrometer (the Measurement of Wet-Bulb and Dry-Bulb Temperatures)

   2.2 ISO Standards:
      ISO 8502–3 Assessment of Dust on Steel Surfaces Prepared for Painting (Pressure-Sensitive Tape Method)
      ISO 8502–6 Extraction of Soluble Contaminants for Analysis—The Bresle Method

   2.3 NACE Standards:
      NACE No. 5 Surface Preparation and Cleaning of Steel and Other Hard Materials by High-and Ultrahigh-Pressure Water Jetting Prior to Re-coating (SSPC-SP 12)
      NACE No. 7 Interim Guide and Visual Reference Photographs for Steel Cleaned by Water Jetting (SSPC-VIS 4(1))

   2.4 SSPC Standards:
      SSPC-AB 1 Mineral and Slag Abrasives
      SSPC-AB 2 Specification for Cleanliness of Recycled Ferrous Metallic Abrasives
      SSPC-PA 2 Measurement of Dry Coating Thickness With Magnetic Gages
      SSPC-SP 1 Solvent Cleaning
      SSPC-SP 2 Hand Tool Cleaning
      SSPC-SP 3 Power Tool Cleaning
      SSPC-SP 7 Brush-Off Blast Cleaning
      SSPC-SP 10 Near-White Blast Cleaning
      SSPC-SP 11 Power Toll Cleaning to Bare Metal
      SSPC-SP 12 Surface Preparation and Cleaning of Steel and Other Hard Materials by High-and Ultrahigh-Pressure Water Jetting Prior to Re-coating (NACE No. 5)
      SSPC-VIS 1-89 Visual Standard for Abrasive Blast Cleaned Steel
      SSPC-VIS 3 Visual Standard for Power- and Hand-Tool Cleaned Steel
      SSPC-VIS 4(1) Interim Guide and Visual Reference Photographs for Steel Cleaned by Water Jetting (NACE No. 7)

   2.5 NSRP Documents:

3. Summary of Practice
   3.1 This practice provides workmanship criteria to be applied to commercial shipbuilding or ship repair, or both. The criteria covers three primary phases of ship construction, that is, hull structure, outfitting, and coatings. Specific criteria to be applied to these phases are covered in the three annexes prior to publication of this practice.
selected from this standard should be as contractually agreed between the ship owner and shipbuilder.

4. Significance and Use

4.1 To achieve success in ship construction, it is necessary for the ship owner and the ship builder to agree on the level of quality in the final product. Classification rules, regulatory requirements, and ship specifications all help to define an acceptable level of construction quality; however, this guidance alone is not sufficient. It is up to the shipbuilder, therefore, to describe the level of workmanship sufficiently that will be reflected in the delivered ship, and for the ship owner to communicate his expectations effectively for the final product.

4.2 It is the intent of this document to contribute to these objectives in the following ways:

4.2.1 To describe a reasonable acceptable level of workmanship for commercial vessels built in the United States.

4.2.2 To provide a baseline from which individual shipyards can begin to develop their own product and process standards in accordance with generally accepted practice in the commercial marine industry.

4.2.3 To provide a foundation for negotiations between the shipbuilder and the ship owner in reaching a common expectation of construction quality.

4.3 The acceptance criteria herein are based on currently practiced levels of quality generally achieved by leading international commercial shipbuilders. These criteria are not intended to be a hard standard with which all U.S. shipyards must comply. Rather, they are intended to provide guidance and recommendations in the key areas that play a major role in customer satisfaction and cost-effective ship construction.

5. Keywords

5.1 coatings; hull structure; outfitting; quality; shipbuilding; workmanship

### Fitting Accuracy

#### Gap before Welding

- Parts requiring good appearance:
  - Outside surface of shell plates, Exposed deck, Exposed superstructure
  - Grind flush
  - See Annex A3 for surfaces that are to be painted

- Parts not requiring good appearance:
  - Inside of tank, Inside of ceiling, Deck to be shield with deck composition etc.
  - Grind only conspicuous parts finishing
  - See Annex A3 for surfaces that are to be painted

### Surface defect

- Scar:
  - Depth (d) ≤ 10a
  - Length (a) ≤ 10
  - d ≤ 0.8
  - a ≤ 1.0
  - a ≤ 1.0

## I. HULL OUTFITTING

### Division

I-A WATER TIGHT STEEL HATCH COVER

### Section

1. HATCH COVER (SINGLE PULL TYPE)

#### Sub-section

4. Intermediate hinge and water tightness

#### Item

- Height from base line to packing gutter
- Breadth of packing gutter
- Deviation between compression bar and packing
- Compressed depth of packing
- Deviation between top plates
- Deviation between side plates
- Clearance between hatch covers

#### Figure

![Diagram](image)

#### Standard Range (mm)

- 6
- 6.7
- 6.8
- 6.9
- 6.19
- 6.2
- 6.2
- 6.23

#### Tolerance Limits (mm)

- ±1
- ±1
- ±1
- ±5
- ±2
- ±2
- ±2
- ±3
- 0
- -5 ± 10

#### Remarks

- ±thickness of compression bar
- Compressed depth of packing surrounding hatch cover to be in accordance with this item.
- * not defined

#### 5. Installing position of snap for quick acting cleat

- Longitudinal deviation
- Vertical deviation

#### Figure

![Diagram](image)

#### Standard Range (mm)

- 6.24
- 6.25

#### Tolerance Limits (mm)

- ±4
- ±4

#### Remarks

- Refer to note

#### 6. Clearance between hatch cover and hatch coaming

- Touchpiece type
- Directly of touched type
- Rest pad type

#### Figure

![Diagram](image)

#### Standard Range (mm)

- 6.26
- 6.27
- 6.28

#### Tolerance Limits (mm)

- ±1
- ±3
- ±1

#### Remarks

- Refer to note

---

**Note**

Every touchpiece of A or C type to be in touch with end and side girder of hatch cover or rest are of hatch cover.

For type B, end and side girder of hatch cover to be in touch with the coaming top plate at least one position in any 3 meters.

### Section

2. HATCH COVER (SINGLE PULL TYPE)

#### 1. Dimension of hatch coaming

- Length
- Breadth
- Difference between diagonals

#### Figure

![Diagram](image)

#### Standard Range (mm)

- 6.1
- 6.2

#### Tolerance Limits (mm)

- ±5
- ±5
- ±10
- ±10
- ±15

#### Remarks

- * to be in accordance with hull specification.
- L = designed dimension
- L = actual dimension

---

### A3.2 Introduction

A3.2.1 This practice for coatings addresses those aspects of coating application inherent in achieving finished product quality that can be measured and warranted as meeting acceptable criteria. Because of the nature of coating systems, in which preparation and methodology directly affect finished quality, this practice contains information about processes and application practices, as well as, pass/fail criteria of the end product. It should be acknowledged that measuring finished coating attributes cannot determine that good application practices were followed and, therefore, cannot be used as a sole means of warranting the finished quality of the coating.

| 34  | “Sagging” | The “sagging” of the film needs repair due to the following causes:  
(1) Spray dust, dust, etc. tend to collect.  
(2) Sag having a large film thickness. Solvent tends to collect on high film thicknesses.  
If coating is applied over the “sagging” area, solvent evaporation becomes more difficult  
leading to possible cracks in the film.  
“Sagging” to be repaired is as follows:  
(a) Sagging with the height of 2mm and more.  
(b) Wide “sagging”  
(c) “Sagging” in the bottom corners |

FIG. A3.13 Coating Repair Standards (Explanations)
<table>
<thead>
<tr>
<th>No.</th>
<th>Item</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| 36  | Foreign matter | When abrasives are used in surface preparations (blasting), abrasives remaining may adhere to the substrate and be trapped in the film during painting.  
Foreign material shall be removed by screen, sanding, etc. as directed by the paint manufacturer. |
| 37  | Craters, pinholes, and bubbles | (1) Pinholes tend to occur at the pit of manual welding bead.  
(2) Craters tend to occur when surface tension becomes uneven during the film drying process. A crater is a concave, and reduces film thickness.  
(3) Bubbles occur when paint mixed with air is applied in the airless painting.  
Repairs to coating to be in accordance with manufacturer recommendations. Generally, surface will be feathered by sanding or screening and coating applied to achieve desired DFT. |
| 38  | "Blushing" | The film will "blush", due to humidity absorbed by the hardening agent. When humidity rises or dew is produced before curing, this may occur. Blushing is confined to the film surface and does not affect film performance. However, excessive blushing must be repaired because it hinders adhesion of overcoating. |
| 39  | Mechanical damage | The surface of the film shall be lightly abraded with sandpaper, screen, or as recommended by coating manufacturer and coating applied to the desired DFT.  
Feather |

FIG. A3.14 Film Thickness Measurement Standards (Explanations)
<table>
<thead>
<tr>
<th>No.</th>
<th>Item</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| 44  | Temperature (During painting and drying) | (1) Lowest temperature  
   (a) Temperature must be 3°C or more above the dew point. Theoretically the steel plate surface temperature is used. However the air temperature in tank is practically used herein.  
   (b) Curing of epoxy resin slows down when the temperature drops below 10°C and 5°C is the lowest limit. It is preferable to keep the temperature above 10°C and in conformance with the paint manufacturer’s recommendation.  
   (2) Highest temperature  
   The maximum temperature is affected by the type of paint used and the painting process. Consult the paint manufacturer for maximum allowable temperature for application and cure. |
| 45  | Humidity (During painting, and initial drying) | Relative humidity is to be below 85%. This value applies when the painted surface temperature is equal to or above the atmospheric temperature. |
| 46  | Ventilation | (1) The amount of ventilation required during painting and drying is greater than that required for blasting due to the following reasons:  
   (a) The film begins hardening with evaporation of solvents in the film.  
   (b) Solvent evaporation is greatly influenced by ventilation and temperature.  
   (c) Retained solvents affect film performance.  
   (2) Air change rate  
   This standard is determined for correct film performance and this varies depending on tank capacity. These standards are different from OSHA 29 CFR 1915 35 and OSHA 29 CFR 1926.57. Consult “Industrial Ventilation, 20th Edition” and OSHA Technical Manual Section III: Chapter 3 for guidance.  
   (3) Air change rate for high humidity (85% RH or above). With high humidity, dew must be prevented after painting, from blasting stages up to the film hardening stages. Otherwise, the following may occur:  
   (a) Turning of blasted surfaces  
   (b) Film defects (Blushing, poor adhesion)  
   As described above in (1) insufficient ventilation also deteriorates film performance. Consequently it is preferable to ventilate at least three times per hour even with high humidity for two days (this varies according to the type of paint) immediately after painting. |

FIG. A3.15 Environmental Painting Standards (Explanations)
<table>
<thead>
<tr>
<th>No.</th>
<th>Item</th>
<th>Explanation</th>

</thead>
</table>
| 46 47 | The safety and Health Standards for Painting | (1) The safety and Health Standards for Painting  
(a) When gas concentration reaches 10% of the lower explosion limit (LEL), stop operations and evacuate workers.  
(b) When gas concentration exceeds 10% of the lower explosion limit (LEL), take appropriate measures such as adding fans and reducing the number of paint sprayers. Refer to OSHA 29 CFR 1915.35 and 29 CFR 1926.57 Consult "Industrial Ventilation, 20th Edition" 1 OSHA Technical Manual Section III: Chapter 3 for guidance. |
| 45 46 47 | Instruments for measuring environmental conditions | (1) For humidity and dew point:  
Sling psychrometer and psychrometric tables or battery operated psychrometer according to ASTM E 337 Standard.  
(2) Surface temperature  
Magnetic contact surface thermometer.  
(3) Anemometer  
Used to measure the ventilation volume and rate. |
| 48 49 | Erection of scaffoldings | (1) Scaffolding pieces  
Scaffolding pieces not to be removed are recommended to be of stainless steel.  
(2) The distance between painted surfaces and scaffolding is to be between 150 and 300 mm (to prevent unpainted portions).  
(3) Scaffold planks of expanded metal or similar open design to assist in abrasive removal and ventilation.  
(4) Height of scaffolding; 1,700 to 1,900 mm (to ensure easy and satisfactory work). |
| 50 | Illumination | Explosion-proof lighting is to be used during painting and drying. |

FIG. A3.15 (continued)
Standard Guide for
Database Structure of Electronic Data Interchange Between
Ship Owner and Shipyard for Contract Administration\(^1\)

This standard is issued under the fixed designation F 2017; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This standard provides the database structure of electronic data interchange (EDI) information between ship owner and a shipyard for contract administration. Ship owners (hereinafter referred to as owners) and shipyards may each have unique software programs to manage their respective portions of a ship repair period. There is information that must be exchanged between the parties during the contract period. This standard has been developed to establish common field lengths, names, and types such that the exchanged information can be used directly by the respective software programs without scanning, typing, or redundant keying of information.

2. Terminology
2.1 Definitions of Terms Specific to This Standard:
2.1.1 BLOB—short for binary large object, a collection of binary data stored as a single entity in a database management systems (DBMS). BLOBs are used primarily to hold multimedia objects such as images, videos, and sound, though they can also be used to store programs or even fragments of code. Not all DBMSs support BLOBs.

2.1.2 CHAR(XX)—character data, alphanumeric where XX represents the maximum number of characters permitted and SQL fills the remaining spaces with blanks if fewer than the maximum are entered.

2.1.3 Condition Found Report (CFR)—a report generated by the shipyard to inform the owner of conditions found, deficiencies with the specification, or any other pertinent information regarding a particular work item.

2.1.4 Condition Found Report Response—the owner’s response back to the shipyard’s Condition Found Report. It may be a simple acknowledgement of receipt or a lengthy response and reference to a Request for Proposal.

2.1.5 DATE—stores the year, month, and day values of a date. The length of a DATE is ten positions, as in 01/31/2000 (for 31 Jan 2000).

2.1.6 INTEGER—a number that has no fractional part and its precision (maximum number of digits) depends on the specific SQL implementation.

2.1.7 owner—in this case, the recognized authority for contracting ship repair work.

2.1.8 Request for Proposal—an owner-generated document asking the shipyard to add, modify, or delete work to the existing package. It may or may not be related to a shipyard initiated CFR.

2.1.9 shipyard—in this case, the principal party to a contract with a ship owner.

2.1.10 SQL compliant—an industry standard data sublanguage, specifically designed to create, manipulate, and control relational databases. SQL-92 is the latest version of the standard.

2.1.11 tests and trial agenda—the agenda provided by the shipyard, which details the planning schedule for all testing events to be conducted during a dock or sea trial.

3. Significance and Use
3.1 Intended Use—Compliance with this practice will allow the sharing of electronic data between contracting parties that is normally done by hard copy. This can only be used when both parties use a database-derived software package to manage their contracts. Specifically, it will:

3.1.1 Eliminate the duplication of manual entry of data into each party’s contract administration software package and
3.1.2 Allow for wide access of the data to all authorized parties.

4. Database Structure
4.1 A shipyard contract management database, or an owner contract management database, may contain hundreds of tables and fields and thousands of records. Much of the data is business-sensitive and must remain under the control of the party. However, there is data that is shared and common to both parties in a ship repair contract.

4.2 Condition Found Report—A Condition Found Report, generated by the shipyard and forwarded to the owner, will be structured as follows:
4.3 **Condition Found Report Response**—A Condition Found Report Response, generated by the owner and forwarded to the shipyard, will be structured as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Required Field</th>
<th>Type</th>
<th>Size</th>
<th>Data Element</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>Condition Found Report ID</td>
<td>Y</td>
<td>CHAR</td>
<td>10</td>
<td>shipyard</td>
<td></td>
</tr>
<tr>
<td>Contract number</td>
<td>Y</td>
<td>CHAR</td>
<td>16</td>
<td>owner</td>
<td></td>
</tr>
<tr>
<td>Work item number</td>

</tr>
<tr>
<td>Shipyard proposal</td>
<td>N</td>
<td>Currency</td>
<td>$M</td>
<td>shipyard</td>
<td></td>
</tr>
</tbody>
</table>

4.6 **Test and Trial Agenda**—A TTA, generated by the shipyard and forwarded to the owner, will be structured as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Required Field</th>
<th>Type</th>
<th>Size</th>
<th>Data Element</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTA ID</td>
<td>Number (Long)</td>
<td>4</td>
<td></td>
<td></td>
<td>owner</td>
</tr>
<tr>
<td>Owner contract number</td>
<td>Y</td>
<td>CHAR</td>
<td>16</td>
<td>owner</td>
<td></td>
</tr>
<tr>
<td>Shipyard contract number</td>
<td>Y</td>
<td>CHAR</td>
<td>16</td>
<td>shipyard</td>
<td></td>
</tr>
<tr>
<td>Ship name</td>
<td>N</td>
<td>CHAR</td>
<td>30</td>
<td>owner</td>
<td></td>
</tr>
<tr>
<td>Agenda date</td>
<td>Y</td>
<td>DATE</td>
<td>(MM/DD/YYYY)</td>
<td>shipyard</td>
<td></td>
</tr>
<tr>
<td>Shipyard POC</td>

Standard Guide for the Basic Elements of a Shipboard Occupational Health and Safety Program

1. Scope

1.1 This guide covers the basic elements of a Shipboard Occupational Health and Safety Program (SOHSP). These elements are applicable to all vessel types including but not limited to tank vessels, dry bulk carriers, passenger vessels, roll-on roll-off vessels, ore bulk oilers, offshore supply vessels, tugboats, towboats, and barges. The elements described are fundamental pieces of a systematic occupational safety and health program and may be used by company line managers, health and safety personnel or consultants who are implementing, improving, or auditing the effectiveness of a shipboard health and safety program.

1.2 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ANSI Standards:
- ANSI Z41-1991 Personal Protection – Protective Footwear
- ANSI Z87.1-1989 Practice for Occupational and Educational Eye and Face Protection
- ANSI Z88.2-1992 Respiratory Protection
- ANSI Z89.1-1986 Protective Headwear for Industrial Workers
- ANSI Z244.1-1982 (R1993) Safety Requirements for the Lock Out/Tag Out of Energy Sources
- ANSI/ASA S3.44-1996 Determination of Occupational Noise Exposure and Estimation of Noise-Induced Hearing Impairment
- ANSI/AWS Z49.1-1994 Safety in Welding, Cutting and Allied Processes

2.2 Other Documents:
- NFPA 306-1997 Control of Gas Hazards on Vessels
- NFPA 1991-2000: Vapor Protective Suits for Hazardous Chemical Emergencies
- IMO A.468(XII) Code on Noise Levels Onboard Ships
- IMO A.849 (20) Code for Investigation of Marine Casualties and Incidents
- IMO A.864 (20) Recommendations for Entering Enclosed Spaces Aboard Ships
- 46 CFR 16.210 Pre-employment Testing Requirements
- U.S. Coast Guard Navigation and Vessel Inspection Circular 2–98 Physical Evaluation Guidelines for Merchant Mariner’s Documents and Licenses

3. Significance and Use

3.1 This guide does not set specific performance or technical criteria, but recommends that companies set policies and objectives and develop procedures for managing their health and safety program. Companies should consider their unique organization, culture, and hazards on their vessels and the possible effects of their operations. The elements are intentionally flexible and may be tailored to address any size of operation or any vessel type. Note that although the standard is aimed at the shipboard occupational health and safety program, some of the elements address activities and commitments that must be completed or made by shore side personnel (for example, executive management commitment and provision of adequate resources). Key to the effectiveness of the program is the implementation of each element within an interconnected system.

4. Basic Elements

4.1 Executive Management Commitment and Leadership—Executive management commitment and leadership is a precondition for an effective SOHSP. Executive management
commitment and leadership includes, but is not limited to integrating health and safety into the management structure and fabric of the company, developing a health and safety policy, developing health and safety objectives, providing resources to achieve the objectives, defining stewardship responsibilities and providing authority to carry out those responsibilities, and establishing accountability for safety and health as a part of job performance reviews. Further guidance is provided in Annex A1.

4.2 Employee Participation—Employees from all levels including crewmembers, officers, masters, persons in charge, and shoreside personnel should be directly involved with the SOHSP. Shipboard and shoreside employees should be involved in developing, implementing, evaluating, and modifying the SOHSP. Employees should also participate in setting health and safety objectives and performance criteria. This involvement might be through employee membership on safety committees that provide input to management for the development of safety and health policy, debate and set health and safety goals, measure and evaluate performance, and recommend modifications to the program based on their evaluation. Shoreside and shipboard employees should work together to achieve safety and health goals. For example, shoreside personnel should participate on vessel safety committees since their decisions affect vessel operations and ultimately the health and safety of vessel personnel. In large companies, individual vessel safety committees might submit recommendations to an overarching safety committee that evaluates the recommendations and sets policy to apply appropriate recommendations to the entire fleet. Further guidance is provided in Annex A2.

4.3 Hazard Anticipation, Identification, Evaluation and Control—The core function of any health and safety program is prevention. Health and safety hazards including fire, reactivity, and chemical and physical hazards, need to be anticipated and prevented from occurring. Hazards and unsafe operating procedures need to be identified and addressed so they will not endanger employees or the public and will not damage the vessel, cargo, or third party property. Potential hazards should be systematically anticipated, identified, evaluated, and controlled. Tools such as job hazard analysis, industrial hygiene exposure assessments, and risk assessment/management methodologies enable the evaluation and control of hazards. Further guidance is provided in Annex A3.

4.4 Training—Employees should receive training appropriate for their duties and responsibilities so that they may work safely and not endanger their shipmates or the public. In addition, employees who have specific health and safety responsibilities (generally supervisors with responsibility for the safety of others, but also nonsupervisors who are assigned to safety committees or as crew member representatives) should receive training to enable them to carry out their health and safety program responsibilities. Further guidance is provided in Annex A4.

4.5 Record Keeping—Company records sufficient to demonstrate the effectiveness of the health and safety program should be maintained. Data that enables trend or pattern analysis for root causes is particularly desirable. For example, results of audits that evaluate effectiveness of the safety and health management system should be maintained. Records that indicate industrial hygiene exposure assessments have been conducted and appropriate controls have been implemented should be maintained. Current job safety analyses and corresponding standard operating procedures with safe work practices should be documented. Injury and illness data should be maintained to enable the identification of trends and patterns that associate the injury or illness with a common cause, which can be addressed. Training topics, lesson outlines, and attendees should be documented. Where appropriate, such records should permit evaluation of the program on individual vessels as well as across an entire fleet. Further guidance is provided in Annex A5.

4.6 Contract or Third Party Personnel—When contract or third party personnel are on board to perform work, vessel personnel should provide information regarding potential hazards on the vessel that may affect the contract or third party personnel. Potential hazards related to the work conducted by contract or third party personnel should be provided to the vessel owner/operator and/or the master/person in charge. Each employer should provide appropriate information regarding vessel and work hazards to their own employees. For example, exchange of information on chemical hazards might be accomplished by exchanging appropriate material safety data sheets (MSDS), then each employer can inform their own employees of the hazards identified in the MSDS. Further guidance is provided in Annex A6.

4.7 Fatality, Injury, Illness, and Incident Investigation—Personnel injuries, occupational illnesses, and “near miss” incidents should be promptly investigated. The current incident and other similar occurrences should be analyzed to identify the primary (root) cause and any contributing factors. The investigation report, setting forth primary cause, contributing factors, and corrective measures should be presented to management. Followup action that specifically addresses the report’s recommendations for corrective action should be undertaken and documented. Further guidance is provided in Annex A7.

4.8 Systematic Program Evaluation and Continuous Improvement—Maintaining an effective health and safety program is an ongoing process. The SOHSP should have systems for detecting, reporting, and correcting nonconformities to the program. Some type of “formalized” evaluation should also be conducted on a periodic basis consistent with other aspects of the vessel’s management plan. The evaluation should determine whether the SOHSP is appropriate for the vessel and its operations, that actual practices are consistent with the programs and procedures in the SOHSP, and that the SOHSP is effective. Comparison of data and records (refer to Annex A5, Record Keeping) to performance objectives and criteria (refer to Annex A1, Section A1.3, health and safety objectives) can provide important indicators of the effectiveness of the SOHSP. Further guidance is provided in Annex A8.

5. Keywords

5.1 health; safety
A1. MANAGEMENT COMMITMENT AND LEADERSHIP

A1.1 Health and safety programs are most effective when they are integrated into the management structure of a company, rather than treated as an “add on” program. Examples of integrated health and safety efforts include:

A1.1.1 Developing Standard Operating Procedures (SOPs), written to the education level of the person who must follow the SOP, that integrate safe work practices and basic operational functions,

A1.1.2 Making design review by qualified health and safety personnel an element of the acquisition procedures, and

A1.1.3 Making consultation with qualified health and safety personnel a part of the process when making changes to operations.

A1.2 Executive management sets the tone for the entire SOHSP through their policy regarding health and safety. Examples of values that can be stated and commitments that can be made in company policy include:

A1.2.1 A statement that the company will make every effort to provide a safe and healthy workplace and that working safely is a condition of employment,

A1.2.2 Statements that convey how important each crew member is to the vessel as a fellow worker and as a company resource:

A1.2.2.1 “The basic safety policy of this company is that no task is so important that an employee must violate a safety rule or put himself or herself at risk of injury or illness in order to get it done.”,

A1.2.3 A written commitment to provide resources necessary to implement the health and safety program could also be included in the policy statement, and

A1.2.4 Management can demonstrate commitment to the safety and health policies through word and action. For example, managers visiting vessels should follow safety rules and standard operating procedures, including use of hearing protection, safety glasses, safety shoes, protective clothing, and so forth.

A1.3 Setting and attaining health and safety objectives demonstrates a company’s commitment to improvement of health and safety performance. Objectives provide a target against which those who are responsible for health and safety may measure their progress. Quantifiable objectives are desirable since often, “What gets measured gets done.” (Refer to Annex A8, Systematic Program Evaluation, for examples of performance measures and an overall program audit.) Health and safety objectives may include:

A1.3.1 Eliminate lost time incidents,

A1.3.2 Report “near miss” incidents or problems, evaluate, and if appropriate, implement changes to prevent a more serious incident or accident in the future,

A1.3.3 Develop and implement a program of evaluations through drills and other means (for example, simulators) to ensure that personnel are competent to carry out their duties,

A1.3.5 Complete periodic comprehensive (or area-specific) hazard review.

A1.3.6 Reduce exposure levels to airborne vapors to acceptable levels through appropriate controls,

A1.3.7 Complete annual respiratory fit testing on schedule,

A1.3.8 Develop and implement acute toxic exposure procedures addressing first aid procedures, obtaining additional emergency medical assistance, and appropriate medical surveillance tests (for example, S-phenylmercapturic acid in urine following a potential benzene overexposure), and

A1.3.9 Develop and implement an occupational health medical surveillance plan.

Note A1.1—The intent of this medical surveillance plan is to ensure employees are not overexposed to hazards on the job including chemicals, radiation, noise, and so forth. This section is not intended to address requirements of the Americans with Disabilities Act or issues covered by physical standards related to watch keeping published elsewhere.

A1.4 Company management holds the authority to dedicate necessary resources to achieve health and safety objectives. Necessary resources may include:

A1.4.1 Access to health and safety information,

A1.4.2 Training, including classroom and on-the-job training, that cover topics identified by the company’s risk assessment process as well as those required by international or national standards. These topics would include but not be limited to existing chemical and mechanical hazards,

A1.4.3 Qualified health and safety professionals, either on the company staff or hired as consultants,

A1.4.4 Capital investments in engineering controls, and

A1.4.5 Personal protective equipment.

A1.5 Defining stewardship responsibilities and providing authority to carry out those responsibilities is an essential component of management commitment. For example:

A1.5.1 Company Management Should:
A1.5.1.1 Designate a shoreside person who has access to the executive management of the company and is responsible to ensure essential health and safety issues are clearly communicated to executive management of the company and decisions regarding those issues are clearly communicated back to the vessel.
A1.5.1.2 Ensure adequate resources of time, funds for health and safety equipment, training and expertise are available to effectively implement the program throughout the company.
A1.5.1.3 Ensure that a safety committee or other mechanism to involve crewmembers in health and safety issues is created on each vessel adequately.
A1.5.1.4 Ensure that the elements of the shipboard health and safety program are integrated and systematically implemented throughout the company and on each vessel.
A1.5.1.5 Ensure that objectives are developed and performance measures are reported from each vessel.
A1.5.1.6 Ensure that all appropriate programs are developed and implemented including, but not limited to respiratory protection, hearing protection, confined space entry, and lock out-tag out.
A1.5.1.7 Set a good example for employees by following established safety rules on vessels and by staying current on training commensurate with duties.
A1.5.1.8 Report unsafe practices or conditions observed while on a vessel to the supervisor of the area.
A1.5.2 Master/Person-In-Charge/Operator Should:
A1.5.2.1 Ensure each crewmember receives an initial vessel orientation, covering company safety policy, emergency procedures, access and egress, fire fighting, job hazards, and information on hazardous materials before beginning work. Document the completion of this orientation.
A1.5.2.2 Ensure each crewmember is competent to perform a task or job by requiring a prejob explanation and/or walk through of all procedures including safe work practices before starting work on that project or equipment. Require prejob refresher training if the employee cannot demonstrate this competence.
A1.5.2.3 Ensure each crewmember has been issued and received training on the use of required personal protective equipment (PPE) before starting work on a project requiring PPE.
A1.5.2.4 Complete periodic walk-around health and safety checks of the vessel (accompanied by appropriate personnel including those who have responsibilities or work in certain areas, for example, chief engineer and an oiler in engine spaces and first mate and able-bodied seaman on deck).
A1.5.2.5 Periodically observe work performance of employees for compliance with safety rules contained or documented in the SOHSP.
A1.5.2.6 Set a good example for subordinates by following established safety rules and attending training as appropriate.
A1.5.2.7 Complete a preliminary investigation of all accidents and report findings to company management.
A1.5.2.8 Provide information to company management suggesting changes to company-wide standard operating procedures or equipment that will improve employee safety.
A1.5.3 Officers/Other Management Personnel Should:
A1.5.3.1 Act as the master’s or person-in-charge’s representative and implement examples listed for the master in areas over which they exercise supervision (for example, first mate responsible for “deck” personnel and Chief Engineer responsible for “engineers”).
A1.5.4 Management should establish accountability for health and safety as part of job performance reviews. Performance reporting regarding health is as important and should be as routine within the company as reports regarding timeliness of delivery, cargo loss or contamination, or citations regarding violations of regulations.

A2. EMPLOYEE PARTICIPATION

A2.1 Full participation in developing, implementing, evaluating, and continually improving the SOHSP helps those on board the vessel see the SOHSP as something that is the result of a value they share with vessel owners/operators. Personnel directly involved with the work are often the best source of information on health or safety hazards and often can suggest effective methods for abating those hazards. Shoreside personnel need to be directly and heavily involved with the SOHSP because they are integral in setting the rules and schedules for vessel operation. Shoreside personnel also represent the vessel to management and are the link to the resources and authority necessary for the success of the SOHSP. Specific ways that crewmembers, officers, and shoreside personnel can contribute to the SOHSP include:
A2.1.1 Participating in periodic vessel inspections,
A2.1.2 Evaluating safety and health program materials,
A2.1.3 Developing standard operating procedures that incorporate safe working practices,
A2.1.4 Conducting job safety/hazard analyses (JSAs/JHAs),
A2.1.5 Reviewing and analyzing injury and illness data,
A2.1.6 Participating in risk assessment and risk management activities,
A2.1.7 Participating in accident/incident/problem investigations,
A2.1.8 Developing solutions to health and safety complaints and disputes,
A2.1.9 Evaluating safety and health training activities, and
A2.1.10 Evaluating the safety and health management system.
A2.1.11 Line or operations personnel including crewmembers, officers, and shoreside personnel outside the health and safety staff may need training in health and safety techniques such as job safety/hazard analysis, reviewing injury and illness data for trends, risk assessment, and investigations. This initial training investment enables those who do the work to meaningfully participate in identifying and solving health and safety
problems. Those crewmembers, officers, and shoreside personnel who receive additional training in health and safety and actively participate in the development of the vessel or company SOHSP, or both, also become health and safety “champions” among their peers. Additional information on training is provided in Annex A4.

A2.2 Since health and safety objectives and performance may directly affect crewmembers’ and officers’ current and/or future health and safety, they should be involved in setting those objectives and performance criteria. This participation may be accomplished through health and safety committee involvement, labor negotiations, or other mechanism suitable to the specific company. Refer to Annex A1, Section A1.3 for examples of health and safety objectives and performance criteria.

A2.3 Employees should:

A2.3.1 Fully understand (including underlying principles) and follow established standard operating procedures and safety rules.
A2.3.2 Report unsafe conditions or actions to supervisor as soon as they become aware of them.
A2.3.3 Report all injuries to supervisor promptly.
A2.3.4 Report all accidents, near misses, or problems to supervisor promptly.
A2.3.5 Use personal protective equipment (PPE) in good working condition where it is required.
A2.3.6 Do not remove or defeat any safety device or safeguard.
A2.3.7 Encourage shipmates by words and behavior to follow standard operating procedures and use safe work practices on the job.
A2.3.8 Make suggestions to supervisor or safety committee representative about changes to operating procedures, work practices, or equipment that will improve safety.

A3. HAZARD ANTICIPATION, IDENTIFICATION, EVALUATION AND CONTROL

A3.1 Potential hazards on the vessel and created by the vessel should be systematically anticipated, identified, evaluated, and controlled. Hazards that should be discovered, evaluated, and controlled by the SOHSP include hazards addressed by international conventions and national regulations and other hazards that are causing or likely to cause illness, death, or serious physical harm to workers or the public. Types of hazards to consider may include:

A3.1.1 Hazardous atmospheres caused by oxygen deficiency, flammable or toxic gases or vapors, and biological agents,
A3.1.2 Chemical hazards and the proper handling of vessel generated hazardous wastes,
A3.1.3 Physical hazards including noise, vibration, radiation, electricity, uncontrolled mechanical energy, and shifting cargoes that may engulf a crewmember,
A3.1.4 Ergonomic factors including fatigue, workstation design, and poor team practices,
A3.1.5 Collisions, groundings, or rammings and their resultant impacts, and
A3.1.6 Drowning.

A3.2 Methods of anticipation include:

A3.2.1 Systematic requirements for vessel and equipment design and modification review by qualified health and safety personnel,
A3.2.2 Periodic management review of the vessel and its operation, its equipment, and its fitness for purpose,
A3.2.3 A procurement system that automatically requires consideration of health and safety aspects of items ordered,
A3.2.4 Consideration of fitness for current conditions, and
A3.2.5 Systematic review of vessel and shoreside team practices.

A3.3 Methods of identifying hazards include:

A3.3.1 Vessel inspections,
A3.3.2 Industrial hygiene exposure assessments of chemical and biological hazards including inhalation and dermal exposure routes and physical hazards such as vibration and ergonomic hazards,
A3.3.3 Job safety analyses including risk assessment, both statistical and expert opinion based,
A3.3.4 Employee hazardous condition notification system including easy-to-understand labeling system for all possible mechanical and chemical hazards,
A3.3.5 Review of available safety and health data to identify trends,
A3.3.6 Readers interested in physical standards may refer to U.S. Coast Guard Navigation and Vessel Inspection Circular 2-98, Physical Evaluation Guidelines for Merchant Mariner’s Documents and Licenses, and

A3.4 Methods of hazard evaluation include:

A3.4.1 Comparison of industrial hygiene exposure levels to standards identified in the SOHSP (for example, standards required by regulation or prudent levels adopted by the company in the absence of regulatory requirements),
A3.4.2 Risk analysis tools, including:
A3.4.2.1 Hazard effects and control analysis,
A3.4.2.2 Hazard control analysis,
A3.4.2.3 Fault tree analysis of possibilities based on expert opinion,
A3.4.2.4 Management oversight and risk analysis, and
A3.4.2.5 Task hazard analysis.
A3.4.5 Methods of hazard control are hierarchical. In order of preference, they include:

A3.5.1 Inherent safe design and verification of design output to design requirements,
A3.5.2 Material substitution such as:
A3.5.2.1 Nonhazardous insulation for asbestos lagging,
A3.5.2.2 Citrus-based cleaning agents for solvent-based cleaning agents, and
A3.5.2.3 Nontoxic paint for toxic paint.
A3.5.3 Engineering controls such as:
A3.5.3.1 Closed gauging,
A3.5.3.2 Vapor recovery systems, and
A3.5.3.3 Climate-controlled spaces such as control booths in engine rooms.
A3.5.4 Administrative controls such as:
A3.5.4.1 Systematic review for fitness of vessel for operations,
A3.5.4.2 Standard operating procedures that incorporate safe work practices. Some activities that might require standard operating procedures with integrated safe work practices include:
A3.5.4.3 Machinery startup and shutdown operations,
A3.5.4.4 Emergency response to machinery failures,
A3.5.4.5 Getting underway and entering port operations,
A3.5.4.6 Cargo loading and unloading operations,
A3.5.4.7 Response to unplanned or emergency situations during cargo operations,
A3.5.4.8 Man overboard procedures,
A3.5.4.9 Lifeboat-launching procedures,
A3.5.4.10 Watchkeeping procedures,
A3.5.4.11 Teamworking procedures such as bridge resource management taught in simulators with practice by actual team members,
A3.5.4.12 Prejob planning and briefings,
A3.5.4.13 Job hazard/safety analyses (JHAs/JSAs),
A3.5.4.14 Emergency procedures,
A3.5.4.15 Systematic inspection of incoming equipment and equipment in use to ensure conformation to specifications identified in the SOHSP (for example, personal protective equipment),
A3.5.4.16 An easy-to-understand labeling system for all possible mechanical and chemical hazards, and
A3.5.4.17 Occupational medical surveillance programs tailored to vessel and cargo hazards.
A3.5.5 Specific programs that need special attention within the overall SOHSP:
A3.5.5.1 Respiratory protection program,
A3.5.5.2 Hearing loss prevention program,
A3.5.5.3 Safe lifting procedures,
A3.5.5.4 Permit-to-work programs for operations such as lock out and tag out, tank or hold cleaning operations, confined space entry, hot work operations, including a gas-freeing program, working aloft, and
A3.5.5.5 Health and safety equipment control, calibration, and maintenance procedures.
A3.5.6 Security procedures to control entry and exit of personnel to and from the vessel
A3.5.7 Basic safety rules such as:
Do not do things which are unsafe to get the job done. If a necessary activity is unsafe, report it to the supervisor so it can be evaluated and alternate methods developed.
Mechanical guards must be kept in place at all times when machinery is being operated. Do not remove or disable any safety device!
No person may operate a piece of equipment unless they have been trained and are authorized. Notify supervisor that training is needed if asked to perform a function not learned in meeting the requirements for your license.
Use personal protective equipment whenever it is required.
Obey all safety warning signs.
Smoking is only permitted in designated locations and may be entirely prohibited at certain times, such as during cargo transfer operations.
Good housekeeping is an important part of accident prevention. Replace all tools and supplies after use. Do not allow rubbish or debris to accumulate where they will become a hazard.
A3.5.8 Employee assistance and wellness programs,
A3.5.9 Preemployment chemical tests for dangerous drugs,
A3.5.10 Incentive programs such as safety awards, bonuses, and vessel competitions, and
A3.5.11 Disciplinary policy that provides for progressive consequences depending on the severity or repetition of the violation of a safety rule, or both.
A3.5.12 Personal protective equipment such as:
A3.5.12.1 Safety glasses, goggles, hearing protection, safety shoes, protective clothing, chemical protective booties, respiratory protection, and
A3.5.12.2 Impervious gloves for food handlers as appropriate.
A3.5.13 Preventive maintenance of the vessel and equipment and basic housekeeping programs.

A4. TRAINING

A4.1 Training to enable all employees to recognize hazards and to take appropriate precautions should include:
A4.1.1 General orientation to the company,
A4.1.2 Overview of the company’s health and safety program,
A4.1.3 Vessel orientation including access and egress,
A4.1.4 Emergency procedures in case of fire, confined space entry incident, release of hazardous chemicals or cargo, and overexposure,
A4.1.5 The nature of potential hazards to which employees may be exposed during routine tasks and how to recognize symptoms of exposure,
A4.1.6 Use of protective measures, such as standard operating procedures that incorporate safe work practices, and protective equipment and clothing (refer to Annex A3, Section A3.5, Hazard Control).

A4.1.7 Specific programs including respiratory protection, confined space entry, hearing loss prevention, lockout-tagout, fall protection, safe lifting, health and safety equipment control, calibration and maintenance, and

A4.1.8 Recognition and control of fatigue.

A4.2 Additional training for those with specific health or safety responsibilities may include:

A4.2.1 Risk assessment and risk management including:

A4.2.1.1 Health and safety data trend analysis,
A4.2.1.2 Job safety analysis, and
A4.2.1.3 Shipboard watch implications.

A4.2.2 Fatality, injury, illness, “near miss” incident, and problem investigation and root cause analysis.

A4.3 Effective worker protection programs do not stop at initial training. Effective programs evaluate the success of the training provided and offer refresher training on both a routine and as-needed basis.

A4.4 Elaborate training programs solely related to safety and health are not always needed. Integrating consideration of safety and health protection into all organizational activities is the key to effectiveness. Safety and health information should be integrated into other training about performance requirements and job practices.

A5. RECORD KEEPING

A5.1 Records are needed to document hazard control efforts such as job hazard analyses, industrial hygiene sampling, and training. Data collection systems that enable trend analysis help in identifying injuries and illnesses with common causes. A review of shipboard personnel injury and illness experience over a period of time may reveal patterns of injury and illness with common causes, which can be addressed. Similarly, a review of accidents, “near miss” incidents, or problems over time can reveal patterns of dangerous practice, which need correction to assure safety. The correlation of changes in injury, illness, and “near miss” incident or problem experience with changes in the safety and health program, operations, work processes, and personnel may help to identify potential causes and likelihood of personnel accidents, injuries, and illnesses, and danger or risk to the public. Audits that evaluate the effectiveness of the health and safety program can be used to identify weak points in the system.

A5.2 Examples of records that should be maintained include:

A5.2.1 Death, injury, illness, accident, “near miss” incident, and problem data including:

A5.2.1.1 Investigation reports and root cause analysis (see also Annex A7, Fatality, Injury, Illness, and Incident Investigation), and
A5.2.1.2 Injury, illness, near miss, and problem rates.

A5.2.2 Hazardous condition notifications and abatement actions,
A5.2.3 Crew member safety suggestions,
A5.2.4 Industrial hygiene monitoring results for both personal and area samples,
A5.2.5 Job safety analyses,
A5.2.6 Safety committee reports,
A5.2.7 Safety inspection reports or log entries,
A5.2.8 Medical surveillance data (aimed at identifying exposures so that proper interventions, including improvement of hazard controls, may be initiated),
A5.2.9 Training (refer to Annex A4 for a discussion of recommended training):
A5.2.9.1 Record training outline, date, and attendance,
A5.2.9.2 Record completion of courses such as fire fighting and confined space entry schools, and
A5.2.10 Safety and health management system audits (refer to Annex A8 for an example).

A5.3 The extent of recordkeeping necessary to document the effectiveness of the program will vary depending on the size of the company, level and nature of exposure to hazards on the vessel, and other factors. The records should be maintained as long as necessary in light of their intended use.

A5.4 Records of individual ships should also be shared with other ships and analyzed as a larger base of data to gain information on frequency of problems to identify trends better.

A6. CONTRACT OR THIRD PARTY PERSONNEL

A6.1 The vessel owner/operator or the master/person-in-charge, or both, should provide information on applicable elements of the company’s health and safety program, vessel hazards, safety rules, standard operating procedures, and emergency procedures with contract or third party personnel who may be exposed to vessel or cargo hazards.

A6.2 The contractor or third party should inform his/her employees of the applicable elements of the vessel’s health and safety program and of any known vessel or cargo hazards to
which his/her employees may be exposed. The contract or third party person-in-charge should also direct his/her employees to follow the health and safety rules of the vessel to the extent that they meet or exceed the contractor’s or third party’s own requirements.

A6.3 The contract or third party person-in-charge should inform the vessel’s master or person-in-charge of any health and safety hazards presented by their work and how they will address those hazards. The contract or third party person-in-charge should also inform the vessel personnel of any other health and safety hazards in the course of their work on the vessel.

A6.4 During the initial exchange of information regarding vessel hazards and hazards presented by the work intended, the actions of the contractor or third party toward the health and safety of the vessel crew and their own employees should be clearly identified. Likewise, the actions of the vessel personnel toward the health and safety of the contractor or third party should be clearly identified. Emergency procedures should be clearly agreed upon in advance.

A7. FATALITY, INJURY, ILLNESS AND INCIDENT INVESTIGATION

A7.1 The objective of an investigation is to prevent related incidents from recurring. An investigation should identify the circumstances of the injury, illness, or incident and reveal the proximate causes, contributing factors, and root causes by gathering and analyzing information and drawing conclusions. Identification and correction of causes may prevent similar incidents from recurring. Furthermore, identifying and correcting a true root cause may prevent other, apparently unrelated incidents, giving even more return on the effort expended to identify root causes. For example, if a problem with the company’s training system was identified as the root cause for a confined space incident, then correcting the entire training system may prevent an injury that would have been caused by an untrained person improperly operating a piece of machinery.

A7.2 Start the investigation as soon as possible after the incident occurs. Interview workers involved in the incident and all witnesses. Discover situations leading up to the incident including several days before. These situations may include contributing factors. (Human factors including fatigue often are found as root or contributing factors and may accumulate over a period of time.) Examine the location of the incident and identify factors associated with the incident. Interview other company personnel as needed to determine root causes. Document the investigation and recommendations.

A7.3 The final report should include:

A7.3.1 A summary outlining the basic facts of the incident,
A7.3.2 A narrative detailing the circumstances of the casualty or near incident,
A7.3.3 Analysis and comment that lead to logical conclusions or findings, establishing all the factors, including root cause(s) that contributed to the incident, and
A7.3.4 Immediate and long-term recommendations aimed at preventing similar accidents and correcting root causes.

A7.4 It may be helpful to categorize investigation data. An example of a one-page form divided into information categories is provided (Fig. A7.1). Additional pages might be used to capture the summary, narrative, analysis, and recommendations (Fig. A7.2).

A7.5 The information in this annex was drawn from the references below. Further guidance regarding accident investigation may be obtained from IMO A.849 (20) and Refs (6 and 7).

FIG. A7.2 Statement Form
A8. SYSTEMATIC SHIPBOARD OCCUPATIONAL HEALTH AND SAFETY PROGRAM EVALUATION

A8.1 Tools that may help with program evaluation include:

A8.1.1 Trend analysis of fatality, injury, illness, and “near miss” incident statistics,
A8.1.2 Trend analysis of records of “unsafe acts or behaviors”,
A8.1.3 Review of vessel safety committee reports and recommendations, and
A8.1.4 Review of hazardous condition notifications and abatement actions.

A8.2 Performance measures that may assist in program evaluation include:

A8.2.1 Lost time incident rate,
A8.2.2 Fatality rate,
A8.2.3 Acute toxic exposure incidents per 1000 employee work hours,
A8.2.4 Number of nonconformities with standard operating procedures per 100 employee work hours,
A8.2.5 Percentage of training required by SOHSP completed on schedule,
A8.2.6 Percentage of annual respiratory fit testing completed on schedule, and
A8.2.7 Percentage of annual medical monitoring exams completed on schedule.

A8.3 The audit tool may be used to evaluate a SOHSP. The elements scored in the audit tool are the first seven elements of a SOHSP. Some elements are further divided into factors that are individually scored. The auditor should objectively score the vessel’s SOHSP on each of the individual factors and elements after obtaining the necessary information to do so.

A8.4 Calculate the overall SCORE, as follows:

A8.4.1 Score each element:
A8.4.1.1 The score for the Management Commitment and Leadership Element is the lower of the two scores of the General and Implementation Factors.
A8.4.1.2 The score for the Employee Participation Element is the lower of the two scores for the General and Hazard Reporting Factors.
A8.4.1.3 The score for the Hazard Anticipation, Identification, Evaluation and Control Element is the average of all six factors.
A8.4.1.4 The scores for single-factor elements are the scores for the factor.

The overall SCORE is the average score of the seven element scores and may be assigned a “verbal” description based upon the score.

TABLE A8.1 Management Commitment and Leadership

<table>
<thead>
<tr>
<th>General</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management commitment and leadership is a precondition for an effective SOHSP.</td>
</tr>
</tbody>
</table>

1. Management demonstrates no policy, goals, objectives, or interest in safety and health issues on this vessel.
2. Management sets and communicates safety and health policy and goals, but remains detached from all other safety and health efforts.
3. Management follows all safety and health rules and gives visible support to the safety and health efforts of others.
4. Management participates in significant aspects of the site’s safety and health program, such as site inspections, incident reviews, and program reviews. Incentive programs that discourage reporting of accidents, symptoms, injuries, or hazards are absent. Other incentive programs may be present.
5. Site safety and health issues are regularly included on agendas of management operations meetings. Management clearly demonstrates—by involvement, support, and example—the primary importance of safety and health for everyone on the work site. Performance is consistent and sustained or has improved over time.

TABLE A8.2 Management Commitment and Leadership

<table>
<thead>
<tr>
<th>Implementation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resources:</td>
</tr>
<tr>
<td>• budget</td>
</tr>
<tr>
<td>• information</td>
</tr>
<tr>
<td>• expertise/training</td>

</tr>
<tr>
<td>Defined and assigned responsibilities</td>
</tr>
<tr>
<td>Commensurate authority to carry out responsibilities</td>
</tr>
<tr>
<td>Accountability</td>
</tr>
</tbody>
</table>

1. Tools to implement a safety and health program are inadequate or missing.
2. Some tools to implement a safety and health program are adequate and effectively used; others are ineffective or inadequate. Management assigns responsibility for implementing a site safety and health program to identified person(s). Management’s designated representative has authority to direct abatement of hazards that can be corrected without major capital expenditure.
3. Tools to implement a safety and health program are adequate, but are not all effectively used. Management representative has some expertise in hazard recognition and applicable standards. Management keeps or has access to applicable standards on the unit and seeks appropriate guidance for interpretation of the standards. Management representative has authority to order/purchase safety and health equipment.
4. All tools to implement a safety and health program are more than adequate and effectively used. Written safety procedures, policies, and interpretations are updated based on reviews of the safety and health program. Safety and health expenditures, including training costs and personnel, are identified in the vessel budget. Hazard abatement is an element in management (officers/persons in charge/supervisors) performance evaluation.
5. All tools necessary to implement a good safety and health program are more than adequate and effectively used. Management safety and health representative has expertise appropriate to vessel size and operation and has access to professional advice when needed. Safety and health budgets and funding procedures are reviewed periodically for adequacy.

TABLE A8.3 Employee Participation

<table>
<thead>
<tr>
<th>General</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee participation provides the means through which those who actually do the work identify hazards, recommend and monitor abatement, and otherwise participate in their own protection.</td>
</tr>
</tbody>
</table>

1. Worker participation in workplace safety and health concerns is not encouraged. Incentive programs are present that have the effect of discouraging reporting of incidents, injuries, potential hazards, or symptoms. Employees/employee representatives are not involved in the shipboard health and safety program.
2. Workers and their representatives can participate freely in safety and health activities on the unit without fear of reprisal. Procedures are in place for communication between employer and workers on safety and health matters. Workers are able to refuse or stop work that they reasonably believe involves imminent danger. Workers are paid while performing safety activities.
3. Workers and their representatives are involved in the safety and health program, involved in inspection of work areas, and are permitted to observe monitoring and receive results. Workers and representatives have access to information regarding the shipboard health and safety program including health and safety data trend analysis, job task analysis, and industrial hygiene sampling data. A documented procedure is in place for raising complaints of hazards or discrimination and receiving timely employer response.
4. Workers and their representatives participate in workplace analysis, inspections and investigations, and development of control strategies throughout the vessel, and have necessary training and education to participate in such activities. Workers and their representatives have access to all pertinent health and safety information, including safety reports and audits. Workers are informed of their right to refuse job assignments that pose serious hazards to them pending management response.
5. Workers and their representatives participate fully in development of the safety and health program and conduct of training and education. Workers participate in audits, program reviews conducted by management or third parties, and collection of samples for monitoring purposes, and have necessary training and education to participate in such activities. Employer encourages and authorizes employees to stop activities that present potentially serious safety and health hazards.

TABLE A8.4 Employee Participation

<table>
<thead>
<tr>
<th>Hazard Reporting</th>
</tr>
</thead>
<tbody>
<tr>
<td>A reliable hazard reporting system enables employees, without fear of reprisal, to notify management of conditions that appear hazardous and to receive timely and appropriate responses.</td>
</tr>
</tbody>
</table>

1. No formal hazard reporting system exists, or employees are reluctant to report hazards.
2. Employees are instructed to report hazards to management. Supervisors are instructed and are aware of a procedure for evaluating and responding to such reports. Employees use the system with no risk of reprisals.
3. A formal system for hazard reporting exists. Employee reports of hazards are documented, corrective action is scheduled, and records maintained.
4. Employees are periodically instructed in hazard identification and reporting procedures. Management conducts surveys of employee observations of hazards to ensure that the system is working. Results are documented.
5. Management responds to reports of hazards in writing within specified time frames. The workforce readily identifies and self-correction of hazards; they are supported by management to do so.
Anticipation, identification, and evaluation of hazards involves systematic review of vessel and equipment design, review of the vessel and equipment fitness for current conditions and operations, a procurement system that requires consideration of health and safety aspects of items ordered, vessel inspections, exposure assessments, job safety analyses, mechanisms for employees to report hazardous conditions, and review of health and safety data and records to identify trends.

1. No system or requirement exists for hazard review of planned/changed/new equipment or operations. There are no requirements to consider health and safety aspects of items purchased for the vessel. There is no evidence of comprehensive inspections for safety or health hazards, exposure assessments, routine job safety analysis, or health and safety data trend analysis.

2. The person-in-charge of operation and/or equipment changes considers health and safety implications of the changes but has not had appropriate training to be able to identify all health and safety consequences of the changes. The person responsible for procurement considers health and safety issues but has not been trained on hazards that may be encountered. Inspections for health and safety hazards are conducted by vessel and corporate personnel but only in response to accidents or complaints. The employer has identified principle health and safety standards appropriate for the vessel. Supervisors dedicate time to observing work practices and other safety and health conditions in work areas where they have responsibility.

3. Competent person(s) determine health and safety consequences of proposed changes in high-hazard operations or equipment before the changes occur and appropriate precautions are implemented. Competent person(s) determine health and safety hazards of all items procured and appropriate precautions are taken when the item is used. Vessel and corporate personnel with specific training in health and safety hazards conduct vessel inspections. Inspections in need of correction are documented. Inspections include compliance with relevant regulations, industry standards, and practices. Time periods for corrections are set. Current hazard analyses are written (where appropriate) for all high-hazard jobs and processes; analyses are communicated to and understood by affected employees. Hazard analyses are conducted for jobs/tasks/workstations where injury or illnesses have been reported.

4. Competent person(s) in consultation with a qualified professional determines health and safety consequences of all proposed changes in operations or equipment before the changes occur, and appropriate precautions are implemented. Competent person(s) determine health and safety hazards of all items requested for procurement, identify appropriate substitutions for hazardous items, or ensure appropriate precautions are taken if a substitute cannot be identified. A qualified professional conducted a vessel inspection within the last five years, and competent person(s), trained in items identified by the qualified professional, conduct periodic inspections and appropriate corrective actions are taken promptly. The inspections are planned, with key observations or check points defined and results documented. Corrections are documented through followup inspections. Results are available to workers. Current hazard analyses are documented for all work areas and are communicated and available to all employees.

5. Qualified professionals in consultation with certified safety and health professional(s) analyze health and safety consequences of all proposed changes in operations or equipment, identify substitutions if possible, or ensure appropriate precautions are implemented as the change occurs. Competent person(s) in consultation with qualified professional(s) or certified safety and health professional(s), as needed, identify health and safety hazards of all items requested for procurement and obtain substitutes for hazardous items. Regular inspections are planned and overseen by certified safety or health professionals. Statistically valid random audits of compliance with all elements of the shipboard health and safety program are conducted. Observations are analyzed to evaluate progress. Documented workplace hazard evaluations are conducted by certified safety and health professional(s). Corrective action is documented and hazard inventories are updated.

### TABLE A8.5 Hazard Anticipation, Identification, Evaluation, and Control

<table>
<thead>
<tr>
<th>Anticipation, Identification, and Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workforce exposure to all current and potential hazards should be prevented or controlled by using engineering controls whenever feasible and appropriate, work practices and administrative controls, and personal protective equipment.</td>
</tr>
</tbody>
</table>

1. No preventive maintenance program is in place; breakdown maintenance is the rule.

2. There is a preventive maintenance schedule, but it does not cover everything and may be allowed to slide or performance is not documented. Safety devices on machinery and equipment are generally checked before each shift.

3. A preventive maintenance schedule is implemented for areas where it is most needed; it is followed under normal circumstances. Manufacturers’ and industry recommendations and consensus standards for maintenance frequency are followed. Breakdown repairs for safety-related items are expedited. Safety device checks are documented. Ventilation system function is observed periodically.

4. The employer has effectively implemented a preventive maintenance schedule that applies to all equipment. Vessel experience is used to improve safety-related preventative maintenance scheduling.

5. There is a comprehensive safety and preventive maintenance program that maximizes equipment reliability.
TABLE A8.8 Hazard Anticipation, Identification, Evaluation, and Control

Control—Medical Program

An effective shipboard health and safety program will include a suitable medical program where it is appropriate for the nature of the hazards.

1. Management is unaware of, or unresponsive to occupational medical surveillance needs. Required medical surveillance, monitoring, and reporting are absent or inadequate.

2. Required medical surveillance, monitoring, removal, and reporting responsibilities for applicable standards are assigned and carried out, but results may be incomplete or inadequate.

3. Medical surveillance, removal, monitoring, and reporting comply with applicable standards. Employees report early signs/symptoms of job-related injury or illness and receive appropriate treatment.

4. Health care providers provide followup on employee treatment protocols and are involved in hazard identification and control on the vessel. Medical surveillance addresses conditions not covered by specific standards. Employee concerns about medical treatment are documented and responded to.

5. Health care providers periodically observe the work areas and activities and are fully involved in hazard identification and training.

TABLE A8.9 Hazard Anticipation, Identification, Evaluation, and Control

Control—Emergency Preparedness—Planning and Drills

There should be appropriate planning, training/drills, and equipment for response to emergencies.

1. Little or no effort to prepare for emergencies.

2. Emergency response plans for fire, chemical, and weather emergencies as required by regulation are present. Training is conducted as required by the applicable regulation. Some deficiencies may exist.

3. Persons with specific training have prepared emergency response plans. Appropriate alarm systems are present. Employees are trained in emergency procedures. The emergency response extends to spills and incidents in routine operation. Adequate supply of spill control and PPE appropriate to hazards on site is available.

4. Abandoned ship drills are conducted in accordance no less than annually. The plan is reviewed by a qualified safety and health professional.

5. Vessel personnel with emergency response assignments have adequate training. All potential emergencies have been identified. Emergency response plans and performance are reevaluated at least annually and after each significant incident. Procedures for terminating an emergency response condition are clearly defined.

TABLE A8.10 Hazard Anticipation, Identification, Evaluation, and Control

Control—Emergency Preparedness—First Aid

First aid/emergency care should be readily available to minimize harm if an injury or illness occurs.

1. First aid/emergency care cannot be ensured.

2. First aid/emergency care is available on every shift.

3. Personnel with appropriate first aid skills commensurate with likely hazards on the vessel and as required by applicable regulations are available. Management documents and evaluates response time on a continuing basis.

4. Personnel with certified first aid skills are always available on-site; their level of training is appropriate to the hazards of the work being done. Adequacy of first aid is formally reviewed after significant incidents.

5. Personnel trained in advanced first aid and/or emergency medical care are always available on-site.

TABLE A8.11 Safety and Health Training

General

Safety and health training should cover the safety and health responsibilities of all personnel who work on the vessel or affect its operations. It is most effective when incorporated into other training about performance requirements and job practices. It should include all subjects and areas necessary to address the hazards on the vessel.

1. Vessel personnel depend on experience and peer training to meet needs. Master/person-in-charge/others in supervisory positions demonstrate little or no involvement in safety and health training responsibilities.

2. Some orientation training is given to new hires. Some safety training materials (for example, pamphlets, posters, videotapes) are available or are used periodically at safety meetings, but there is little or no documentation of training or assessment of worker knowledge for a given topic. Masters/persons-in-charge/and others in supervisory positions generally demonstrate awareness of safety and health responsibilities, but have limited training themselves or involvement in the site’s training program.

3. Training includes regulatory rights and access to information. Training required by regulations is provided to all vessel employees. Supervisors attend training in all subjects provided to employees under their direction. Vessel personnel can generally demonstrate the skills/knowledge necessary to perform their jobs safely. Records of training are kept and training is evaluated to ensure it is effective.

4. Knowledgeable persons conduct safety and health training that is scheduled, assessed, and documented, and addresses all necessary technical topics. Employees are trained to recognize hazards, violations of regulations, and vessel practices. Employees are trained to report violations to management. Training is followed up with performance observation and feedback. All site employees—including supervisors and masters/persons-in-charge—can demonstrate preparedness for participation in the overall safety and health program. There are easily retrievable scheduling and record keeping systems.

5. Knowledgeable persons conduct safety and health training that is scheduled, assessed, and documented. Training covers all necessary topics and situations, whether addressed in regulations or not, and includes all persons on the vessel (unlicensed personnel to the master or person-in-charge, contractors, and temporary employees). Employees participate in creating site-specific training methods and materials. Employees are trained to recognize inadequate responses to reported program violations. Retrievable recordkeeping system provides for appropriate retraining, makeup training, and modifications to training as the result of evaluations.
### TABLE A8.12 Record Keeping

Data Collection and Analysis

An effective shipboard occupational health and safety program will collect and analyze injury, illness, and “near miss” incident data for indications of sources and locations of hazards, and jobs that experience higher numbers of incidents. By analyzing injury, illness, and “near miss” incident trends over time, patterns with common causes can be identified and prevented.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Little or no collection and/or analysis of injury, illness, or “near miss” incident data. Exposure monitoring is not conducted or documented.</td>
</tr>
<tr>
<td>2</td>
<td>Injury, illness, and “near miss” incident data is collected and analyzed, but not widely used for prevention. CG-2692 is completed for all reportable marine casualties. Exposure records and analysis are organized and available to safety personnel.</td>
</tr>
<tr>
<td>3</td>
<td>Injury, illness, and “near miss” incident logs and exposure records are kept, are audited by shoreside management personnel, and are essentially accurate and complete. Rates are calculated so as to identify high-risk areas and jobs. Liability claims are analyzed and the results are used in the program. Significant analytical findings are used for prevention.</td>
</tr>
<tr>
<td>4</td>
<td>Shoreside management and vessel master/person-in-charge and supervisors can identify the frequent and most severe problem areas, the high-risk areas and job classifications, and any exposures that exceed OSHA PELs, ACGIH TLVs, or company standards. Data are fully analyzed and effectively communicated to employees. Injury, illness, and “near miss” incident data are audited and certified by a responsible person.</td>
</tr>
<tr>
<td>5</td>
<td>All levels of management and the workforce are aware of results of data analyses and resulting preventive activity. External audits of accuracy of injury, illness, and “near miss” incident data, including review of all available data sources are conducted. Scientific analysis of health information, including nonoccupational databases is included where appropriate in the program.</td>
</tr>
</tbody>
</table>

### TABLE A8.13 Contract and Third Party Personnel

General

An effective safety and health program protects all personnel on the vessel, including the employees of contractors, subcontractors, and third party personnel. It is the responsibility of shoreside management and the vessel master or person-in-charge to address contractor safety and third party safety.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Shoreside management and the vessel master or person-in-charge make no provision to include contractors and third party personnel within the scope of the vessel’s health and safety program.</td>
</tr>
<tr>
<td>2</td>
<td>Vessel safety policy requires contractor and third party personnel to conform to applicable regulations and other legal requirements.</td>
</tr>
<tr>
<td>3</td>
<td>The master/person-in-charge designates a representative to monitor contractor and third party safety and health practices, and that individual has authority to stop contractor practices that expose host or contractor employees to hazards. Management informs contractor and employees of hazards present at the facility.</td>
</tr>
<tr>
<td>4</td>
<td>Shoreside management investigates a contractor’s safety and health record as one of the bidding criteria. Shoreside management contacts third party personnel management if necessary to correct unsafe third party behavior.</td>
</tr>
<tr>
<td>5</td>
<td>The vessel’s health and safety program ensures protection of everyone employed at the work site including full-time employees, temporary employees, contractors, and third party personnel.</td>

**APPENDIX**

(Nonmandatory Information)

**X1. RATIONALE**

X1.1 This guide was developed by a group of management, labor, and government people involved in the shipping industry. Members of the group agreed that guidance in the area of occupational health and safety would be helpful to the shipping industry. However, they did not want a detailed prescriptive standard, nor did they want to produce something that already existed. The group researched existing guidance at the national and international levels and came to the agreement that research existed that outlined key elements to effective health and safety program implementation. These key elements are contained in this guide with amplifying information specifically geared toward the shipping industry. The literature used in development of the guide is listed in the Reference Section (1-7).

6 The boldface numbers given in parentheses refer to a list of references at the end of the text.

**REFERENCES**

(2) *How to Write an Accident Prevention Program*, State of Washington Department of Labor and Industries, 1996 (Draft).

1. Scope

1.1 This specification covers the requirements for electrical liquid level indicating equipment for shipboard low pressure and high pressure tanks containing freshwater, feed water, potable water, seawater, wastewater, diesel fuel, lubricating oil, contaminated oil, refrigerants, JP fuels, and various other fluids. Application includes compensating tanks in which the equipment must locate the interface.

1.2 Each liquid level indicating equipment typically consists of the following components:

(a) One or more sensing devices;
(b) Flexible interconnections, if needed;
(c) Primary indicator panel assembly;
(d) Auxiliary indicator panel assembly, when required; and
(e) Portable indicator panel assembly, when required.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only. Where information is to be specified, it shall be stated in SI units.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.5 Special requirements for naval shipboard applications are included in the Supplement to this standard.

2. Referenced Documents

2.1 ASTM Standards:
D 3951 Practice for Commercial Packaging

2.2 ISO Standards:
9001 Quality System Model for Quality Assurance in Design/Development, Production, Installation, and Servicing

3. Terminology

3.1 Definitions:

3.1.1 hysteresis—maximum difference in output, at any measurand value within the specified range, when the value is approached first with increasing and then with decreasing measurand.

3.1.2 insulation resistance—the resistance measured between insulated portions of a liquid level indicating equipment and between insulated portions of a liquid level indicating equipment and ground when a specified dc voltage is applied under specified conditions.

3.1.3 output—electrical or numerical quantity, produced by a liquid level indicating sensor or measurement system, that is a function of the applied measurand.

3.1.4 pressure cycling—the specified minimum number of specified periodic pressure changes over which a liquid level indicating sensor will operate and meet the specified performance.

3.1.5 process medium—the measured fluid (measurand) that comes in contact with the sensing element.

3.1.6 repeatability—ability of a liquid level indicating equipment to reproduce output readings when the same measurand value is applied to it consecutively, under the same conditions, and in the same direction.

3.1.7 response—the measured output of a liquid level indicating sensor to a specified change in measurand.

3.1.8 signal conditioner—an electronic device that makes the output signal from a sensor element compatible with a readout system.

3.1.9 wetted parts—liquid level indicating equipment components with at least one surface in direct contact with the process medium.

4. Designation

4.1 Designation—Most liquid level indicating equipment manufacturers use designations or systematic numbering or identifying codes.

4.2 Design—Liquid level indicating equipment typically consist of a sensing device that may or may not be in contact with the process medium, a transduction element that modifies the signal from the sensing device to produce an electrical output, and an indicator panel assembly to show the level of the medium being measured. Some parts of the sensing device may be hermetically sealed if those parts are sensitive to and may be exposed to moisture. The output cable must be securely fastened to the body of the sensing device. A variety of sensing
4.2.1 Sensing Techniques—The sensing device typically does not use any part of the tank structure as part of the sensing device.

4.2.1.1 Admittance and Impedance—The admittance and impedance sensing technique uses the apparent resistance to the current flow of an alternating current in the sensing device circuit or its reciprocal with respect to the level of the measured fluid in the tank.

4.2.1.2 Magnetic Float—The magnetic float sensing technique uses a float with embedded magnets to change the circuit status of the sensing device and produce an electrical signal proportional to the float’s position with respect to the level of the measured fluid in the tank.

4.2.1.3 Differential Pressure—The differential pressure-sensing technique uses the pressure difference regardless of the ambient pressure to change the circuit status of the sensing device and produce an electrical signal proportional to the level of the measured fluid in the tank.

4.2.1.4 Time Domain Reflectometry—The time domain reflectometry sensing technique uses a high frequency electromagnetic wave transmitted along a transmission line, wire, cable, or rod to determine the level of the measured liquid(s) by detecting changes in and timing the reflected energy.

4.2.1.5 Capacitive—The capacitive-sensing technique uses the change in capacitance of the sensing device to produce an electrical signal proportional to the level of the measured fluid in the tank.

4.2.1.6 Resistance Tape—The resistance-tape-type sensing technique uses the change in circuit resistance in the sensing device to produce an electrical signal proportional to the level of the measured fluid in the tank.

4.2.1.7 Static Pressure—The static head technique measures the static (head) pressure caused by the measured liquid relative to the ambient pressure to change the circuit status of the sensing device and produce an electrical signal proportional to the level of the measured fluid in the tank.

4.2.1.8 Radar—The radar technique uses a high frequency electromagnetic wave transmitted through the air, including guided inside a hollow tube, to determine the level of the measured liquid(s) by detecting changes in and/or timing the reflected energy.

4.2.1.9 Ultrasonic—The ultrasonic technique uses high frequency sonic waves transmitted either through the air or in the liquid to be measured, to determine the measured liquid(s) level by detecting changes in and/or timing the reflected energy.

4.3 Process Medium—The following are the most common types of process media. The first column identifies fluids that are measured in the tank. The second column identifies the liquid or gas that interfaces with the measured fluid.

4.4 Pressure Range—The liquid level indicating equipment must be able to withstand the expected fluid pressures in the tank. Pressure range specification must take into account expected pressures to be encountered in differing tank sizes and fluid types for a particular sensor type.

4.5 Display—The display for liquid level indication is typically specified as analog, digital, or both.

5. Ordering Information

5.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with 5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

5.2 Acquisition Requirements—Acquisition documents must specify the following:

(a) Title, number, and date of this specification;
(b) Manufacturer’s part number;
(c) Sensing technique;
(d) Application;
(e) Pressure range;
(f) Display requirements (see 4.5) and indication range;
(g) Indicator panel assembly mounting method;
(h) Indicator panel assembly requirements;
(i) System operating characteristics;
(j) Materials;
(k) Environmental requirements;
(l) Quantity of liquid level indicating equipment required;
(m) Size and weight restrictions (see 7.5);
(n) Critical service life requirements (see 8.1);
(o) Performance requirements (see 8.2);
(p) Special surface finish requirements (see 9.1);
(q) When certification is required (see Section 13);
(r) Special marking requirements (see Section 14);
(s) Special packaging or package marking requirements (see Section 15);
(t) When ISO 9001 quality assurance system is not required (see 16.1); and
(u) Special warranty requirements (see 16.2).

6. Materials and Manufacture

6.1 Sensing Devices—The materials for the sensing devices and wetted pans shall be selected for long-term compatibility (see 8.1) with the process medium (see 4.3).
6.2 Material Inspection—The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with the specifications and standards as applicable.

7. Physical Properties

7.1 Enclosure—Unique or special enclosure requirements shall be specified in the acquisition requirements (see 5.2).

7.2 Liquid Level Indicating Equipment Mounting—Liquid level indicating equipment is commonly mounted using brackets or similar hardware.

7.3 External Configuration—The outline drawing shall show the configuration with dimensions in SI units (inch-pound units). The outline drawing shall include limiting dimensions for electrical connections if required. The outline drawing shall indicate the mounting method with hole size, center location, and other pertinent dimensions. Where threaded holes are used, thread specifications shall be provided.

7.4 Electrical Connection—Electrical flexible interconnections shall be provided with each liquid level indicating sensor as specified in the contract (see 5.1).

7.5 Size and Weight—The user may have intended applications in which size and weight are limited. Size and weight restrictions shall be specified in the acquisition requirements (see 5.2).

8. Performance Requirements

8.1 Service Life—The user may have a minimum specified service life requirement that may be critical. Critical service life requirements shall be specified in the acquisition requirements (see 5.2).

8.2 Liquid Level Indicating Equipment Performance—Performance tolerances are usually specified in percent of indicator full scale. Critical performance requirements shall be specified in the acquisition requirements (see 5.2). The following performance characteristics and environmental exposures may or may not be important to each user’s intended application.

- Accuracy
- Response time
- Repeatability
- Hysteresis
- Insulation resistance
- Specific gravity
- Fluid conductivity
- Tank wall proximity
- Inclination
- Spike voltage
- Salt spray
- Pressure
- Vibration
- Shock
- Enclosure
- dc magnetic field
- Electromagnetic interference (EMI)
- Immersion
- Supply line voltage and frequency variation

9. Workmanship, Finish, and Appearance

9.1 Finish and Appearance—Any special surface finish and appearance requirements shall be specified in the acquisition requirements (see 5.2).

10. Inspection

10.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

(a) First article tests (see 10.2) and
(b) Conformance tests (see 10.3).

10.2 First Article Tests—First article test requirements shall be specified, where applicable. First article test methods should be identified for each design and performance characteristic specified. Test report documentation requirements should also be specified.

10.3 Conformance Tests—Conformance testing is accomplished when first article tests were satisfied by a previous acquisition or the product has demonstrated reliability in similar applications. Conformance tests are usually less intensive than first article tests, often verifying that samples of a production lot meet a few critical performance requirements.

11. Number of Tests and Retests

11.1 Test Specimen—The number of test specimens to be subjected to first article tests shall be specified and should depend on the liquid level indicating equipment design. Generally, one liquid level indicating equipment of each type (that is, sensing technique, application, pressure range, display, and indication range) shall be subjected to first article testing.

12. Test Data

12.1 Test Data—Test data shall remain on file at the manufacturer’s facility for review by the buyer upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years or a period of time acceptable to the buyer and manufacturer.

13. Certification

13.1 When specified in the acquisition requirements (see 5.2), the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met.

14. Product Marking

14.1 User specified product marking shall be listed in the acquisition requirements (see 5.2). The minimum data to be clearly marked on each liquid level indicating equipment shall include the following:

(a) Manufacturer’s name,
(b) Manufacturer’s part number,
(c) Serial number or lot number,
(d) Date of manufacture (not required if serial number is traceable to date of manufacture), and
(e) Excitation voltage.

15. Packaging and Package Marking

15.1 Packaging of Product for Delivery—Product should be packaged for shipment in accordance with Practice D 3951.
15.2 Any special packaging or package marking requirements for shipment or storage shall be identified in the acquisition requirements (see 5.2).

16. Quality Assurance

16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see 5.2).

16.2 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:
(a) All materials used to produce a unit and
(b) Workmanship to produce the unit.
Special warranty requirements shall be specified in the acquisition requirements (see 5.2).

17. Keywords

17.1 level indicator; liquid level; sensing device; tank level

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard F25(LLIE)M-99 and this supplement, the requirements of this supplement shall take precedence for equipment acquired by this supplement. This document supersedes MIL-L-23886, Liquid Level Indicating Equipment (Electrical), for new ship construction.

LIQUID LEVEL INDICATING EQUIPMENT (ELECTRICAL)

S1. Scope

S1.1 This specification supplement covers the requirements for electrical liquid level indicating equipment for use in low pressure and high pressure tanks aboard naval ships containing freshwater, feed water, potable water, seawater, wastewater, diesel fuel, lubricating oil, contaminated oil, refrigerants, JP fuels, and various other fluids.

S1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are provided for information only. Where information is to be specified, it shall be stated in SI units.

S2. Reference Documents

250 Enclosures for Electrical Equipment (1000 V Maximum)

S3. Terminology

S3.1 Terminology is consistent with that of Section 3 and the referenced documents.

S4. Designation

S4.1 Designation—For this specification, liquid level indicating equipment designations shall be assigned as specified in S5.1 and listed in the format below:
Example: F25(LLIE)M-MF-SW/AR-LP-A-005/245/250

<table>

6 Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111–5094, Attn: NPODS.
7 Available from NEMA, 1300 N. 17th St., Suite 1847, Rosslyn, VA 22209.
S4.2 Sensing Technique — The sensing technique shall be designated as follows:

<table>
<thead>
<tr>
<th>Fluid Liquid or Gas</th>
</tr>
</thead>
<tbody>
<tr>
<td>CF — Contaminated fuel</td>
</tr>
<tr>
<td>CO — Contaminated oil</td>
</tr>
<tr>
<td>FO — Fuel (diesel fuel, cargo fuel, gasoline)</td>
</tr>
<tr>
<td>FW — Freshwater, potable water, feed water</td>
</tr>
<tr>
<td>HO — Hydraulic oil</td>
</tr>
<tr>
<td>LO — Lubricating oil</td>
</tr>
<tr>
<td>RF — Refrigerants</td>
</tr>
<tr>
<td>SO — Synthetic oil</td>
</tr>
<tr>
<td>SW — Seawater</td>
</tr>
<tr>
<td>TO — Turbine oil</td>
</tr>
<tr>
<td>WO — Waste oil</td>
</tr>
<tr>
<td>WW — Wastewater, sanitary waste</td>
</tr>
</tbody>
</table>

S4.3 Application — The fluid to be measured shall be designated as follows. The first two-letter designation identifies the fluid to be measured in the tank. The second two-letter designation identifies the liquid or gas that interfaces with the measured fluid.

S4.4 Pressure Range — The pressure range under which the sensing device shall operate shall be designated as follows:

<table>
<thead>
<tr>
<th>Pressure Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>AP — Vacuum pressure of 749-mm mercury (29.5–in. mercury) to 138 kPa (20 psig) inclusive.</td>
</tr>
<tr>
<td>VP — Vacuum pressure of 749-mm mercury (29.5–in. mercury) to 689 kPa (100 psig) inclusive.</td>
</tr>
<tr>
<td>LP — From 0 kPa to 689 kPa (0 to 100 psig) inclusive.</td>
</tr>
<tr>
<td>HP — From 696 kPa (101 psig) to maximum pressure as specified (see S5.2).</td>
</tr>
</tbody>
</table>

S4.5 Display — The display shall be designated as follows:

<table>
<thead>
<tr>
<th>Display</th>
</tr>
</thead>
<tbody>
<tr>
<td>A — Analog</td>
</tr>
<tr>
<td>D — Digital</td>
</tr>
<tr>
<td>C — Analog and digital</td>
</tr>
</tbody>
</table>

S4.6 Indication Range — The indication range shall be designated by three numbers, separated by a slash. Each number shall represent a height in millimetres above the bottom of the tank. The first number shall indicate where liquid level indication shall begin. The second number shall indicate where liquid level indication shall end. The third number shall indicate the total height of the tank.

S5. Ordering Information

S5.1 The buyer shall provide the manufacturer with all of the pertinent application data in accordance with S5.2. If special application operating conditions exist that are not in the acquisition requirements, they shall also be described.

S5.2 Acquisition Requirements — Acquisition documents shall specify the following:

<table>
<thead>
<tr>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) Title, number, and date of this specification;</td>
</tr>
<tr>
<td>(b) Part designation (see S4.1);</td>
</tr>
<tr>
<td>(c) National Stock Number (NSN) if available;</td>
</tr>
<tr>
<td>(d) Quantity of liquid level indicating equipment required;</td>
</tr>
<tr>
<td>(e) If pressure range is HP, the maximum pressure required (see S4.4);</td>
</tr>
<tr>
<td>(f) If deviation requests are not required when departing from material guidance (see S6);</td>
</tr>
<tr>
<td>(g) If the maximum height of any individual component is other than 3048 mm (120 in.) or maximum weight of any individual component is other than 16 kg (35 lbs) (see S7.6);</td>
</tr>
<tr>
<td>(h) If primary indicator panel assembly is panel or bulkhead mounted (see S7.9);</td>
</tr>
<tr>
<td>(i) If more than one liquid level display is required for the primary indicator panel assembly (see S7.9);</td>
</tr>
<tr>
<td>(j) If volumetric accuracy is required (see S7.9.1);</td>
</tr>
<tr>
<td>(k) If a control circuit is required and whether settings are to be two high, two low, one high and one low, or two high and two low (see S7.9.2);</td>
</tr>
<tr>
<td>(l) If alarm lights are required on primary indicator panel assembly (see S7.9.3);</td>
</tr>
<tr>
<td>(m) If audible alarm and alarm acknowledge switch are required on primary indicator panel assembly (see S7.9.3);</td>
</tr>
<tr>
<td>(n) If a protective shield is required for primary indicator panel assembly (see S7.9.4);</td>
</tr>
<tr>
<td>(o) If auxiliary indicator panel assembly is required. Specify either panel or bulkhead mounted, and what is required in addition to a liquid level display (see S7.10);</td>
</tr>
<tr>
<td>(p) If portable indicator assembly is required (see S7.11);</td>
</tr>
<tr>
<td>(q) If epoxy coating is required (see S7.13);</td>
</tr>
<tr>
<td>(r) If special purpose equipment is not to be provided (see S7.14);</td>
</tr>
<tr>
<td>(s) If indicator dial is not to be furnished blank or if additional information is to be identified on the dial or if dials are to have other than black letters, numerals, and graduations on a white background (see S7.15.1);</td>
</tr>
<tr>
<td>(t) If red illumination is required for liquid level display (see S7.15.2);</td>
</tr>
<tr>
<td>(u) If audible signals are required for any remote station (see S7.16);</td>
</tr>
<tr>
<td>(v) If dc magnetic field strength requirement is other than 400 A/m (see S8.16 and S12.2.15);</td>
</tr>
<tr>
<td>(w) When first article tests are required (see S10.3);</td>
</tr>
<tr>
<td>(x) Sampling and acceptance numbers for Group A and Group B testing (see S11.1 and S11.3);</td>
</tr>
<tr>
<td>(y) If the inclination angle is other than 45° (see S12.2.8);</td>
</tr>
<tr>
<td>(z) Special product marking requirements (see S14);</td>
</tr>
<tr>
<td>(aa) Special packaging or package marking requirements (see S15);</td>
</tr>
<tr>
<td>(bb) When ISO 9001 quality assurance system is not required (see S16.1); and</td>
</tr>
<tr>
<td>(cc) Special warranty requirements (see S16.2).</td>
</tr>
</tbody>
</table>

S5.3 First Article Tests — When first article testing is required, the buyer should provide specific guidance to offerors whether the item(s) should be a preproduction sample, a first article sample, a first production item, a sample selected from the first production items, or a standard production item from the manufacturer’s current inventory. The number of items to be tested in accordance with S10.4 should be specified. The buyer should include specific instructions in acquisition documents regarding arrangements for tests, approval of first article test results and time period for approval, and disposition of first
articles. Invitations for bids should provide that the buyer reserves the right to waive the requirement for samples for first article testing to those bidders offering a product which has been previously acquired or tested by the buyer; and that bidders offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior buyer approval is presently appropriate for the pending contract. The manufacture of items before buyer approval should be specified as the responsibility of the manufacturer.

S6. Materials

S6.1 General—Toxic materials shall not be used in potable water applications.

S6.2 Metals—Unless otherwise specified herein, all metals used in the construction of liquid level indicating equipment shall be corrosion resistant or treated to provide corrosion resistance. Dissimilar metals shall not be used in contact with each other unless suitable finished to prevent electrolytic corrosion. The materials for wetted parts shall be selected for long-term compatibility (see S4.3) with the contacted fluid, liquid, or gas (see S4.3).

S6.3 Flammable Materials—Materials used in the construction of liquid level indicating equipment shall in the end configuration be noncombustible or fire retardant in the most hazardous of atmosphere, pressure, and temperature to be expected in the application. Fire retardance shall not be achieved by use of nonpermanent additives to the material.

S6.4 Fungus-Resistant Materials—Materials used in the construction of liquid level indicating equipment shall not support the growth of fungus.

S6.5 Solvents, Adhesives, and Cleaning Agents—When chemicals or cements are used in bonding of internal components, no degradation shall result during in-service use.

S7. Physical Properties

S7.1 Configuration—Each liquid level indicating equipment shall consist of the following components:
(a) One or more sensing devices,
(b) Flexible interconnections, if needed,
(c) Primary indicator panel assembly,
(d) Auxiliary indicator panel assembly, when required (see S5.2), and
(e) Portable indicator assembly, when required (see S5.2).

S7.2 Magnetic Float Liquid Level Switches—Magnetic float liquid level switches shall be in accordance with MIL-S-16032.

S7.3 Microprocessors—When microprocessors are used to perform processing and control functions, built-in test (BIT) shall be provided in the form of firmware residing in programmable read only memory. To assist troubleshooting, BIT shall indicate basic failure modes of the equipment such as power supply parameters out of tolerance.

S7.4 Testability—No mechanical or electrical disassembly shall be required for the purpose of obtaining access to test points or adjustments, except for removal of a cover plate.

S7.5 Safety—For JP, CF, CO, WO, and FO applications, the portions of the liquid level indicating equipment inside the tank shall be in accordance with the hazardous area requirements of ABS Rules for Building and Classing Steel Vessels, except flexible interconnections shall be in accordance with S7.8.

S7.6 Size and Weight—Unless otherwise specified (see S5.2), the maximum height of any individual component shall be 3048 mm (120 in.). Unless otherwise specified (see S5.2), the maximum weight of any individual component shall be 16 kg (35 lbs).

S7.7 Interchangeability—In no case shall parts be physically interchangeable or reversible unless such parts are also interchangeable or reversible with regard to function, performance, and strength.

S7.8 Flexible Interconnections—Electrical flexible interconnections, including tank penetration cables, shall have high pressure pin connections in accordance with MIL-C-24231 on high pressure tank penetrations. Flexible interconnections shall permit easy repair, replacement, substitution, or bypassing of sensing devices. No interconnection boxes or junction boxes shall be installed inside of any tank. Flexible interconnections shall be Type I or Type II as specified herein.

S7.8.1 Type I Flexible Interconnections—Type I flexible interconnections shall be used in FO, CF, CO, WO, and JP applications. For sensing techniques other than TD, the cable shall be shielded, water-blocked cable consisting of watertight primary conductors, insulated with crosslinked (XL) modified polyvinylidene fluoride. The primary conductors shall be water blocked and wrapped with polyester tape. The cable jacket shall be XL-modified ethylene-tetrafluoroethylene copolymer. The final cable formulation shall meet the physical characteristics as specified in MIL-C-915. For TD sensing techniques, the cable shall be FEP-jacketed coax cable in accordance with MIL-C-17/127.

S7.8.2 Type II Flexible Interconnections—Type II flexible interconnections shall be used in applications other than FO, CF, CO, WO, and JP applications. Type II flexible interconnections shall be of watertight flexing construction in accordance with MIL-C-915 and MIL-C-915/8, Type DSS, TSS, FSS, and 755. The cable outer jacket shall be butadiene copolymer with an acrylonitrile content of 40 ± 10 % by volume. The final cable formulation shall meet the physical characteristics (tensile strength, elongation, bending endurance, and so forth) as specified in MIL-C-915. For TD sensing techniques, the cable shall be FEP-jacketed coax cable in accordance with MIL-C-17/127.

S7.9 Primary Indicator Panel Assembly—The primary indicator panel assembly shall be as small and lightweight as practicable and arranged for bulkhead or panel mounting as specified (see S5.2). Unless otherwise specified (see S5.2), the primary indicator panel assembly shall provide only a single liquid level display. The primary indicator panel assembly shall consist of devices such as regulated power supply, signal conditioners, controls, and indicators required for proper operation. When specified (see S5.2), a control circuit to be used for actuating an external device, such as an alarm or pump, when liquid level reaches predetermined points shall be provided. Other functional components and parts not included in the sensing device assembly shall be contained within the panel enclosure. Where multiple displays are combined on a single primary indicator panel assembly, there shall be no interaction
between the individual tank liquid level indicating equipment circuits except that a common power supply and operational test device may be used.

S7.9.1 Signal Conditioner—The signal conditioner shall provide a continuous output signal from 0 to 200 µAdc, 4 to 20 mAdc, 0 to 10 Vdc, or 1 to 5 Vdc. The signal conditioner output shall be uninterrupted from empty to full or over that portion of the tank to be measured. Unless volumetric accuracy is specified (see S5.2), the output signal shall be proportional to the actual liquid level height in the tank. When volumetric accuracy is specified, the output of the signal conditioner shall be proportional to the actual liquid level volume in the tank, and the contracting activity will furnish the tank capacity curve. Volumetric accuracy shall not be accomplished by modifications to the indicator dial scale or display.

S7.9.2 Control Circuit—When specified (see S5.2), a control circuit shall be provided that has two (two high, two low, or one high and one low), or four (two high and two low) independently adjustable settings, each of which controls a two-pole double throw switching device with a contact rating of 1 A (inductive) at 115 V, 60 Hz.

S7.9.2.1 Control Circuit Setpoints—The high level control circuit setpoints shall be adjustable from 50 to 98% of the indicated range. The low level control circuit setpoints shall be adjustable from 2 to 50% of the indicated range. No mechanical or electrical disassembly shall be required to access the control circuit setpoint adjustments except for removal of a cover plate. A control circuit test means shall be provided to verify the alarm setpoints and control circuit operation.

S7.9.3 Controls and Indicators—The following controls and indicators shall be mounted on the front panel of the primary indicator panel assembly:

(a) Power-on light (white lens),
(b) Power-on switch,
(c) One or more liquid level displays,
(d) Operational test device,
(e) When required, alarm lights (see S5.2), and
(f) When required, audible alarm and alarm acknowledge switch (see S5.2). Multiposition switches and controls may be used to combine functions.

S7.9.4 Protective Shield—The protective shield, when required (see S5.2), shall be rigid, transparent, shatterproof, and positioned as close to the indicator as possible to protect the indicator from accidental damage. The protective shield shall not trap moisture and shall be easily removable.

S7.10 Auxiliary Indicator Panel Assembly—When required (see S5.2), the auxiliary panel enclosure shall be as small and lightweight as practicable and arranged for bulkhead or panel mounting as specified (see S5.2). Unless otherwise specified (see S5.2), only a liquid level display shall be mounted on the front panel. The liquid level display shall be of the same type as on the primary indicator panel assembly. In the event of failure of the auxiliary indicator panel assembly, a device shall be provided on the primary indicator panel assembly to allow isolation of the auxiliary indicator panel assembly. With the auxiliary indicator panel assembly isolated, the primary indicator panel assembly shall continue to operate as specified herein.

S7.11 Portable Indicator Panel Assembly—When required (see S5.2), the portable indicator panel assembly shall meet the requirements of the primary indicator panel assembly (see S7.9), except bulkhead or panel mounting provisions are not required.

S7.12 Mounting—Component mounting devices or brackets shall be supplied with the liquid level indicating equipment.

S7.13 Coating—For all seawater applications and when required (see S5.2), the stationary metallic parts of the liquid level indicating equipment which may come in contact with the fluid to be measured, excluding flexible interconnections, shall be powder epoxy coated.

S7.14 Maintainability—The liquid level indicating equipment shall facilitate assembly, disassembly, fault isolation, operational test (for example, setting or checking alarm setpoints and setting or checking full-scale meter deflection), and preventative maintenance without the aid of special tools or special purpose equipment. Unless otherwise specified (see S5.2), special purpose equipment required for initial setup, equipment change, or troubleshooting shall be provided with the liquid level indicating equipment. Functional pans shall be readily identifiable, accessible, and removable for replacement. If possible, all equipment components, excluding float when used, shall be maintainable outside the tank.

S7.15 Liquid Level Display—Liquid level displays shall be 0 to 200 µAdc, 4 to 20 mAdc, 0 to 10 Vdc, or 1 to 5 Vdc; high impact shock resistant; and watertight or sealed electrical indicating meter types in accordance with one of the following:
(a) 4½ in., 250° with nominal scale length meter;
(b) Panel mounted, edgewise meter;
(c) Digital bargraph-type panel meter with minimum 4-digit display and minimum 51–segment (101–segment preferred) analog display. Light-emitting diode type preferred; and
(d) Digital panel display with 3½ digits graduated 0 to 100% only. Light-emitting diode type preferred.

S7.15.1 Dials—Unless otherwise specified (see S5.2), liquid level display dials shall be furnished blank, except for minimum and maximum travel points. The dial shall be readily removable and replaceable from the front of the liquid level display without disturbing the pointer or other parts of the liquid level display. The dial surface shall be suitable for marking by an installing activity after the liquid level indicating equipment has been calibrated to a particular tank. When graduations are specified, they shall extend uniformly over the full range of the liquid level display and shall be multiples of 1, 2, 5, 10, 20, 50, and so forth. Multiples of any other numbers or fractions are not permitted. The minimum number of graduations per dial shall be 24 and the maximum number of graduations shall be 200. Dials shall begin and end with a numbered graduation. Markings such as “O” and “F” shall not be used. When required (see S5.2), additional information shall be identified on the dial as specified by the contracting activity. Unless otherwise specified (see S5.2), dials shall have black letters, numerals, and gradations on a white background. The indicator pointer shall be black.

S7.15.2 Red Illumination—When red illumination is specified (see S5.2), the primary indicator shall have white letters, numerals, and gradations on a black background and shall
contain internal red illumination. The letters, numerals, and graduations shall appear white under ambient white light and red under ambient and internal red light. The indicator pointer shall be either red illuminated or silhouetted against the dial. Red illuminated dials shall be readable in all levels of incident illumination up to 0.3 lux. The lighting circuit shall be ungrounded and shall be energized from a 6-V supply with separate external terminals.

S7.15.3 Display Visibility—The display shall be clearly visible from a distance of 3 ft and from a viewing angle of 45° from normal, both vertically and horizontally.

S7.16 Audible Signals—When audible signals are required for any remote station (see S5.2), the audible signal shall be actuated by the signal conditioner output or a control circuit adjusted to a predetermined level (see S7.9.1 and S7.9.2).

S8. Performance Requirements

S8.1 Service Life—Electrical liquid level indicating equipment shall be constructed for a life of 25 years of operation.

S8.2 Sensing Device Operation—The sensing device shall not use any part of the tank structure as part of the sensing device.

S8.3, Accuracy

S8.3.1 Liquid Level Indicating Equipment Accuracy—Liquid level indicating equipment accuracy shall be as follows:

(a) Actual liquid level as “height in the tank” or “volume in the tank” (volumetric accuracy), whichever is specified in S5.2, shall be within ±3% of full scale and

(b) Repeatability of the indicators shall be within ±1% of full scale at any point on the scale.

S8.3.2 Control Circuit—Accuracy of adjustable control circuit setpoints shall be as follows:

(a) Hysteresis of dead band make and break of the control function when operated through down and up cycles shall not exceed ±3% including instrument hysteresis and dead band and

(b) Repeatability of the control point contact shall be within ±1% of full scale.

S8.4 Response Time

S8.4.1 Indication Response Time—Liquid level indicating equipment shall have an indication response time of 0.5 s or less for liquid level change rates up to 1 in./s. Indication response time is defined as the time difference between when a liquid achieves a specified level and when the liquid level display indicates that specified level within the accuracy requirements of S8.3.

S8.4.2 Control Circuit Response Time—Control circuit response time shall be adjustable and shall have a minimum control circuit response time of 0.5 s and a maximum control circuit response time of 20 s. The indication response time shall be in accordance with S8.4.1 regardless of control circuit response time setting. Control circuit response time is defined as the time difference between when a liquid reaches a setpoint level and when the control circuit activates or deactivates the switching device associated with that setpoint level. Accuracy shall be in accordance with S8.3.

S8.5 Insulation Resistance—The liquid level indicating equipment insulation resistance shall not be less than 10 MΩ. Accuracy shall be in accordance with S8.3 after measurement of insulation resistance.

S8.6 Specific Gravity—For applications in which the fluid is FO, CO, WO, CF, or JP, accuracy shall be in accordance with S8.3 when subjected to changes in specific gravity. Manual adjustments shall not be permitted or required to obtain accuracy.

S8.7 Fluid Conductivity—For applications in which water of any type is present, accuracy shall be in accordance with S8.3 when the water conductivity is in the range of 3 to 10 000 µS/cm. Manual adjustments shall not be permitted or required to obtain accuracy.

S8.8 Tank Wall Proximity—Accuracy shall be in accordance with S8.3 when the distance from the sensing device to the tank walls is reduced.

S8.9 Inclination—Accuracy shall be in accordance with S8.3 when the liquid level indicating equipment is inclined. Differential pressure sensing devices with ranges less than 20 in. of water may compensate for hydrostatic pressure changes created by the inclined geometry.

S8.10 Spike Voltage—Accuracy shall be in accordance with S8.3 after spike voltage is applied.

S8.11 Accelerated Life (Endurance)—The liquid level indicating equipment shall withstand the effects of the accelerated life test. The temperature range shall be 0 to 60°C except for ST (steam) applications in which the temperature range shall be 0 to 100°C. Performance shall be in accordance with S8.3 throughout the test. After completion of the test and cleaning, the base metal shall not be visible through the finish nor shall there be any evidence of blistering, softening, separation from the base metal, corrosion, or other coating failures. Flexible interconnections shall not exhibit any signs of deterioration nor corrosion of connector pins and housings. Upon completion of the accelerated life tests, accuracy and response time shall be in accordance with S8.3 and S8.4.

S8.11.1 Power Supply—The power supply shall be compatible with Type I power input as specified in MIL-STD-1399, Section 300. Nominal power input voltage and frequency shall be 115 V, 60 Hz, single phase. Changes in input voltage and frequency within ±5% of nominal shall have no deleterious effect on the power supply. Accuracy shall be in accordance with S8.3.

S8.12 Enclosure—Liquid level indicating equipment to be installed partially or totally outside the tank shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures. Portable liquid level indicating equipment shall meet all test criteria in NEMA Standard 250 for Type 6 enclosures. Operation shall be in accordance with S8.3.

S8.13 Pressure—Sensing devices that may be exposed to seawater or the fluid being measured, complete with entrance fittings and interconnection fittings, shall withstand the pressure test without physical or electrical damage and without any leakage or signs of leakage around any of the fittings. Flexible interconnections shall show no evidence of liquid intrusion or evidence of mechanical or electrical damage. Accuracy of all readings shall be in accordance with S8.3 throughout the test and for the postinspection reference measurement.
S8.14  *Vibration*—Liquid level indicating equipment shall show no evidence of mechanical or electrical damage or loosening of pans when subjected to the vibration test. Operating controls shall not change status, and there shall be no transfer of switch contacts during, or as a result of, the vibration test. Accuracy shall be in accordance with S8.3.

S8.15  *Shock*—Liquid level indicating equipment shall show no evidence of mechanical or electrical damage or loosening of pans as a result of shock tests. Operating controls shall not change status, and there shall be no transfer of switch contacts as a result of shock tests. Accuracy shall be in accordance with S8.3.

S8.16  *DC Magnetic Field*—Unless otherwise specified (see S5.2), liquid level indicating equipment shall meet the 400-A/m dc magnetic field environment requirement of MIL-STD-1399, Section 070, Part 1. Accuracy shall be in accordance with S8.3.

S8.17  *Electromagnetic Interference*—The liquid level indicating equipment shall meet the requirements of Table II of MIL-STD-461, except as modified below:

- CE101—The test signal shall be applied only to the ac power leads of the test sample.
- CE 102—The test signal shall be applied only to the ac power leads of the test sample.
- CS114—Only limit Curve #2 shall apply with the frequency range limited to 10 kHz to 30 MHz.
- RE101—Only the limit curve for 50 cm shall apply.
- RS103—The frequency range shall be limited to 10 kHz to 18 GHz with an electric field strength test level of 10 V/m.

Accuracy shall be in accordance with S8.3.

S8.18  *Flexible Interconnection*—Type I cables shall resist swelling and show no evidence of liquid intrusion or evidence of mechanical or electrical damage after immersion testing in JP-5. Removable flexible interconnections shall meet the insulation resistance test requirements of S8.5 after completion of immersion testing.

**S9. Workmanship, Finish, and Appearance**

S9.1  After fabrication, parts and assembled equipment shall be cleaned of smudges; loose, spattered, or excess solder; weld metal; metal chips and mold release agents; or any other foreign material that might detract from the intended operation, function, or appearance of the equipment. Wires and cables shall be positioned or protected to avoid contact with rough or irregular surfaces and sharp edges and to avoid damage to conductors or adjacent parts. There shall be no evidence of burns, abrading, or pinch marks in wire or cable insulation that could cause short circuits or leakage. The clearance between wires or cables and heat generating parts shall be sufficient to minimize deterioration of the wires or cables.

**S10. Inspection**

S10.1  *Classification of Inspections*—The inspection requirements specified herein are classified as follows:

(a) First article tests (see S10.2) and
(b) Conformance tests (see S10.3).

S10.2  *First Article Test*—First article tests shall be performed before production. First article tests shall be performed on samples that have been produced with equipment and procedures normally used in production. First article tests shall consist of the tests specified in Table S10.1. Failure of any liquid level indicating equipment to meet the requirements of this specification shall be cause for rejection.

S10.2.1  *Order of First Article Tests*—With the exception of the immersion test which may be performed at any time, the test specimens (liquid level indicating equipment) shall be subjected to the tests specified in Table S10.1 in the order listed. Any deviation in the test order shall first be approved by the buyer.

S10.3  *Conformance Tests*—Liquid level indicating equipment samples in each lot offered for delivery shall be subjected to the tests listed in Table S10.2 and shall be conducted in the order listed. Failure of any liquid level indicating equipment to meet the requirements of this specification shall be cause for rejection.

S10.4  *General Examination*—Each sample equipment shall be subjected to a general examination to ascertain that the material, parts, testability, input connectors and color code, size and weight, accessibility, workmanship, design, proper cable harness dress, creepage and clearance distances, safety requirements, and treatment for prevention of corrosion are in conformance with this specification. The fit of parts shall be observed with particular reference to the interchangeability of such parts as are likely to require replacement during the normal service life of the equipment. Examination shall also check all controls, adjustments, displays, indicators, liquid level indicating equipment description, mounting devices, signal conditioner, operation, control circuit (including failsafe design), primary indicator panel assembly, auxiliary indicator
S11. Number of Test and Retests

S11.1 One liquid level indicating equipment of each type (that is, sensing technique, application, pressure range, display, and indication range) (see S4.1) shall be subjected to first article testing when specified (see S5.2).

S11.2 An inspection lot for conformance inspection shall consist of all liquid level indicating equipment of each type (that is, sensing technique, application, pressure range, display, and indication range) (see S4.1) produced under the same conditions and offered for inspection at the same time. Sampling and acceptance for Group A and Group B testing shall be as specified (see S5.2). When the number of rejected equipment, in any sample, exceeds the acceptance number for that sample, the lot represented by the sample shall be rejected.

S12. Test Methods

S12.1 Test Conditions—Except where the following factors are the variables, or unless otherwise specified in the individual test procedure, the tests specified in S12.2 shall be conducted with the liquid level indicating equipment operating under the following conditions:

(a) Ambient temperature shall be 23 ± 1.0°C.
(b) Relative humidity shall be 50 ± 5%.
(c) Supply voltage shall be 115 V ± 5%.  
(d) Supply frequency shall be 60 Hz ± 5%.  
(e) Controls shall be in the neutral or normal position.  
(f) Liquid level indicating equipment shall be mounted to simulate shipboard installation and measure the liquid level along the vertical centerline of the test tank (see S12.1.1).  
(g) Liquid level indicating equipment shall be configured to indicate liquid level height over a vertical distance equal to the normal operating range (height) of the sensing device.  
(h) The fluid/gas or fluid/water used shall be the same as the intended application (see S4.3), except that ordinary tap water having a minimum conductivity of 400 µS may be substituted for seawater interface applications. For CF applications, the fluid used for testing shall be JP-5. For CO and WO applications, the fluid used for testing shall be lube oil 2190 in accordance with MIL-L-17331, or equal. For CF/AR and CO/AR applications, the fluid used for testing shall be water having a minimum conductivity of 400 µS with a 3- ± 0.25-in. layer of JP-5 for CF/AR and lube oil 2190 in accordance with MIL-L-17331, or equal, for CO/AR applications.  
(i) The fluid temperature shall be 25 ± 10°C.

S12.1.1 Test Tank—The test tank shall be a carbon steel test tank coated for surface ship seawater tanks. The test tank shall be large enough to exercise the liquid level indicating equipment through the normal operating range (height) of the sensing device for tests specified herein. The tank shall have a sight glass or similar device with sufficient resolution and accuracy to determine the accuracy, repeatability, hysteresis, and dead band requirements of S8.3.

S12.2 Tests—The liquid level indicating equipment and all associated test equipment shall be energized for a period of time sufficient to ensure complete warm-up.

S12.2.1 Reference Measurement—When specified in the individual test, a reference measurement shall consist of measurements of the indicated level versus actual tank level. (When volumetric accuracy is required (see S5.2), the actual tank levels and the indicated levels shall be converted to volumetric levels using the capacity curve supplied by the contracting activity.) The measurements shall be measured at a minimum of ten equal increments, ± ½ % of full scale, for both increasing (upscale) and decreasing (downscale) level. The liquid level shall be maintained at each checkpoint for a time sufficient to obtain a stable measurement, but not longer than 30 s. Reference measurement accuracy shall meet the requirements of S8.3. For fluid/water interface liquid level indicating equipment, the following conditions shall apply:

(a) The tank shall be filled over the entire normal operating range (height) of the sensing device. The tank shall be full of water, full of the measured fluid, or full of some combination of water and the measured fluid.

(b) The liquid level indicating equipment shall indicate 0 % of the sensing device normal operating range (height) when the tank is full of water.

(c) The liquid level indicating equipment shall indicate 100 % of the sensing device normal operating range (height) when the tank is full of the measured fluid.

(d) The two fluids shall not be agitated in any way to create an emulsion. The two fluids shall be allowed to separate and form a distinct interface before any measurements are taken.

S12.2.2 Accuracy

S12.2.2.1 Liquid Level Indicating Equipment Operation and Accuracy—The sensing device shall be conditioned first by raising and lowering the level between 0 and 100 % of the sensing device normal operating range (height) for three consecutive cycles. Three reference measurements (see S12.2.1) shall then be made in succession. Accuracy shall be in accordance with S8.3.

S12.2.2.2 Control Circuit Accuracy—The detection points for the high control circuit setpoints shall be tested at 50, 75, and 98 % of the sensing device normal operating range (height). The detection points for the low control circuit setpoints shall be tested at 2, 25, and 50 % of the sensing device normal operating range (height). The liquid level shall be raised above then lowered below each detection point three successive times. The control circuit accuracy shall be in accordance with S8.3 at each control circuit setpoint tested.

S12.2.3 Response Time Tests—The test tank (see S12.1.1) shall be used to subject the sensing device to changes in liquid level at a constant rate. Where it is impractical to achieve the fill/empty rate specified, this test may be performed by simulating the change in fluid level (for example, raising or lowering the sensing device by means of a pneumatic cylinder) at the same rate specified.

S12.2.3.1 Indication Response Time Test—This test is applicable to all liquid level indicating equipment. When an adjustable response time is provided, the liquid level indicating equipment shall be adjusted to its minimum response time setting. The actual fluid level and the level indicated by the liquid level displays shall be monitored. The test point levels shall be 20, 50, and 80 % of the liquid level indicating
equipment normal operating range (height). The fluid level shall be increased at a constant rate of $1 \pm 0.01$ in./s through the test points and then decreased at the same rate through the test points. The elapsed time from when the actual fluid level reaches a test point level to when the liquid level indication equipment indicates the test point level, within the specified accuracy requirements (see S8.3), shall be measured both upscale and downscale. The maximum elapsed time shall be the indication response time. Performance shall conform to the requirements of S8.4.1.

S12.2.3.2 Control Circuit Response Time Test—This test is applicable only to liquid level indicating equipment with control circuit(s). When two high control circuits are provided, one setpoint shall be set at 50 % and one at 80 % of the liquid level indicating equipment normal operating range (height). When two low control circuits are provided, one setpoint shall be set at 20 % and one at 50 % of the liquid level indicating equipment normal operating range (height). When one high and one low control circuit is provided, their setpoints shall be set at 80 and 20 % of the liquid level indicating equipment normal operating range (height), respectively.

S12.2.3.2.1 Minimum Control Circuit Response Time Test—The control circuit shall be adjusted to its minimum response time setting. The fluid level shall be increased at a constant rate of $1 \pm 0.01$ in./s through the test points and then decreased at the same rate through the test points. The elapsed time from when the actual fluid level reaches a test point level to when the control circuit activates or deactivates the switching device associated with that setpoint level shall be measured both upscale and downscale. The maximum elapsed time shall be the minimum control circuit response time. Performance shall conform to the requirements of S8.4.2. This test may be done concurrently with S12.2.3.1.

S12.2.3.2.2 Maximum Control Circuit Response Time Test—The control circuit shall be adjusted to its maximum response time setting. The fluid level shall be increased at a constant rate of $0.25 + 0.005$ in./s through the test points and then decreased at the same rate through the test points. The elapsed time from when the actual fluid level reaches a test point level to when the control circuit activates or deactivates the switching device associated with that setpoint level and the elapsed time from when the actual fluid level reaches a test point level to when the liquid level indication equipment indicates the test point level within the specified accuracy requirements (see S8.4.2) shall be measured both upscale and downscale. The maximum elapsed time between when the actual fluid level reaches a test point level to when the control circuit activates or deactivates the switching device associated with that setpoint level shall be the maximum control circuit response time. The maximum elapsed time between when the actual fluid level reaches a test point level to when the liquid level indication equipment indicates the test point level within the specified accuracy requirements (see S8.4.2) shall be the indication response time. Performance shall conform to the requirements of S8.4.2.

S12.2.4 Insulation Resistance Test—The insulation resistance of the liquid level indicating equipment shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The insulation resistance measurement shall be made immediately after a 2-min period of uninterrupted test voltage application. However, if the indication of insulation resistance meets the specified limit (S8.5) and is steady or increasing, the test may be terminated before the end of the 2-min period. The accuracy test (see S12.2.2) shall be performed after completion of the insulation resistance measurements. Performance shall conform to the requirements of S8.5.

S12.2.5 Specific Gravity Test

S12.2.5.1 Fluid/Gas Interface Test—This test applies only to fluid/gas interface applications in which the fluid is FO, CO, WO, CF, or JP. Two accuracy tests (see S12.2.2) shall be performed, one using water as the test fluid and the other using an organic fluid with a specific gravity of 0.86 ± 0.02, such as lube oil. The liquid level indicating equipment shall not be altered, modified, or manually adjusted during each accuracy test or between the two accuracy tests. Performance shall conform to the requirements of S8.6.

S12.2.5.2 Fluid/Water Interface Test—This test applies only to fluid/water interface applications in which the fluid is FO, CO, WO, CF, or JP. Two accuracy tests (see S12.2.2) shall be performed, the first using water and an organic fluid with a specific gravity of 0.86 ± 0.02, such as lube oil as the test fluids, and the second using water and another fluid with a specific gravity of 0.78 ± 0.02, such as kerosene, as the test fluids. The liquid level indicating equipment shall not be altered, modified, or manually adjusted during each accuracy test or between the two accuracy tests. Performance shall conform to the requirements of S8.6.

S12.2.6 Fluid Conductivity Test—This test applies only to SW, FW, WW, CO, CF, and WO applications. Three accuracy tests (see S12.2.2) shall be performed using water with a different electrical conductivity for each test. The three test conductivities of water shall be 3 ± 2, 500 ± 50, and 10 000 ± 50 µS/cm. The conductivity of the water shall be controlled by varying the concentration of sodium chloride in solution with the water. The liquid level indicating equipment shall not be altered, modified, or manually adjusted during each accuracy test or between the accuracy tests. Performance shall conform to the requirements of S8.7.

S12.2.7 Tank Wall Proximity Test—The sensing device shall be located at a corner of the test tank that is formed by two continuous steel walls and shall be equidistant from each of the two adjoining walls. The distance to each wall shall either provide 1 in. of clearance between the sensing device and the wall or shall be the minimum distance specified by the manufacturer up to a maximum of 4 in. An accuracy test (see S12.2.2) shall be performed. Performance shall conform to the requirements of S8.8.

S12.2.8 Inclination—The accuracy test (see S12.2.2) shall be performed except that the liquid level indicating equipment and the test tank shall be inclined 45°, unless otherwise specified (see S5.2), to each side of vertical along both the fore-and-aft and athwartship axes of the tank, for a total of four positions. Reference measurements (see S12.2.1) shall be taken in each of the four inclined positions. The actual liquid level
shall be measured at the inclined vertical tank centerline. Performance shall conform to the requirements of S8.9.

S12.2.9 Spike Voltage Test—The liquid level indicating equipment shall be subjected to an input supply line voltage spike of 2500-V positive peak amplitude; the voltage waveform shall be in accordance with MIL-STD-1399, Section 300, Fig. 2. Voltage Spike Impulse Wave Shape. This spike shall be impressed at normal supply line voltage and frequency while the liquid level indicating equipment is operating. The accuracy test (see S12.2.2) shall be performed at the conclusion of the test. Performance shall conform to the requirements of S8.10.

S12.2.10 Accelerated Life Test—Liquid level indicating equipment shall be subjected to the accelerated life test as specified herein. Throughout the test, the temperature of the fluid in the test tank shall be within plus or minus 5°C of the required test chamber temperature. The liquid level in the tank shall be continuously cycled from empty to full throughout the test. If the test tank is sealed from the ambient environment, the humidity inside the test tank need not meet the test chamber humidity requirements. Performance shall conform to the requirements of S8.11.

S12.2.10.1 Initial Test Conditions—The test shall begin with the following initial conditions:
(a) Equipment set up in a temperature-controlled chamber at 25 ± 5°C and relative humidity of 90 to 100 %.
(b) Equipment energized.
1—Nominal line voltage of 115 V ± 5 % and nominal frequency of 60 Hz ± 5 %.
2—Fully operational for 2 h.
(c) When equipment internal temperature has stabilized, performance parameters shall be measured as reference test data for comparison with subsequent tests.

S12.2.10.2 Temperature Conditions—After initial test conditions have been satisfied, temperature testing shall be performed as follows:
(a) Reduce chamber temperature, at a uniform rate in not less than 4 h, to the lowest operating temperature of the range specified and maintain relative humidity of 90 to 100 %.
(b) Maintain chamber temperature at the lowest operating temperature of the range for 4 h.
(c) Near the end of the fourth hour, measure performance parameters specified in S8.12.
(d) Increase chamber temperature, at a uniform rate in not less than 6 h, to the highest operating temperature of the range specified and maintain humidity at 90 to 100 %.
(e) Maintain chamber temperature at the highest operating temperature of the range specified for 4 h.
(f) Near the end of the fourth hour, measure performance parameters specified in S8.12.
(g) Reduce chamber temperature, at a uniform rate in not less than 6 h, to the lowest operating temperature of the range specified and maintain humidity at 90 to 100 %.
(h) Maintain chamber temperature at the lowest operating temperature of the range specified for 2 h.

S12.2.10.3 Voltage and Frequency Cycling Conditions—After completion of the 2-h low-temperature conditioning period specified in S12.2.10.2(h), perform the following:
(a) Decrease the input voltage to the lowest limit of the equipment voltage tolerance band.
(b) Maintain chamber temperature at the lowest operating temperature and input voltage at the lowest limit for 1 h while equipment continues to operate, then measure performance parameters specified in S8.11.
(c) Return input voltage to nominal value. Decrease input frequency to the lower limit of the equipment frequency tolerance band.
(d) Maintain chamber temperature at the lowest operating temperature and input frequency at the lowest limit for 1 h while equipment continues to operate, then measure performance parameters specified in S8.11.
(e) Return input frequency to nominal value.
(f) Increase temperature to 25 ± 5°C and maintain relative humidity at 90 to 100 %. Maintain this condition for 2 h.
(g) With equipment operating at 25 ± 5°C and relative humidity at 90 to 100 %, decrease input voltage and frequency to the lower limits of the equipment voltage and frequency tolerance bands. Maintain this condition for 1 h and then measure performance parameters specified in S8.11.
(h) Repeat S12.2.10.3(g) with input voltage at the upper limit of the equipment voltage tolerance band and input frequency at the lower limit of the equipment frequency tolerance band.
(i) Repeat S12.2.10.3(g) with input voltage and frequency at the upper limits of the equipment voltage and frequency tolerance bands.
(j) Repeat S12.2.10.3(g) with input voltage at the lower limit of the equipment voltage tolerance band and input frequency at the upper limit of the equipment frequency tolerance band.
(k) Repeat uniform temperature rise test of S12.2.10.2(d).
(l) Measure performance parameters specified in S8.12 at the end of the uniform temperature rise test of S12.2.10.3(k).
(m) With equipment operating at the highest operating temperature of the range specified and relative humidity at 90 to 100 %, increase input voltage to the upper limit of the equipment voltage tolerance band, maintaining input frequency at the upper limit of the equipment frequency tolerance band.
(n) Operate for 4 h at this condition and measure performance parameters specified in S8.11.
(o) Maintain input frequency at the upper limit of the equipment frequency tolerance band but decrease input voltage to the lower limit of the equipment voltage tolerance band.
(p) Operate for 1 h at this condition and measure performance parameters specified in S8.11.
(q) Maintain high temperature and humidity conditions but return input voltage and frequency to nominal values.
(r) Operate for 1 h at this condition and measure performance parameters specified in S8.11.
(s) Reduce temperature to 25 ± 5°C and maintain relative humidity at 90 to 100 %. Maintain this condition for 2 h.
(t) Repeat temperature, voltage, and frequency cycling tests of S12.2.10.3(g) through (s) with relative humidity at 90 to 100 % for not less than eight cycles.
(u) Repeat uniform temperature rise test of S12.2.10.2(d).
(v) Repeat temperature, voltage, and frequency cycling tests of S12.2.10.3(m) through (r) with relative humidity at 10 to 20 % for not less than ten cycles.
(w) Reduce chamber temperature, at a uniform rate in not less than 6 h, reduce relative humidity to 45 to 55 % and return temperature, voltage, and frequency to nominal values specified in S12.2.10.1.

(x) Operate for 2 h at this condition and perform accuracy (see S12.2.2) and response time (see S12.2.3) tests.

S12.2.11 Enclosure Test—Each liquid level indicating equipment enclosure to be installed partially or totally outside the tank shall be subjected to the tests in NEMA Standard 250 for Type 4X enclosures. The portable indicator assembly shall be subjected to the tests in NEMA Standard 250 for Type 6 enclosures. Performance shall conform to the requirements of S8.12.

S12.2.12 Pressure Test—The components of the liquid level indicating equipment, including flexible interconnections, subject to immersion in the measured fluid, shall be installed in a pressure vessel to simulate actual tank installation so that all parts of the components, especially connections and fittings, are submerged and remain submerged except when test conditions state otherwise. Before testing, the pressure vessel with the liquid level indicating equipment installed shall be filled and allowed to soak for 1 h at atmospheric pressure. Except for the AP pressure range (see S4.4), the rate of pressure change shall not be less than 10 lb/in.²·s. For the AP pressure range, the rate of pressure change shall not be less than 5 lb/in.²·s.

S12.2.12.1 Pressure Test Procedure—The pressure test shall consist of three successive fill and empty cycles. The pressure vessel shall be filled in ten equal increments through the sensing device normal operating range (height) at atmospheric pressure and level readings taken at each increment. The specified pressure (see below) shall then be applied and held for 1 h. While maintaining the specified pressure with compressed gas, the pressure vessel shall be emptied in ten equal increments and level readings shall be taken at each increment. The pressure shall then be reduced to atmospheric for 10 min and the cycle repeated twice. During the third pressure cycle, an insulation resistance measurement (see S12.2.4) shall be made on the sensing device at both the specified pressure and at atmospheric pressure. The specified pressure for the test shall be as follows:

(a) AP pressure range sensing devices shall be subjected to 30 psig.
(b) VP and LP pressure range sensing devices shall be subjected to 150 psig.
(c) HP pressure range sensing devices shall be subjected to 150 % of the maximum pressure specified (see S5.2).

S12.2.12.2 Posttest Inspection—Upon completion, the sensing device shall then be removed from the pressure vessel and disassembled to the maximum extent possible without affecting sensing device performance or integrity. The sensing device shall be examined for any physical or electrical damage and leakage or signs of leakage. The sensing device shall then be reassembled and a reference measurement (see S12.2.1) taken. Performance shall conform to the requirements of S8.13.

S12.2.13 Vibration Test—Liquid level indicating equipment shall be tested in accordance with Type I (environmental) vibration of MIL-STD-167-1. Components of the liquid level indicating equipment, including sensing devices, shall be mounted to simulate shipboard installations in an empty tank and shall not be restricted from normal operation and movement. The equipment under test shall be energized in the normal manner. At the conclusion of the test and before any adjustments, accuracy shall be measured (see S12.2.2). Liquid level indicating equipment shall be physically examined for evidence of mechanical or electrical damage or loosening of parts. Performance shall conform to the requirements of S8.14.

S12.2.14 Shock Test—Liquid level indicating equipment shall be tested in accordance with Grade A, Class 1, Type A equipment as specified in MIL-STD-624. The liquid level indicating equipment shall be energized in the normal manner. Components of the liquid level indicating equipment, including sensing devices, shall be mounted to simulate shipboard installation in an empty tank and shall not be restricted from normal operation and movement. If individual components of the liquid level indicating equipment must be shock tested separately because of size or weight, the complete liquid level indicating equipment shall be connected together (electrically and mechanically) as designed, energized, and the output and control circuit signals monitored during the test. At the conclusion of the test and before any adjustments, the accuracy shall be measured as specified in S12.2.2. The liquid level indicating equipment shall be physically examined for evidence of mechanical or electrical damage or loosening of parts. Performance shall conform to the requirements of S8.15.

S12.2.15 DC Magnetic Field—The liquid level indicating equipment shall be tested in accordance with MIL-STD-1399, Section 070, Part 1. Unless otherwise specified (see S5.2), the magnetic field strength shall be 400 A/m. Performance shall conform to the requirements of S8.16.

S12.2.16 Electromagnetic Interference Tests—EMI tests shall be in accordance with the test methods specified in MIL-STD-461, with the modifications as specified in S8.17. Upon completion of the EMI tests, an accuracy test (see S12.2.2) shall be performed. Performance shall conform with the requirements of S8.17.

S12.2.17 Flexible Interconnection Immersion Test—When intended for use in tanks containing CF, CO, WO, FO, or JP type fuels, flexible interconnections shall be submerged in JP5 for a continuous period of 45 days. The test fluid temperature shall be maintained at 25 ± 10°C. Removable flexible interconnections may be tested with a simulated shipboard installation using test fixtures to replace sensing devices. After completion of immersion testing, the flexible interconnection shall undergo a physical examination and insulation resistance test (see S12.2.4). Performance shall conform to the requirements of S8.18.

S12.2.18 Supply Line Voltage and Frequency Variation—Liquid level indicating equipment shall be operated at normal, maximum, and minimum steady state voltages and frequencies (see S8.11.1). The liquid level indicating equipment shall remain at each configuration for 15 min. A reference measurement (see S12.2.1) shall be performed before and after each transition. Performance shall conform to the requirements of S8.11.1.
S13. Certification

S13.1 The purchase order or contract should specify whether the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. The purchase order or contract should specify when a report of the test results shall be furnished. Otherwise, the purchase order or contract should specify that all test data remain on file for three years at the manufacturer’s facility for review by buyer upon request.

S14. Product Marking

S14.1 Marking—Unless otherwise specified (see S5.2), all major liquid level indicating equipment components shall be marked or provided with label plates. Markings on plastic or metallic materials shall be made by stamping, engraving, stenciling, or rubber-stamping with smudgeproof ink covered with a coat of clear lacquer or silk screening. Label plates shall be made with engraved or stamped markings. At a minimum, labels and markings shall contain:

(a) “LIQUID LEVEL INDICATOR,”
(b) Component name,
(c) Manufacturer’s name,
(d) National Stock Number (NSN), if available,
(e) Date of manufacture, and
(f) Designation (see S4.1).

A label plate marked with manufacturer’s part number and serial number shall be permanently affixed on the front of each indicator panel assembly.

S15. Packaging and Package Marking

S15.1 Packaging and package marking shall be in accordance with Section 15.

S16. Quality Assurance

S16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see S5.2).

S16.2 Warranty—Any special warranty requirements shall be specified in the acquisition requirements (see S5.2).
1. Scope

1.1 This specification covers the requirements for direct and indirect reading sight liquid level indicators for general applications. General applications for indirect reading sight glasses are water and fuel service at working pressures 2.07 MPa (300 lb/in.2) and below, temperatures of 149°C (300°F) and below. General applications for direct reading sight glasses are applications in which the temperature does not exceed 66°C (150°F).

1.2 Direct reading sight glass indicators may consist of glass or plastic tubes with fittings including shutoff valves. Glass tubes may be used for low shock direct reading sight glass indicators in which the fluid is not compatible with plastic.

1.3 Indirect reading indicators may consist of a sealed chamber with a magnetic float or flag indicator.

1.4 Special requirements for naval shipboard applications are included in the supplement to this standard.

1.5 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:
D 3951 Practice for Commercial Packaging

2.2 ANSI Standards:
B16.5 Pipe Flanges and Flanged Fittings (DoD adopted)

3. Terminology

3.1 Definitions:
3.1.1 SI (Le Systeme International d’Unites) Units—units of measurement recognized by the CIPM (Comite International des Poids et Mesures).

4. Design Classification

4.1 Types—Indicator designs are classified as either direct reading or indirect reading. Both types are depicted in Fig. 1, complete with dimensions that facilitate ordering.

4.2 Special Considerations—Special considerations that may affect selection and installation are listed below. This is not to be construed as a complete listing.

(a) Type of indicator,
(b) Manual or automatic shutoff valves,
(c) Indication length of liquid level range,
(d) Method of connection,
(e) Location of indicator relative to vibrating equipment,
(f) Protection of the instrumentation,
(g) Application of each indicator,
(h) Cleaning procedure or reference to the cleaning procedure being used, and
(i) Selection of indicator for compatibility with materials, temperature, pressure, ambient environment, and with the parameter being measured.

5. Ordering Information

5.1 The buyer shall provide the manufacturer with all of the pertinent application data outlined in the acquisition requirements.

5.2 Acquisition Requirements—Acquisition documents shall specify the following:

(a) Title, number, and date of this specification;
(b) Type and quantity of indicators required;
(c) Manufacturer’s part number;
(d) When qualification testing is required;
(e) Final disposition of qualification test samples;
(f) Environmental requirements;
(g) Operating media;
(h) Viscosity and specific gravity of fluid for indirect indicators;
(i) Materials;
(j) Indication length;
(k) Size and type of connections;
(l) Shutoff valve requirements;
(m) Cleaning requirements;
(n) When certification is required;
(o) Marking requirements;
(p) Unique packaging requirements; and
(q) Unique preservation requirements.

6. Materials and Manufacture

6.1 Materials—The materials for all wetted parts shall be selected for long-term compatibility with the process medium and ambient conditions.

6.2 Material Inspection—The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with the specifications and standards as applicable.

6.3 Gaskets and O-Rings—Gaskets and O-rings shall be fabricated of materials suitable to the operating pressure, temperature, and process medium for each application.

7. Physical Properties

7.1 Connections—Sight indicators are usually installed using standard pipe fittings or flanges. Pipe fittings and material should match that of the existing pipe for each installation. Type and size of fittings shall be specified in the acquisition requirements. Welding or brazing shall be performed in accordance with industry standards.

7.2 Flanged Connections—Where sight indicators are installed using flanges, flanges shall be in accordance with ANSI B16.5. Standard flange sizes include 1.27 cm (½ in.), 1.9 cm (¾ in.), 2.54 cm (1 in.), 3.8 cm (1-½ in.), and 5.08 cm (2 in.). Standard flange pressure ratings include 1.034 MPa (150 psi), 2.07 MPa (300 psi), and 4.14 MPa (600 psi). Other flange requirements shall be specified in the acquisition requirements.

7.3 Vent and Drain Connections—Where required, vent and drain connections are usually plugged, ½- or ¾-in. NPT or

FIG. 1 Indicator Design Types
with NPT valves. Other vent and drain connections shall be specified in the acquisition requirements.

8. Performance Requirements

8.1 Performance Considerations—In many applications, certain performance characteristics are deemed critical to the intended or desired function of a sight liquid level indicator. The following are prime examples:
   (a) Accuracy,
   (b) Shock and vibration classifications, and
   (c) Operating pressure and temperature ranges.

9. Workmanship, Finish, and Appearance

9.1 Finish and Appearance—Any special surface finish and appearance requirements shall be specified in the acquisition requirements.

9.2 Sight Glass Cleaning—Any special cleaning requirements shall be specified in the acquisition requirements.

10. Inspection

10.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:
   (a) Qualification testing and
   (b) Quality conformance testing.

10.2 Qualification Testing—Qualification test requirements shall be specified where applicable. Qualification test methods should be identified for each design and performance characteristic specified. Test report documentation requirements should also be specified.

10.3 Quality Conformance Testing—Quality conformance testing is accomplished when qualification testing was satisfied by a previous acquisition or product has demonstrated reliability in similar applications. Quality conformance testing is usually less intensive than qualification, often verifying that samples of a production lot meet a few critical performance requirements.

11. Number of Tests and Retests

11.1 Test Specimen—The number of test specimens to be subjected to qualification testing shall depend on the design. If each range is covered by a separate and distinct design, a test specimen for each range will require testing. In instances in which a singular design series may cover multiple ranges and types, only three test specimens need be tested provided the physical similarities are approved by the buyer. In no case, however, shall less than three units, one unit each representing low, medium, and high ranges, be tested, regardless of design similarity.

12. Test Methods

12.1 Tests—All tests shall be performed in accordance with ASTM, ASME, or industry standards as specified.

12.2 Test Data—All test data shall remain on file at the manufacturer’s facility for review by the buyer upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years or a period of time acceptable to the buyer and manufacturer.

13.1 Warranty—Unless otherwise specified, the manufacturer is responsible for the following:
   (a) All materials used to produce a unit and
   (b) Manufacturer will warrant his product to be free from defect of workmanship to produce the unit.

14. Certification

14.1 When specified in the purchase order or contract, the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

15. Product Marking

15.1 User-specified product marking shall be listed in the acquisition requirements.

16. Packaging and Package Marking

16.1 Packaging of Product for Delivery—Product shall be packaged for shipment in accordance with Practice D 3951.

16.2 Any special preservation, packaging, or package marking requirements for shipment or storage shall be identified in the acquisition requirements.

17. Keywords

17.1 direct level indicator; indirect level indicator; liquid level indicator; sight glass
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard (Specification F 2045) and this supplement, the requirements of this supplement shall take precedence for equipment acquired by this supplement. This document supersedes MIL-I-20037, Indicators, Sight, Liquid Level, Direct/Indirect Reading, Tubular Glass/Plastic, for new ship construction.

INDICATORS, SIGHT, LIQUID LEVEL, DIRECT AND INDIRECT READING, TUBULAR GLASS/PLASTIC (NAVAL SHIPBOARD USE)

S1. Scope

S1.1 This supplement covers sight liquid level indicators of the direct and indirect reading type having tubular glass, clear polycarbonate, or rigid polyvinyl chloride (PVC).

S1.2 Direct reading sight glass indicators may consist of glass or plastic tubes with fittings including shutoff valves. Indirect reading indicators may consist of a sealed chamber with a magnetic float or flag indicator.

S1.3 Indirect indicators are intended for use in water and fuel service at working pressures of 2.07 MPa (300 lb/in.²) and below, temperatures of 149°C (300°F) and below, and for hi-shock applications. Direct indicators are intended for use in hi-shock applications and shall use plastic sight tubes where the fluid is compatible and temperatures do not exceed 66°C (150°F). Glass tubes shall only be used for low shock applications and where the fluid is not compatible with plastic tubes.

S1.4 Only direct-type indicators with glass tube material less than 92 cm (36 in.) in length or indirect type indicators shall be used for hydrocarbons and flammable fluid applications.

S3. Terminology

S3.1 Definitions:

S3.1.1 direct indication—the tank fluid level is visible in the glass or tube.

S3.1.2 indirect indication—the tank fluid level is contained in a sealed chamber and indicated by some other means such as a float or flag actuated by a magnet contained in a float in the fluid chamber.

S4. Design Classification

S4.1 Designation—Sight glass indicator designation shall consist of a series of designations which shall be assigned and listed in the format below:

Example: F 2045-SGI-D-A-PLY-PA

<table>
<thead>
<tr>
<th>Specification</th>
<th>Equipment Designator</th>
<th>Indication</th>
<th>Shutoff Valve</th>

<td>(see S4.3)</td>
<td>(see S4.4)</td>
<td>(see S4.5)</td>
<td>(see S4.6)</td>
</tr>
</tbody>
</table>

S4.2 Equipment Designator—The level indicator shall be designated as SGI—Sight Glass Indicator.

S4.3 Indication—The type of indication desired shall be specified as follows:

D—Direct indication
I—Indirect indication

S4.4 Shutoff Valves—The sight glass indicators shall be equipped with a manual or automatic shutoff valve of the ball-check type depending on the type of indication specified. Valve type shall be designated as:

A—Automatic for direct indication
M—Manual for indirect indication

S4.5 Sight Glass Material—The tube material of direct reading sight glass indicators shall be designated as follows:

GWT—Glass with teflon heat shrink tube
PLY—Polycarbonate
PVC—Rigid polyvinyl chloride

S4.6 Application—The sight glass indicators may be used, but are not limited to, the following applications:

LA—Lubricating oil and air interface
PA—Potable water and air interface
DA—Diesel oil and air interface
JA—JP fuel and air interface
FT—Deaerating feed tanks
FA—Feed water and air interface
AG—Aviation gasoline
3F—Aqueous film-forming fluid

S5. Ordering Information

S5.1 The buyer shall provide the manufacturer with all of the pertinent application data shown in accordance with S5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S5.2 Acquisition Requirements—Acquisition documents shall specify the following:

(a) Title, number, and date of this specification;
(b) Quantity and designation of indicator;
(c) Size of connection if specified;
(d) Handwheel with chain when required;
(e) Dimensions, as applicable (see Fig. 1);
(f) Operating temperature, minimum and maximum;
(g) Operating pressure, normal and maximum;
(h) Operating media;
(i) Viscosity and specific gravity of fluid for indirect indicators only;
(j) When qualification testing is required;
(k) Final disposition of qualification test samples;
(l) National Stock Number (NSN) if available;
(m) Unique product marking requirements; and
(n) Unique packaging requirements.

S6. Materials and Manufacture

Piping material used in the construction of sight glass indicators shall be compatible with the intended service piping and media. Material for indirect indicators using a magnetic operating principle shall be corrosion-resistant steel in accordance with Type 304 of Specification A 312. Only direct-type indicators with glass tube material less than 91.44 cm (36 in.) in length or indirect-type indicators shall be used for hydrocarbon and flammable fluid applications.

S6.1 Castings—The composition of castings shall be in accordance with Specifications B 61 or B 62.

S6.2 Forgings—The composition of forgings shall be in accordance with Alloy 632M of Specification B 283.

S6.3 Welding—Welding and nondestructive testing shall be in accordance with NAVSEA Publication S9074-AR-GIB-010/278. In no case shall such processes as peening or plugging be used on castings or forgings for reclaiming any parts.

S6.4 Glass—Glass tubing shall be of annealed borosilicate transparent glass with a 1.59-cm (5/8-in.) outside diameter (o.d.) and a minimum wall thickness of 0.24 cm (3/32 in.) with a transparent fluorinated ethylene propylene plastic insulating sleeving heat shrunk over the glass tube. Glass tubes shall be used for temperatures above 66°C (150°F) but not to exceed 132°C (270°F) or where the fluid is not compatible with polycarbonate or rigid PVC. Maximum length of glass tubes shall be as specified in Drawing 803-5184222.

S6.5 Plastics—Plastics used in the sight glass indicator shall be polycarbonate in accordance with Specification D 3935 or rigid PVC in accordance with Specification D 1784.

S6.6 Recovered Materials—Unless otherwise specified herein, all equipment, material, and articles incorporated in the products covered by this specification shall be new and shall be fabricated using materials produced from recovered materials to the maximum extent practicable without jeopardizing intended use. The term “recovered materials” means materials that have been collected or recovered from solid waste and reprocessed to become a source of raw materials as opposed to virgin raw materials. None of the above shall be interpreted to mean that the use of used or rebuilt products is allowed under this specification unless specified.

S7. Physical Properties

S7.1 Design and Construction—The indicators shall be constructed so as to allow replacement of the glass tube or indicating element and also allow cleaning from either end without loosening any packing or sealing material while the pressure vessel is under pressure.

S7.1.1 Sizes—Unless otherwise specified in the acquisition requirements, the connections of direct indicators shall be of the size specified for the diameter of the tube in accordance with Table S7.1.

<table>

</tbody>
</table>

S7.1.2 Valves:
S7.1.2.1 Nonautomatic Shutoff—The nonautomatic shutoff valve shall be in accordance with MSS SP-72 or MSS SP-110.

S7.1.2.2 Automatic Shutoff—Direct indicators shall have an automatic shutoff valve of the solid ball-check type in accordance with Drawing 803-5184222. The check valve shall be constructed so as to allow leakage of 5 to 25 cm³ per minute at 345 kPa (50 lb/in.²) when the check valve is in the closed position.

S7.1.2.3 Handwheel—When required for remote operation, the shutoff valves shall be furnished with a handwheel having an o.d. not less than 8.89 cm (3 ½ in.) and with holes drilled in the rim located for adapting to chain operation. When specified in the acquisition requirements, chain shall be provided.

S7.1.2.4 Glands—Glands for direct reading gage glasses shall be designed to minimize torsional stress on the glass when the gland is tightened.

S7.2 Protection:

S7.2.1 Class A—The glass tube of direct indicators shall be protected from damage by not less than four solid rods of corrosion-resistant material a minimum of 0.64 cm (1/4 in.) in diameter of sufficient length to allow for a maximum 91.44-cm (36-in.) tube length. A shield shall be provided in accordance with Drawing S8700-1385802 for combustible fluids.

S7.2.2 Class B—Where all plastic sight tubes are used, protective rods or shields are not required. Protective rods or shields shall not be required for indirect indicators.

S7.3 Connections—Sight glass indicators shall have flat-faced ranged connections. Flanges shall be 1.91 cm (¾ in.) in accordance with the dimensions of ANSI B16.5 classes. The flange rating shall be compatible with the maximum pressure and temperature conditions expected in the intended application and shall be based upon the ratio of the allowable stress at temperature of the material used to that for the material specified in ANSI B16.5.

S7.3.1 Drain Connections—The indicators shall have a drain connection to which a drain line may be connected. For pressures below 345 kPa (50 lb/in.²), the drain line connection shall be ¾-in. NPT or larger. For pressures of 345 kPa (50 lb/in.²) or above, the drain line connection shall be a welded socket pipe nipple, ½-in. NPS or larger.

S7.4 Temperature—Direct reading indicators using plastic tubes shall not be used in applications above 66°C (150°F). Glass tubes shall be used for temperatures above 66°C (150°F) but not to exceed 132°C (270°F). Indirect reading indicators using flags in the indicator may be used up to 149°C (300°F) with plastic flags and 232°C (450°F) with aluminum flags.

S7.5 Working Pressure:

S7.5.1 Direct Indicators—Maximum working pressure for direct indicators shall be as specified on Drawing 803-5184222.

S7.5.2 Indirect Indicators—Maximum working pressure for indirect indicators shall be 2.07 MPa (300 lb/in.²) at 149°C (300°F).

S7.6 Interchangeability—Parts, components, and attachments shall be interchangeable with parts and components of the same types and classes produced by the same contractor.

S8. Performance

S8.1 Accuracy:  

S8.1.1 Direct Indicator Accuracy—Accuracy of direct indicator shall be within ±1.27 cm (½ in.).  

S8.1.2 Indirect Indicator Accuracy—Accuracy of the indirect indicator shall be within ±2.54 cm (1 in.). In addition, when indirect indicators are capable of providing a remote indication, the remote indication shall be accurate to within ±3% of full scale.

S8.2 Hydrostatic Effects—Each indirect sight glass indicator shall be capable of withstanding a hydrostatic pressure of 3.1 MPa (450 lb/in.²) when tested in accordance with S12.2.2.1. Each direct sight glass indicator shall be capable of withstanding a hydrostatic pressure of 3.1 MPa (450 lb/in.²) when tested in accordance with S12.2.2.3.

S8.3 Inclination—The indirect sight glass indicator shall provide accurate operation when inclined up to a 45° in any direction and tested as specified in S12.2.3.

S8.4 Salt Spray—The sight glass indicator shall provide accurate operation in a salt spray marine environment when tested as specified in S12.2.4.

S8.5 Reliability—The sight glass indicator shall operate reliably in a naval shipboard environment for a service life of at least 40 000 h. The sight glass indicator shall be mechanically reliable for operating at least 2000-h mean time between failures at a 90% confidence level. A failure is any malfunction that requires unscheduled corrective maintenance of more than 1 h or which requires replacement of the equipment. The reliability of the sight glass indicator shall be demonstrated in accordance with S12.2.5.

S8.6 Shock—The indicator shall show no signs of damage when exposed to Grade A, Class I shock for indirect indicators and Grade B for direct indicators in accordance with MIL-S-901 as specified in S12.2.6.

S8.7 Vibration—The indicator shall show no signs of damage when exposed to Type I vibration in accordance with MIL-STD-167-1 as specified in S12.2.7.

S9. Workmanship, Finish, and Appearance

S9.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, and machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids, and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change as a result of heat from welding operation. There shall be no damage to adjacent parts resulting from welding.

S10. Inspection

S10.1 Inspection System—The testing set forth in this specification shall become a part of the manufacturer’s overall inspection system or quality program. The manufacturer’s quality system shall comply with the requirements of ANSI/ASQC 9001-1994, Quality Systems—Model for Quality Assurance in Design, Development, Production, Installation, and Servicing. Certification and registration is highly desired but not required.

S10.2 Classification of Inspections—The inspection requirements specified herein are classified as follows:
(a) Qualification testing and
(b) Quality conformance testing.

S10.3 Qualification Testing—Qualification testing shall consist of two samples of each type indicator subjected to the examinations and tests in accordance with Table S10.1 in the order shown. Failure of any sight glass indicator to meet the requirements of this specification shall be cause for rejection.

S10.4 Quality Conformance Testing—Sight glass indicators that are produced on the same facilities, using identical materials, manufacturing, and assembly procedures shall be subjected to the quality conformance tests specified in Table S10.1. Sight glass indicators of the same type, class, and size offered for delivery at one time shall be considered a lot for purposes of inspections and tests.

S11. Number of Tests and Retests

S11.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S12. Test Methods

S12.1 General Examination—Sight glass indicators shall be given a thorough examination to determine that it conforms to this specification and the approved drawings with respect to material, finish, construction, assembly, dimensions, workmanship, marking, identification, and information plates.

S12.2 Test Methods:

S12.2.1 Accuracy—Indicator accuracy shall be determined by mounting the indicator assembly to a test tank with a capacity at least 10 % greater than the total indication at the indicator. The tank shall be filled to the zero point of the indicator and in 10 % increments until the maximum level of the indicator is reached. Measurements of the actual fluid level of the tank shall be compared to level shown on the indicator. Indicator accuracy shall be in accordance with S8.1.

S12.2.2 Hydrostatic Tests—Sight glass indicators shall be tested at ambient conditions as a complete assembly for strength and porosity. With the shutoff valves in the open position, a pressure of 3.1 MPa (450 lb/in.²) shall be applied for 20 min. Any weeping, porosity, or deformation shall be cause for rejection. Indicators having plastic sight tubes shall have no permanent deformation of the tube upon release of the test pressure. Upon completion of the test, the pressure shall be reduced to 2.07 MPa (300 lb/in.²) and the valve shall be checked for closing readily against the maximum working pressure of the indicator. The valve shall operate with a maximum force of 13.6 kg (30 lbs).

S12.2.3 Inclination Test—Indirect indicators shall be tested inclined at 45° forward, backward, left, and right. The fluid level shall be varied between 20 to 80 % indication to verify satisfactory operation.

S12.2.4 Salt Spray—The complete indicator assembly and shutoff valves shall be subjected to a salt spray in accordance with Test Method B 117. No appreciable corrosion or other damage shall be evident after exposure to the salt spray.

S12.2.5 Reliability—Reliability of the assembled indicator shall be demonstrated by the following tests:

S12.2.5.1 Cycling—The assembled indicator and shutoff valves shall be cycled at a minimum of 25 000 cycles at the rate of 3 to 6 cycles per minute. The fluid level shall be varied between 20 to 80 % of the total indication level. Test temperature and pressure shall be in accordance with 803-5184222, Notes 17B, C, and D. During the cycling period, the following tests shall be conducted:

(a) After every 1000 cycles, the indicator shall be blown down by shutting the lower indicator shutoff valve and rapidly opening the indicator drain valve. Shut the drain valve and reopen the indicator lower shutoff valve.

(b) Thermal Shock. After every 3000 cycles, the indicator shall be allowed to cool to ambient temperature 24 ± 1°C (75 ± 2°F) and drained. The indicator shall be rapidly filled with hot water, 93 to 100°C (200 to 212°F) for glass tubes, 66°C (150°F) for rigid PVC tubes, to the maximum indication level. After 2 min, the indicator shall be drained and rapidly refilled with cold water, 10°C (50°F). Any evidence or spalling, cracking, breaking of the sight glass, or any abnormal wear or material deformation (during or at the end of the tests) shall constitute a failure.

S12.2.5.2 Hydrostatic—Upon completion of the 25 000 cycles, the indicator and valves shall be subjected to the hydrostatic test as specified in S8.2.

S12.2.6 Shock—Indicators shall be subjected to shock in accordance with MIL-S-901, Class I, Grade A for indirect indicators and Grade B for direct indicators. The indicators shall be tested as a complete assembly mounted on a Type 4-A mounting fixture. The shock test shall be performed in the following sequence:

(a) Valves open, indicator at 50 % fluid level and pressurized to normal working pressure. A total of nine blows shall be applied, three blows shall be applied parallel to each of the three principal axes.

(b) Valves shut, normal working pressure applied to valve inlet. Indicator dry and drain plug removed. A total of nine blows shall be applied, three blows shall be applied parallel to each of the three principal axes.

After exposure to shock, the indicator shall be refilled and the fluid level varied between 20 to 80 % to ensure satisfactory
operation. The shutoff valves shall be hydrostatically tested to 3.1 MPa (450 lb/in.\(^2\)) in the open position to check for body and valve stem leakage and the closed position to check for seat leakage. The indicators and valves shall be disassembled and visually examined for any damage.

S12.2.7 Vibration—The complete indicator assembly shall be subjected to vibration in accordance with MIL-STD-167-1, Type I. The indicator shall be filled to the 50% indication level and pressurized to normal working pressure during exposure to vibration. After exposure to vibration, the operation of the indicator shall be accurate when the fluid level is varied between 20 to 80% of the indicator range.

S13.1 Warranty—Special warranty requirements shall be specified in the acquisition requirements. Otherwise, the standard commercial warranty applies.

S14. Certification

S14.1 When specified in the purchase order or contract, the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data remain on file for three years at the manufacturer’s facility for review by buyer upon request.

S15. Product Marking

S15.1 Unique product marking or identification plate requirements shall be specified in the acquisition requirements.

S16. Packaging and Package Marking

S16.1 Packaging shall be in accordance with the requirements of Practice D 3951. Unique preservation, packaging, or package marking requirements shall be specified in the acquisition requirements.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

1. Scope

1.1 This specification covers various tachometers capable of measuring rotational shaft speed.

1.2 Special requirements for tachometer types used in naval shipboard applications are included in Supplement S1.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:
D 3951 Practice for Commercial Packaging

3. Terminology

3.1 Definitions:
3.1.1 SI (Le Systeme International d’Unites) Units—units of measurement recognized by the Comite' International des Poids et Mesures (CIPM).

3.1.2 tachometer—an instrument capable of generating, transmitting, and indicating information or signal that can be converted into a function of rotational speed.

4. Classification

4.1 Design Types—The following are among the types of tachometers available:
(a) Centrifugal;
(b) Centrifugal, flexible drive;
(c) Chonometric;
(d) Electrical, alternating current (ac) voltage responsive, direct drive;
(e) Electrical reactance;
(f) Electrical, magnetovoltmeter, direct drive;
(g) Electrical, magnetovoltmeter;
(h) Frequency responsive, electrical control box and voltmeter, direct drive;
(i) Frequency sensitive, electrical, nonrotating magnetic pickup, direct drive, consists of a magnetic pickup, transducer, and indicator;
(j) Photoelectric;
(k) Digital contact;
(l) Centrifugal, flexible drive; and
(m) Vibrating resonant reed.

5. Ordering Information

5.1 The buyer shall provide the manufacturer with all of the pertinent application data in accordance with the acquisition requirements, 5.2.

5.2 Acquisition Requirements—Acquisition documents shall specify the following:
(a) Title, number, and date of this specification;
(b) Quantity of tachometers required;
(c) Range;
(d) Manufacturer’s part number;
(e) When qualification inspection is required;
(f) Final disposition of qualification test samples;
(g) Type of electrical connection;
(h) Mounting method;
(i) Environmental requirements;
(j) Materials;
(k) Size and weight restrictions;
(l) Critical service life requirements;
(m) Performance requirements;
(n) Surface finish requirements;
(o) Cleaning requirements;
(p) When certification is required;
(q) Marking requirements;
(r) Packaging requirements; and
(s) Preservation requirements.

6. Materials and Manufacture

6.1 Material Selection—The materials for all parts shall be selected for long-term compatibility with the environment in which the tachometer will be installed or used.

6.2 Material Inspection—The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with the specifications and standards as applicable.
7. Physical Properties

7.1 Size and Weight—The buyer may have intended applications where size and weight are limited. Size and weight limitations shall be specified in the acquisition requirements.

8. Performance Requirements

8.1 Service Life—The buyer may have a minimum specified service life requirement. Critical service life requirements shall be specified in the acquisition requirements.

8.2 Tachometer Performance—Performance tolerances are usually specified in percentage of range span. The following performance characteristics and environmental exposures may or may not be important to each buyer’s intended application.

(a) Accuracy,
(b) Repeatability,
(c) Damping,
(d) Temperature,
(e) Humidity,
(f) Salt spray,
(g) Vibration,
(h) Shock, and
(i) Electromagnetic interference (EMI).

9. Workmanship, Finish, and Appearance

9.1 Cleaning, Finish, and Appearance— Any special cleaning, surface finish, and appearance requirements shall be specified in the acquisition requirements.

10. Inspection

10.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

(a) Qualification testing and
(b) Quality conformance testing.

10.2 Qualification Testing—Qualification test requirements shall be specified, where applicable. Test methods should be identified for each design and performance characteristic specified. Test report documentation requirements should also be specified.

10.3 Quality Conformance Testing—Quality conformance inspection is accomplished when acceptance and qualification testing is satisfied by a previous acquisition or when the product has demonstrated reliability in similar applications. Quality conformance inspection is usually less intensive than acceptance and qualification, often verifying that samples of a production lot meet a few critical performance requirements.

11. Number of Tests and Retests

11.1 Test Specimens—The number of test specimens to be subjected to qualification testing shall depend on the tachometer design. If each range is covered by a separate and distinct design, a test specimen for each range will require testing. In instances in which a singular design series may cover multiple ranges and types, it is recommended that three test specimens be tested provided the electrical and mechanical similarities are approved by the buyer. In no case, however, should less than three units, one unit each representing low, medium, and high ranges, be tested, regardless of design similarity.

12. Test Methods

12.1 Tests—All tests shall be performed in accordance with ASTM, ASME, or industry standards as specified.

12.2 Test Data—All test data shall remain on file at the manufacturer’s facility for review by the buyer upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years or a period of time acceptable to the buyer and manufacturer.

13.1 Warranty:

13.1.1 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:

(a) All materials used to produce a unit and
(b) Manufacturer will warrant his product to be free from defect of workmanship to produce the unit.

14. Certification

14.1 When specified in the purchase order or contract, the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification, and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

15. Product Marking

15.1 User-specified product marking shall be listed in the acquisition requirements. The minimum data to be clearly marked on each tachometer shall include the following:

(a) Manufacturer’s name,
(b) Manufacturer’s part number,
(c) Serial number or lot number,
(d) Date of manufacture, and
(e) Range.

16. Packaging and Package Marking

16.1 Packaging of Product for Delivery—Product shall be packaged for shipment in accordance with Practice D 3951.

16.2 Any special preservation, packaging, or package marking requirements for shipment or storage shall be identified in the acquisition requirements.

17. Keywords

17.1 tachometer
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard (Specification F 2046) and this supplement, the requirements of this supplement shall take precedence for equipment acquired by this supplement. This document supersedes MIL-T-16049C, Tachometers: Electrical; Self-Generating; Mechanical, Fixed Mounting, and Hand Held; and Vibrating Reed, for new ship construction. This document also supersedes MIL-T-24797, Tachometers, Fiber Optic, (Naval Shipboard Use), (Metric) General Specification for, for new ship construction.

TACHOMETERS: ELECTRIC AND FIBER OPTIC, FIXED MOUNTING

S1. Scope

S1.1 This supplement covers single-range noncontact electric and fiber-optic tachometers capable of generating, transmitting, and indicating information or signal that can be converted into a function of rotational speed. The subject tachometers may be used in shipboard systems, such as gas generators, power turbines, propulsion shafts, and gas steam turbine generators.

S1.2 Vibrating reed resonant-type tachometers are not covered in this specification.

S1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

S3. Terminology

S3.1 Definitions—Terms marked with (ANSI/ISA S37.1) are taken directly from ANSI/ISA S37.1 (R-1982) and are included for the convenience of the reader.
S3.1.1 ambient conditions—conditions, such as pressure and temperature, of the medium surrounding the case of a sensor (ANSI/ISA S37.1).
S3.1.2 calibration—test during which known values of measurands are applied to the sensor and corresponding output readings are recorded under specific conditions (ANSI/ISA S37.1).

3 Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.
5 Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111–5094, Attn: NPODS.
S3.1.3 environmental conditions—specified external conditions, such as shock, vibration, and temperature, to which a sensor may be exposed during shipping, storage, handling, and operation (ANSI/ISA S37.1).

S3.1.4 error—the error for a given value of the input variable (measurand) is the difference between the measured value of the output signal and the expected value of the output signal. The expected value of the output signal for any value of the measurand shall be represented by a straight line whose end points are given by:

S3.1.4.1 The specified value of the output signal at the minimum input value of the measurand (for example, 4 mA at the minimum specified rotational speed).

S3.1.4.2 The specified value of the output signal at the maximum input value of the measurand (for example, 20 mA at the maximum specified rotational speed).

S3.1.5 noncontact tachometer—any type of tachometer that senses or responds to rotational speed without physical contact or mechanical connection to the shaft being measured.

S3.1.6 operating environmental conditions—environmental conditions during exposure to which a sensor must perform in some specified manner (ANSI/ISA S37.1).

S3.1.7 optical—involving the use of light-sensitive devices to acquire information.

S3.1.8 optical fiber—a very thin filament or fiber, made of dielectric materials, that is enclosed by material of lower index of refraction and transmits light throughout its length by internal reflections.

S3.1.9 optoelectronics module—a component of the fiber optic tachometer that contains the optical source and detector, and signal conditioner devices necessary to convert the sensed rotational speed to a specified output signal.

S3.1.10 output—electrical or numerical quantity, produced by a sensor or measurement system, that is a function of the applied measurand.

S3.1.11 range—measurand values, over which a sensor is intended to measure, specified by their upper and lower limits (ANSI/ISA S37.1).

S3.1.12 repeatability—ability of a sensor to reproduce output readings when the same measurand value is applied to it consecutively, under the same conditions, and in the same direction (ANSI/ISA S37.1).

S3.1.13 sensor element—that part of the sensor that responds directly to the measurand (ANSI/ISA S37.1).

S3.1.14 sensor head—the transduction element of a fiber optic tachometer that detects rotational speed by means of changes in optical properties.

S3.1.15 sheath—the protective covering of a sensor element.

S3.1.16 signal conditioner—an electronic device that makes the output signal from a transduction element compatible with a readout system.

S3.1.17 span—the algebraic difference between the limits of the measurement range.

S3.1.18 static error band—the maximum deviation from a straight line drawn through the coordinates of the lower range limit at specified sensor output, and the upper range limit at specified output expressed in percentage of sensor span.

S3.1.19 supporting surface—surface on which the equipment is placed.

S3.1.20 target—description including items such as material, size, multiple reflectors, and surface features shall be as specified in the acquisition requirements.

S3.1.21 tachometer—an instrument capable of generating, transmitting, and indicating information or signal that can be converted into a function of rotational speed.

S3.1.22 warm-up time—the time required for a sensor to operate within specified accuracy, repeatability, and other critical parameters after being energized from a cold (ambient) state.

S4. Design Classification

S4.1 Electric Types:

S4.1.1 Designation—Tachometers shall be classified by a series of designations which shall be assigned and listed in the format following.

Example: F 2046-20M-BK-A

<table>
<thead>
<tr>
<th>Specification</th>
<th>Range (see S4.1.2)</th>
<th>Mounting (see S4.1.3)</th>
<th>Indicator (see S4.1.4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>F 2046</td>
<td>20M</td>
<td>BK</td>
<td>A</td>
</tr>
</tbody>
</table>

S4.1.2 Range—Electric tachometer ranges shall be selected from the standard ranges listed in Table S4.1.

S4.1.3 Mounting—Tachometer indicators shall be either bulkhead mounted (designator—BK) or panel (designator—PL) mounted.

S4.1.4 Indicator—Tachometer indicators shall be either analog (designator—A) or digital (designator—D).

S4.2 Fiber-Optic Type:

S4.2.1 Designation—The sensor classification shall consist of a series of designations which shall be assigned and listed in the form following.

Example: F 2046-DC-A-1
S4.2.2 Input Power—The input power required to operate the optoelectronics module shall be designated as follows:
dc—28-V direct current (Vdc)
ac—115-V alternating current (Vac)

S4.2.3 Optoelectronics Module—The mounting of the tachometer’s optoelectronics module type shall be designated as follows:
Type A—Bulkhead mounted (see S7.3.1)
Type B—Console mounted (see S7.3.2)

S4.2.4 Sensor Mounting Configuration—The tachometer’s sensor shall be mounted according to the following mount requirement type. The mass per unit length of the sensor mount configuration shall be no greater than 0.02 kg/mm. The dimensions of the tachometer’s sensor head shall be in accordance with Fig. S4.1.

S4.2.4.1 Mass—Unless otherwise specified, the mass of the optoelectronics module shall be not greater than 5 kg.

S4.2.4.2 Target—The target description including items such as material, size, multiple reflectors, and surface features shall be as specified in the acquisition requirements.

S4.2.5 Range—The fiber-optic tachometer range is an internal selection within the optoelectronics module with the following ranges:
0—1000 RPM
0—5000 RPM
0—10 000 RPM
0—20 000 RPM

S5. Ordering Information

S5.1 The buyer shall provide the manufacturer with all of the pertinent application data shown in S5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S5.2 Acquisition Requirements—Acquisition documents shall specify the following:
(a) Title, number, and date of this specification;
(b) Type and quantity required;
(c) Whether panel or bulkhead mounting is required;
(d) Range required;
(e) National Stock Numbers (NSNs) if available;
(f) When self-contained red illumination is required;
(g) Whether tachometer, control box, and indicator should be other than drip-proof construction;
(h) Number of additional indicators, if required;
(i) When qualification testing is required;
(j) Disposition of qualification test samples;
(k) Analog or digital indicator requirement;
(l) Special levels of preservation-packaging and packing required; and
(m) Product marking and labeling required.

S5.2.1 Fiber-Optic Requirements—In addition to the requirements outlined in S5.2, acquisition documents for fiber-optic tachometers should specify the following:
(a) Classification (see S4.2.1):
   (1) Input power,
   (2) Optoelectronics module,
   (3) Signal output, and
   (4) Range.
(b) Whether bulkhead or console mounting is required.
(c) Type and quantity of indicator(s) required.
(d) Whether junction box should be other than drip-proof construction.

S6. Materials and Manufacture

S6.1 Metals—Unless otherwise specified herein, all metals used in the construction of the tachometer shall be corrosion resistant. Dissimilar metals shall not be used in close physical contact with each other unless suitably finished to prevent electrolytic corrosion.

S6.2 Flammable Materials—Materials used in the construction of the tachometer shall, in the end configuration, be noncombustible or retardant in the most hazardous conditions of atmosphere, pressure, and temperature to be expected in the application.

S6.3 Fungus-Resistant Materials—Materials used in the construction of the tachometer shall be fungus-inert materials.

![Figure S4.1 Sensor Head Construction](image)
S6.4 Solvents, Adhesives, and Cleaning Agents—If any chemicals or cements are used in bonding of internal tachometer components, no degradation of these components shall result during in-service use.

S6.5 Refractive Index Matching Gels, Fluids, or Compounds—Refractive index matching gels, fluids, or compounds for fiber-optic tachometers shall be in accordance with MIL-M-24794.

S7. Physical Properties

S7.1 Electric Tachometers—Electric tachometers shall be a noncontact design and shall provide an output proportional to the continuous instantaneous shaft speed. Tachometers shall be for fixed mounted type of installations in which ranges from 100 to 100 000 RPM are permitted. Unless otherwise specified, the sensor, control box, and indicator shall be of drip-proof construction.

S7.1.1 Sensor—The sensor shall produce a signal by magnetic pulse, light pulse, or other noncontact method for input to the control box. The method of mounting or adapting the sensor may be varied to suit the machinery details.

S7.1.2 Control Box—The control box shall include the necessary electronics to process the sensor signal for driving the indicator. The sensor and control box may be combined in a single unit.

S7.1.3 Indicator—The indicator shall be capable of panel or bulkhead mounting. The indicator shall be analog or digital, as specified in the acquisition requirements. The analog indicator shall be a nominal 4 1/2- or 6-in. round scale with a 250° minimum arc. The digital indicator may be a round or rectangular liquid crystal or light-emitting diode display with readout numerals a minimum of 1 cm in height. A stop shall be provided in analog indicators to prevent the indicating pointer from going past full-scale reading. Analog indicators shall have self-contained red illumination.

S7.1.3.1 Dial and Pointer for Analog Indicators—The dial shall be of a corrosion-resistant material that will not warp at 90°C. The dial shall have a dull white finish with scale markings, numerals, and pointer a dull black. Dial and pointer assembly shall be of commercial design.

S7.1.3.2 Display or Indicator Windows—The display shall be protected by a window of high-quality plastic, free from flaws and defects, that does not cause parallax error.

S7.1.4 Dimensions and Weights (Maximum)—Dimensions and weights of the indicator shall be as shown in Table S7.1.

S7.1.5 Mounting—The indicator shall be designed for panel or bulkhead mounting.

S7.1.6 Operating Characteristics—The tachometers shall instantaneously and continuously indicate information or a signal that can be converted into a function of the speed of rotation in RPM of the rotating part being measured. The tachometers shall indicate, without change or adjustment, regardless of the direction of rotation of the driving part on the same scale.

S7.2 Fiber-Optic Tachometers—The fiber-optic tachometer shall be a noncontact device capable of converting a rotational speed to a continuous output signal throughout a specified measurement range. A fiber-optic tachometer shall consist of a sensor head, optoelectronics module, and fiber-optic cable connector at both ends. The optoelectronics module translates the optical input from the sensor head to a continuous linear proportional analog electrical signal or other output signal such as optical and digital.

S7.2.1 Sensor Head—The sensor head(s) shall be passive and detect shaft rotation through change in optical properties. The beam interruption sensing mechanism shall consist of two sensor heads. One sensor head shall be used to transmit, and one sensor head shall be used to receive an optical signal (generated from the optoelectronics module) across an air gap. Neither electrical nor electronic components shall be used in the construction of the sensor head. The configuration and physical dimensions of the sensor head(s) shall be as specified.

S7.2.2 Optoelectronics Module Mounting—The optoelectronics module mounting shall be either bulkhead or console mounted as specified.

S7.2.2.1 Bulkhead Mounted (Type A)—The optoelectronics module shall be housed in a junction box.

S7.2.2.2 Console Mounted (Type B)—The optoelectronics module shall be packaged in a circuit card that is a modular subassembly of a control console. Design and test requirements for the optoelectronics module shall be as specified.

S7.2.3 Fiber-Optic Cable—For integrity, the cable shall have an outer diameter of a four-fiber cable in accordance with MIL-C-85045. In the cable, there shall be no less than two times the number of fibers needed for operation of the sensor. The cable shall be supplied with a stuffing tube, packing assembly, and an O-ring, installed on each end of the cable to accomplish watertight penetration into the sensor head and optoelectronics module. Exposed single-fiber OFCC shall not be used over distances greater than 1 m. The length of cable shall be as specified.

S7.2.3.1 Optical Fiber—Optical fiber used to transmit light between the optoelectronics unit and the sensor head shall be in accordance with MIL-F-49291.

S7.2.3.2 Fiber-Optic Connectors, Receptacles, and Bulkhead Adapters—Fiber-optic connectors, receptacles, or bulkhead adapters used shall be in accordance with MIL-C-83522 and MIL-C-83522/16, 17, 18, respectively. Connectors shall be assembled at both ends of the fiber-optic cable between the sensor head and the optoelectronics module. The connectors and receptacles shall be mounted inside the sensor head or optoelectronics module.

S7.2.4 Electrical Input Power Requirements—Nominal steady-state power supply requirements for ac shall be 115 ± 8 V, 60 ± 2 Hz, single phase. Nominal steady-state power supply requirements for dc shall be 28 ± 4.5 V. The tachometer shall meet all performance requirements specified herein while operating with specified power supply voltages and their tolerances.
S7.2.5 Output Signal—The output signal of the tachometer shall be directly proportional to the speed being measured. A means shall be provided for internal selection (within the optoelectronics module) between the following output signals: true current source of 4 to 20 mA, 0 to 1 mA, 0 to 2 mA, 0 to 5 mA; true voltage source of 0–5 V or 0–10 V dc, and frequency (including TTL compatibility). A means shall also be provided for internal indication of the output signal selected. The complexity of this adjustment shall be such that one individual working alone is capable of performing this adjustment. The adjustment shall not require electrical disconnection.

S7.2.5.1 Current Output—The 0– or 4–mA output shall correspond to the lower speed range value and the 1–, 2–, 5–, or 20–mA output shall correspond to the upper speed range value. The current output shall remain accurate regardless of external load resistance variations over a range of 0 to 250 Ω.

S7.2.5.2 Voltage Output—The 0–Vdc output shall correspond to the lower speed range value, and the 5– or 10–Vdc output shall correspond to the upper speed range value. The voltage output shall remain accurate regardless of external load resistances greater than 100 000 Ω.

S7.2.5.3 Optical Output—When an optical output is required, all requirements shall be as specified.

S7.2.5.4 Digital Output—When an electrical digital output is required, all requirements shall be as specified. The electrical characteristics shall be in accordance with EIA Standard RS-422 for balanced voltage digital interface circuitry or as specified. The data format shall be as specified.

S7.2.6 Electrical Connectors—A single electrical connector and mating plug in accordance with MIL-C-5015 shall be used to interface the input power and linear output signal to the optoelectronics module. The appropriate connector assembly and pin designations for each of the possible tachometer configurations shall be as follows:

| S7.2.6.1 dc Input and Current or Voltage Output | The receptacle mounted to the optoelectronics module shall be Classification MS3452W14S-5PX in accordance with MS3452. Receptacle Pin “A” shall be +28–Vdc power input, Pin “B” shall be −28–Vdc power input, Pin “C” shall be case ground, Pin “D” shall be a +mA or Vdc signal output, and Pin “E” shall be a −mA or Vdc signal output. The mating plug shall be Classification MS3456W14S-5SX in accordance with MS3456. |
| S7.2.6.2 dc Input and Frequency Output | The receptacle mounted to the optoelectronics module shall be Classification MS3452W14S-5PX in accordance with MS3452. Receptacle Pin “A” shall be +28–Vdc power input, Pin “B” shall be −28–Vdc power input, Pin “C” shall be case ground, and Pins “D” and “E” shall be frequency signal outputs. The mating plug shall be Classification MS3456W14S-5SX in accordance with MS3456. |
| S7.2.6.3 ac Input and Current or Voltage Output | The receptacle mounted to the optoelectronics module shall be Classification MS3452W14S-5PX in accordance with MS3452. Receptacle Pins “A” and “B” shall be 115–Vac power input, Pin “C” shall be case ground, Pin “D” shall be a +mA or Vdc signal output, and Pin “E” shall be a −mA or Vdc signal output. The mating plug shall be Classification MS3456W14S-5SX in accordance with MS3456. |

S7.2.6.4 ac Input and Frequency Output—The receptacle mounted to the optoelectronics module shall be Classification MS3452W14S-5PX in accordance with MS3452. Receptacle Pins “A” and “B” shall be 115–Vac power input, Pin “C” shall be case ground, Pins “D” and “E” shall be frequency signal outputs. The mating plug shall be Classification MS3456W14S-5SX in accordance with MS3456.

S7.2.6.5 Digital Output—The connector assembly for a digital output signal shall be as specified.

S7.2.7 RPM Range Selection—A means shall be provided for internal selection (within the optoelectronics module) between the following rpm ranges: 0 to 1000, 0 to 5000, 0 to 10 000, and 0 to 20 000. A means shall also be provided for internal indication of the rpm range selected. The complexity of this adjustment shall be such that one individual working alone is capable of performing this adjustment. The adjustment shall not require electrical disconnection.

S7.2.8 Low-Intensity Alarm Indication—The optoelectronics module shall have a red LED which shall light when the intensity of the tachometer’s optical signal falls below a preset level. The LED shall be located on either the top or front of the module as it would be mounted during typical usage. The LED shall be visible in typical fluorescent room lighting. The optoelectronics alarm will allow for an indication that maintenance is required before a false output signal from the tachometer.

S7.2.8.1 Low-Intensity Alarm Set Point Adjustment—A means shall be provided for adjusting the low-intensity alarm set point over no less than one half of the dynamic range of the tachometer. A means of securing this adjustment shall be provided. The low-intensity alarm set point shall be capable of adjustment by one individual without the necessity for any electrical disconnection. Alarm set point adjustments shall be labeled and shall be accessible when the optoelectronics enclosure cover is removed.

S7.2.9 Sensitivity Adjustment—The tachometer shall have a sensitivity adjustment for increasing or decreasing the electrical pulse height of the optical signal over the dynamic range of the tachometer. The tachometer’s sensitivity shall be adjustable by one individual without the necessity for any electrical disconnection. Sensitivity adjustments shall be labeled and shall be accessible when the optoelectronics enclosure cover is removed.

S7.2.10 Fuses—The optoelectronics module shall not be fused.

S8. Performance Requirements

S8.1 Accuracy, Repeatability, and Damping—The accuracy of the tachometer shall be no less than 1 % of full-scale reading at any part of the scale at any ambient temperature between 5 and 65°C. The accuracy requirement shall be met during three calibration cycles to demonstrate repeatability. The accuracy requirements shall be met within 2 s of the sensor receiving an input signal and at any temperature between 5 and 65°C to demonstrate damping requirements.

S8.2 Reference Measurement—The referenced accuracy of each of the output signals of the fiber optic tachometer shall be
within ±1.0 % of the output span. Measurements shall be made at 10, 50, and 90 % intervals of span without any alignments or adjustments.

S8.3 Magnetizing—The materials used in the construction of the tachometers shall have such characteristics that no error, either temporary or permanent, in excess of the errors permitted under the accuracy requirements specified for the applicable type will be introduced when the tachometer is tested as specified in S12.2.3. Posttest reference measurements shall meet the requirements of S8.2.

S8.4 Accelerated Life—The tachometers shall be capable of demonstrating reliable operation within the accuracy requirements when subjected to the conditions within the performance parameters yet configured to induce accelerated life conditions (see S12.2.4).

S8.5 Sensitivity (Fiber Optic Only)—The ratio of the tachometer output in percent change of span to speed input in percentage change of span shall not be less than 0.75 or more than 1.25.

S8.6 Response Time (Fiber Optic Only)—The time for the tachometer output signal to indicate a steady-state speed (that is, 5000, 10,000, or 20,000 rpm) shall not be greater than 2 s after the test standard attains a steady-state speed.

S8.7 Warm-Up Time (Fiber Optic Only)—The tachometer shall attain an output value within ±1 % of the output span. Output shall reach this band in no more than 1 min after the tachometer is energized and shall remain in this band.

S8.8 Dynamic Range (Fiber Optic Only)—The dynamic range of the tachometer shall be no less than 35 dB for tachometers using the beam interruption sensing mechanism. The dynamic range of the tachometer shall be no less than 16 dB for tachometers using the reflection and magneto-optic sensing mechanism.

S8.9 Ambient Light Susceptibility (Fiber Optic Only)—This test is applicable for tachometers using the reflection and beam interruption sensing mechanism only. Monitored tachometer output during the ambient light susceptibility test shall show no deviation greater than ±1 % of the output span.

S8.10 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc) (Fiber Optic Only)—The tachometer shall exhibit no damage and shall be in accordance with the requirements of S8.2 during each of the specified test conditions.

S8.11 Transient Voltage and Frequency (ac) or Voltage (dc) (Fiber Optic Only)—The tachometer shall exhibit no damage and reference measurements shall be in accordance with the requirements of S8.2 following each of the transient conditions.

S8.12 Insulation Resistance (Fiber Optic Only)—The insulation resistance of the optoelectronics module shall not be less than 10 MΩ.

S8.13 Power Interruption (Fiber Optic Only)—The tachometer shall exhibit no damage and shall be in accordance with the requirements of S8.2 when power is reapplied following each of the power interruption intervals.

S8.14 Short Circuit (Fiber Optic Only)—The tachometer shall exhibit no damage and shall be in accordance with the requirements of S8.2 following the short-circuit test.

S8.15 Line Voltage Reversal (dc Input) (Fiber Optic Only)—The tachometer shall exhibit no damage and shall be in accordance with the requirements of S8.2 following the line voltage reversal test.

S8.16 Temperature (Fiber Optic Only)—During the temperature test, monitored tachometer output shall show no deviation greater than ±1 % of the output span. Following this test, the tachometer shall be in accordance with the requirements of S8.2.

S8.17 Humidity (Fiber Optic Only)—The tachometer shall be in accordance with the requirements of S8.2 without any alignments or adjustments. After testing is completed, there shall be no evidence of physical degradation, such as corrosion of metal parts or distortion of plastic parts.

S8.18 Enclosure (Fiber Optic Only)—There shall be no evidence of water penetration into the tachometer components either during or at the conclusion of the enclosure test. During the enclosure test, monitored tachometer output shall show no deviation greater than ±1 % of the output span. The tachometer shall be in accordance with the requirements of S8.2 following the enclosure test.

S8.19 Salt Spray (Fiber Optic Only)—Following this test, the tachometer shall show no appreciable corrosion or other damage, either optical, mechanical, or electrical that will affect its operation, and it shall be in accordance with the requirements of S8.2.

S8.20 Vibration—Tachometers shall conform to the vibration requirements of MIL-STD-167-1 (see S12.2.20). Monitored tachometer output during all phases of the vibration test shall show no deviation greater than ±1 % of the output span. Pretest and posttest reference measurements shall be in accordance with the requirements of S8.2. The tachometer shall show no evidence of physical damage that impairs its operation as a result of the vibration test.

S8.21 Shock—Tachometers shall conform to the shock requirements of Type A, Class I, Grade A for lightweight equipment of MIL-S-901. Monitored tachometer output during all phases of the shock test shall show no evidence of physical damage greater than ±1 % of the output span. Pretest and posttest reference measurements shall be in accordance with the requirements of S8.2. The tachometer shall show no evidence of physical damage that impairs its operation as a result of the shock test.

S8.22 Electromagnetic Interference (EMI) Emission and Susceptibility—Tachometers shall conform to the electromagnetic interference requirements of MIL-STD-461 (see S12.2.22). The tachometers shall be in accordance with MIL-STD-461 requirements CE101, CE102, CS101, CS114, CS116, RE101, RS101, RS103, and RS105. Monitored tachometer output during all phases of the EMI test shall show no deviation greater than ±1 % of the output span. Pretest and posttest reference measurements shall be in accordance with the requirements of S8.2.

S9. Workmanship, Finish, and Appearance

S9.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, and machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids, and gaps as well as sand, dirt, fins, sharp edges,
scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change as a result of heat from welding operation.

S10. Inspection

S10.1 Inspection System—The manufacturer shall provide and maintain an inspection system acceptable to the buyer for supplies and services covered by this specification. The testing set forth in this specification shall become a part of the manufacturer’s overall inspection system or quality program. The manufacturer’s quality system shall comply with the requirements of ANSI/ASQC 9001-1994. Certification and registration is highly desired but not required.

S10.2 Classification of Inspections—The inspection requirements specified herein are classified as follows:
(a) Qualification testing and
(b) Quality conformance testing.

S10.3 Qualification Testing—One sample tachometer shall be subjected to the examination and tests specified in Table S10.1. Failure of any tachometer to meet the requirements of this specification shall be cause for rejection.

S10.4 Quality Conformance Testing—Each tachometer shall be subjected to the tests specified in Table S10.2. The results of each examination and test shall be compared to the requirements of this specification. If any tachometer fails in the examination or in any test, it shall be rejected.

S10.5 Order of Inspection—The sample tachometers shall be subjected to the inspections specified in Tables S10.1 and S10.2 in the order listed except that the steady-state supply voltage and frequency inspection may be performed concurrently with the temperature inspection.

S10.6 General Examination—Each tachometer shall be given a thorough examination to determine conformance to the requirements of this specification with respect to material, finish, workmanship, construction, assembly, dimensions, weight, and marking of identification. Examination shall be limited to the examinations that may be performed without disassembling the units. Examination shall also include a check of all adjustments. The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with the specifications and standards as applicable.

S11. Number of Tests and Retests

S11.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S12. Test Methods

S12.1 Test Conditions—Unless otherwise specified herein, the fiber-optic tachometer(s) shall be fully assembled and energized throughout the duration of each test procedure. Except where the following factors are the variables, the tests specified in S10.2 shall be conducted with the equipment under the following operating environmental conditions:
(a) Ambient temperature shall be 25 ± 5°C,
(b) Relative humidity shall be ambient,
(c) Supply voltage shall be 115 V (nominal) for input power designation ac or 28 V (nominal) for input power designation dc,
(d) Supply frequency shall be 60 Hz (nominal) for input power designation ac or dc for input power designation dc,
(e) Distance from sensor head to target shall be 10 mm for fiber-optic tachometers using reflection and beam interruption sensing mechanisms, and
(f) Distance from sensor head to target shall be 2 mm for fiber-optic tachometers using magneto-optic sensing mechanism.

S12.2 Test Methods:

S12.2.1 Accuracy—The tachometer shall first be operated over its full speed range by slowly increasing and decreasing the applied speed in four continuous cycles. The calibration measurements shall be made at a minimum often equally spaced intervals over the full range. This calibration procedure shall be applied three successive times to determine repeatability. The fiber optic tachometer shall be energized and operational at a speed range setting of 0 to 20 000 rpm. A measurement of each of the outputs of the optoelectronics module shall be performed at the following speeds: 5000, 10 000, 15 000, and 20 000 rpm. This measurement shall be performed three successive times for each of the optoelectronics module outputs (see S8.2). The maximum difference
between any two output values at the same speed for each of the optoelectronics module output signal selections shall determine repeatability. Accuracy, repeatability, and damping shall meet the requirements of S8.1.

S12.2.1.1 Temperature—Accuracy tests shall be conducted at 5, 25, and 65°C. The accuracy shall be checked at a minimum of five equally spaced operating speeds over the range of the tachometer. The tachometer shall conform to the accuracy requirements of S8.1.

S12.2.2 Reference Measurement—The tachometer shall be energized and operational. A measurement shall be made at 10, 50, and 90 % intervals of span both upscale and downside. The accuracy at all points of measurement shall meet the requirements of S12.2.1.

S12.2.3 Magnetizing—While operating at a constant speed of approximately 50 % of full-scale range, the tachometer shall be placed in varying positions in a unidirectional, magnetic field having a flux density in free air of approximately 5 gausses. The error of tachometers shall be within the requirements specified in S8.2.

S12.2.4 Accelerated Life—Tachometers shall be operated at a constant speed approximately equal to the midpoint of their range for four periods. The periods shall be as follows:

<table>
<thead>
<tr>
<th>Period</th>
<th>Duration</th>
<th>Temperature</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>25 h</td>
<td>25°C</td>
</tr>
<tr>
<td>2</td>
<td>25 h</td>
<td>5°C</td>
</tr>
<tr>
<td>3</td>
<td>25 h</td>
<td>65°C</td>
</tr>
<tr>
<td>4</td>
<td>25 h</td>
<td>25°C</td>
</tr>
</tbody>
</table>

Relative humidity shall be varied during Periods 2 and 3 between approximately 50 and 90 % in alternate hour periods. All tachometers shall operate satisfactorily during these tests within their required accuracy as specified in S8.1.

S12.2.5 Sensitivity (Fiber Optic Only)—The sensitivity factor shall be determined using the following procedure:
(a) The tachometer shall be energized and operational at an output signal, of the 0- to 10-V setting corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm.
(b) Measure both the shaft speed and the optoelectronics module output signal.
(c) Increase the shaft speed by an amount not greater than 1 % of the output span.
(d) Measure both the new shaft speed and the optoelectronics module output signal.
(e) Calculate the change in both shaft speed and the optoelectronics module output signal as a percentage of the output span.
(f) Determine the ratio of the output percentage change to applied shaft speed percentage change in terms of the output span.
(g) Repeat this procedure for shaft speed decrease not greater than 1 % of the output span.

S12.2.6 Response Time (Fiber Optic Only)—The response time shall be determined by the following procedure:
(a) Energize the fiber optic tachometer and set the position of the sensor head.
(b) Adjust the tachometer’s output signal to the 0- to 10-V setting and the rpm setting to the 0- to 10 000-rpm range.
(c) Energize the test standard and increase the speed of its rotating target to 5000 rpm. The test standard shall reach 5000 rpm within 2 s.
(d) Monitor the output signal of the tachometer and the test standard during the test.

S12.2.7 Warm-Up Time—The warm-up time shall be determined by the following procedure:
(a) Allow the tachometer output signal to stabilize at a value, of the 0- to 5-V setting, corresponding to a measurand operating speed of 800 rpm. The tachometer’s speed range setting shall be 0 to 1000 rpm.
(b) Deenergize the tachometer for no less than 2 h.
(c) Reenergize the tachometer and monitor the optoelectronics module output as necessary to ensure tachometer meets the requirements of S8.7.

S12.2.8 Dynamic Range (Fiber Optic Only)—The dynamic range of the optoelectronics module shall be tested in accordance with the following procedures:

S12.2.8.1 Beam Interruption—A calibrated optical attenuator with two jumpers shall be tested for insertion loss in accordance with EIA-455-34. The attenuator shall then be connected between the optoelectronics module and the sensor head of the transmitting optical signal by means of the two jumper cables. The tachometer’s sensitivity shall be adjusted to the maximum setting. The attenuation shall be increased from 0 dB (encompassing insertion loss of attenuator and jumpers) to 35 dB. The tachometer shall be operating at an output signal value, of the 0- to 5-V setting, corresponding to an operating speed of 800 rpm. The tachometer’s speed range setting shall be 0 to 1000 rpm. The dynamic range will be exceeded when the output signal drops to a value equivalent to 0 rpm. Performance shall be in accordance with the requirements of S8.8.

S12.2.8.2 Reflection and Magneto-Optic Effect—A calibrated optical attenuator with two jumpers shall be tested for insertion loss in accordance with EIA-455-34. The attenuator shall be connected between the optoelectronics module and the sensor head via the two jumper cables. The tachometer’s sensitivity shall be adjusted to the maximum setting. The attenuation shall increase from 0 dB (encompassing insertion loss of attenuator and jumpers) to 16 dB. The tachometer shall be operating at an output signal value, of the 0- to 5-V setting, corresponding to an operating speed of 800 rpm. The tachometer’s speed range setting shall be 0 to 1000 rpm. The dynamic range will be exceeded when the output signal drops to a value equivalent to 0 rpm. Performance shall be in accordance with the requirements of S8.8.

S12.2.9 Ambient Light Susceptibility (Fiber Optic Only)—The ambient light source and general test conditions shall be in accordance with EIA-455-22. The tachometer shall be energized and placed in the beam of the light source for a 10-min duration. During the test, the tachometer shall be energized and operational at an output signal, of the 0- to 5-V setting, corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm. This output shall be monitored during the test. Performance shall be in accordance with the requirements of S8.9.

S12.2.10 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc) (Fiber Optic Only)—This test may be performed in conjunction with the temperature test (see
S12.2.16). For ac-powered tachometers, a reference measurement shall be performed at 0, 25, and 65°C for each of the conditions specified in S12.2.11.1 and S12.2.11.2. For dc-powered tachometers, a reference measurement shall be performed at 0, 25, and 65°C for each of the conditions specified in S12.2.11.3. The tachometer shall be allowed to stabilize at each testing temperature before the reference measurements are performed. Performance shall be in accordance with the requirements of S8.10.

S12.2.11 Transient Voltage and Frequency (ac) or Voltage (dc) (Fiber Optic Only)—Ac-powered tachometers shall be tested in accordance with S12.2.11.1 and S12.2.11.2. Dc-powered tachometers shall be tested in accordance with S12.2.11.3.

S12.2.11.1 Transient Voltage (ac):

S12.2.11.1.1 Upper Limit—With the tachometer operating at the steady-state voltage of 123 Vac, the voltage shall be increased to 138 Vac and then decreased back to the steady-state voltage of 123 Vac in a 2-s period. A reference measurement shall then be performed at 115 Vac. The tachometer shall be in accordance with the requirements of S8.2.

S12.2.11.1.2 Lower Limit—With the switch operating at a steady-state voltage of 107 Vac, the voltage shall be decreased to 92 Vac and then increased back to the steady-state voltage of 107 Vac in a 2-s period. A reference measurement shall then be performed at 115 Vac. The tachometer shall be in accordance with the requirements of S8.2.

S12.2.11.2 Transient Frequency (ac):

S12.2.11.2.1 Upper Limit—With the tachometer operating at a steady-state frequency of 62 Hz, the frequency shall be increased to 63.5 Hz and then decreased back to the steady-state frequency of 62 Hz in a 2-s period. A reference measurement shall then be performed at 60 Hz. The tachometer shall be in accordance with the requirements of S8.2.

S12.2.11.2.2 Lower Limit—With the tachometer operating at a steady-state frequency of 58 Hz, the frequency shall be decreased to 56.5 Hz and then increased back to the steady-state frequency of 58 Hz in a 2-s period. A reference measurement shall then be performed at 60 Hz. The tachometer shall meet the requirements of S8.2.

S12.2.11.3 Transient Voltage (dc):

S12.2.11.3.1 Upper Limit—With the tachometer operating at a steady-state voltage of 32.5 Vdc, the voltage shall be increased to 34.5 Vdc and then decreased back to the steady-state voltage of 32.5 Vdc in a 2-s period. A reference measurement shall then be performed at 28 Vdc. The tachometer shall be in accordance with the requirements of S8.2.

S12.2.11.3.2 Lower Limit—With the tachometer operating at a steady-state voltage of 23.5 Vdc, the voltage shall be decreased to 21.5 Vdc and then increased back to the steady-state voltage of 23.5 Vdc in a 2-s period. A reference measurement shall then be performed at 28 Vdc. The tachometer shall be in accordance with the requirements of S8.2.

S12.2.12 Insulation Resistance (Fiber Optic Only)—The insulation resistance of the optoelectronics module shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The temperature shall be 25 ± 5°C and the relative humidity shall be 50 ± 10%. The insulation resistance measurement shall be made immediately after a 2-min period of uninterrupted test voltage application. If the indication of insulation resistance meets the specified limit and is steady or increasing, the test may be terminated before the end of the 2-min period. The tachometer shall be in accordance with the requirements of S8.12.

S12.2.13 Power Interruption (Fiber Optic Only)—With the tachometer operating within the steady-state tolerances of voltage and frequency, the external power supply shall be suddenly interrupted. After an interval of between 3 and 4 s, the power supply, within the steady-state tolerances, shall be reapplied. After the tachometer has been operated long enough to detect any major performance degradation, the power shall be interrupted for an interval of no less than 30 s. This cycle, (3- to 4-s interruption, monitor, then an interruption of no less than 30 s) shall be repeated three times (four total cycles). Following each of the power interruption intervals, a reference measurement shall be made. The tachometer shall be in accordance with the requirements of S8.13.

S12.2.14 Short Circuit (Fiber Optic Only)—The tachometer shall be deenergized and the positive and negative electrical output leads or terminals of the optoelectronics module shall be connected directly together with no load resistance. The tachometer shall be energized for 5 min, then deenergized, and the short circuit removed. The tachometer shall be energized and a reference measurement shall be made at ambient temperature. The tachometer shall meet the requirements of S8.14.

S12.2.15 Line Voltage Reversal (for dc Powered Tachometers) (Fiber Optic Only)—A positive 28-Vdc signal shall be applied to connector Pin “B.” The dc reference signal shall be applied to connector Pin “A.” The power supply shall be energized for a period of 10 min and then shall be disconnected. The power supply shall then be correctly applied (Pin A positive, Pin B negative) and a reference measurement shall be made. The tachometer shall be in accordance with the requirements of S8.15.

S12.2.16 Temperature (Fiber Optic Only)—The tachometer shall be positioned in an environmental chamber in an energized state and shall be subjected to the following test procedure. Performance shall meet the requirements of S8.16.

(a) Hold test temperature at 0°C for no less than 24 h.
(b) Increase test temperature in steps of 10°C each, at 30 min for each step, until plus 65 ± 2°C is reached. Hold at that temperature for no less than 24 h.
(c) Reduce test temperature in steps of 10°C each, at 30 min for each step, until plus 25 ± 2°C is reached. Hold at that temperature for no less than 24 h.

During the last hour of operation at each temperature plateau (0, 65, and 25°C) the tachometer electrical output signal, of the 0- to 5-V setting, shall be measured corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm. After the temperature test, a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.16.

S12.2.17 Humidity (Fiber Optic Only)—The tachometer shall be subjected to the conditioning and tests specified in
S12.2.17.1 through S12.2.17.5. The tachometer shall be energized throughout the test. Performance shall be in accordance with the requirements of S8.17.

S12.2.17.1 Conditioning—To establish a reference condition for the measurement of operating parameters and a valid basis for comparison of the effects of the conditioning to follow, the complete equipment shall be dried at a temperature no less than 40°C or more than 500°C for no less than 2 h.

S12.2.17.2 Reference Measurements—Following the conditioning, a reference measurement shall be made at 25 ± 5°C and 50 ± 5% relative humidity. Performance shall be in accordance with the requirements of S8.17.

S12.2.17.3 Temperature Cycling—The tachometer shall then be subjected to four 24-h cycles of temperature variation consisting of 18 h at 65 ± 5°C and 6 h at 25 ± 5°C. The relative humidity shall be maintained at 90 to 95% (noncondensing) during the steady-state conditions. The transitions between temperatures shall be accomplished within the 6-h period so that the time at the high temperature is 18 h. Each transition shall be not greater than 1 h if the tachometer remains in the chamber or 15 min if a two-chamber method is used. The relative humidity need not be controlled during the transition periods.

S12.2.17.4 Measurement During Cycling—During the second cycle, a reference measurement shall be made at the end of the high temperature period with the tachometer remaining in the chamber at 65 ± 5°C. The tachometer shall be energized for as brief a period as required to complete the measurements.

S12.2.17.5 Measurements After Temperature Cycling—After the four complete cycles, a reference measurement shall be made at 25 ± 5°C with the tachometer remaining in the chamber. Performance shall meet the requirements of S8.17.

S12.2.18 Enclosure (Fiber Optic Only)—The tachometer shall be placed or mounted in a position typical of that for which it was designed. The surface upon which the equipment is placed or mounted (supporting surface) shall extend no less than 1 m beyond the equipment on all sides so that splashing may be produced by directing the water stream on the supporting surface. The water stream shall be a coarse spray with a flow rate of no less than 55 L/min and a head pressure of no less than 3 m. A head pressure of 3 m is defined as sufficient water pressure so that if directed straight up, the stream of water shall rise to a height of 3 m. The distance from the nozzle to the enclosure under test shall be approximately 2 m. The time of the test shall be no less than 5 min with approximately equal portions of time for spray on each surface, including joints of the enclosure and at the supporting surface. During the test, the tachometer shall be energized and operational at an output signal, of the 0- to 5-V setting, corresponding to a speed of 3000 rpm. This output signal shall be monitored during the test. After exposure to vibration, a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.20.

S12.2.19 Salt Spray (Fiber Optic Only)—Before exposure to salt spray, a reference measurement shall be made. The fiber-optic tachometer shall be deenergized and tested in accordance with Practice B 117. Duration of the test shall be 96 h. The tachometer’s major components shall be disassembled at the immediate conclusion of the test and examined for corrosion and moisture penetration. After exposure to salt spray, the tachometer shall be energized and a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.19.

S12.2.20 Vibration—Before exposure to vibration, a reference measurement shall be made. The tachometer shall be exposed to Type I vibration in accordance with MIL-STD-167-1. During vibration, the electric tachometer shall be energized and operational at a speed corresponding to the midpoint of full scale. During vibration, the fiber-optic tachometer shall be energized and operational at an output signal, of the 0- to 5-V setting, corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm. This output signal shall be monitored during the test. After exposure to vibration, a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.21.

S12.2.21 Shock—Before shock, a reference measurement shall be made. Electric tachometers shall be subjected to the Type A, Grade A, Class I, lightweight equipment test of MIL-S-901. During shock, electric tachometers shall be energized and operational at a speed corresponding to the midpoint of full scale. The fiber-optic tachometer equipment shall be exposed to shock in accordance with MIL-S-901, Grade A, Type C, Class I. The equipment shall be mounted on Fixture 4A simulating shipboard installation. During shock, the tachometer shall be energized and operational at an output signal, of the 0- to 5-V setting, corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm. This output signal shall be monitored during shock. After exposure to shock, a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.22.

S12.2.22 Electromagnetic Interference (EMI) Emission and Susceptibility—The tachometers shall be exposed to EMI in accordance with MIL-STD-461. During exposure to EMI, the electric tachometer shall be energized and operational at a speed corresponding to the midpoint of full scale. During exposure to EMI, the fiber-optic tachometer shall be energized and operational at an output signal, of the 0- to 5-V setting, corresponding to a speed of 3000 rpm. The tachometer’s speed range setting shall be 0 to 10 000 rpm. This output signal shall be monitored during exposure to EMI. After exposure to EMI, a reference measurement shall be made. Performance shall be in accordance with the requirements of S8.22.

S13.1 Warranty—Special warranty requirements shall be specified in the acquisition requirements. Otherwise, the standard commercial warranty applies.

S14. Certification

S14.1 When specified in the purchase order or contract, the buyer shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification, and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data
remain on file for three years at the manufacturer’s facility for review by buyer upon request.

**S15. Product Marking**

S15.1 Unique product marking requirements shall be specified in the acquisition requirements.

S15.2 **Fiber-Optic Tachometers:**

S15.2.1 **Optoelectronics Module**—Each optoelectronics module shall be permanently and legibly marked. The following minimum information shall be provided:

- (a) Nomenclature,
- (b) Design classification,
- (c) National Stock Number (NSN) if available,
- (d) Manufacturer’s name and model number,
- (e) Technical manual number,
- (f) Contract number, and
- (g) A unique serial number from the manufacturer.

S15.2.2 **Sensor Head**—Each sensor head shall be permanently and legibly marked in accordance with Practice D 3951. The following minimum information shall be provided:

- (a) Nomenclature,
- (b) Design classification,
- (c) National Stock Number (NSN) if available,
- (d) Manufacturer’s name and model number, and
- (e) A unique serial number from the manufacturer.

S15.2.3 **Labeling**—If laser radiation is used, a visible label shall be affixed to the outside of the optoelectronics module cover and shall contain the following:

**NOTICE**

**UNTERMINATED OPTICAL CONNECTIONS MAY EMIT LASER RADIATION. DO NOT VIEW BEAM WITH OPTICAL INSTRUMENTS AND AVOID DIRECT EXPOSURE TO THE BEAM.**

A visible label with yellow lettering on a black background shall be affixed to the sensor head and the inside of the optoelectronics module and shall contain the following:

**WARNING**

**INVISIBLE LASER RADIATION AVOID EXPOSURE TO THE BEAM**

S15.2.3.1 **Alternating Current**—Optoelectronics modules with input power designation ac shall be permanently and legibly marked with the following label:

**“WARNING 115VAC”**

**S16. Packaging and Package Marking**

S16.1 **Packing Requirements**—Tachometer equipment shall be preserved, packaged, and marked in accordance with Practice D 3951. Bar codes and other applicable packing acquisition options shall be specified.

---

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for Transducers, Pressure and Differential, Pressure, Electrical and Fiber-Optic

This standard is issued under the fixed designation F 2070; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the requirements for pressure and differential pressure transducers for general applications.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only. Where information is to be specified, it shall be stated in SI units.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices, and determine the applicability of regulatory limitations prior to use.

1.4 Special requirements for naval shipboard applications are included in Supplementary Requirements S1, S2, and S3.

2. Referenced Documents

2.1 ASTM Standards:
D 3951 Practice for Commercial Packaging

2.2 ANSI/ISA Standards:
ANSI/ISA S37.1 Electrical Transducer Nomenclature and Terminology

2.3 ISO Standard:
ISO 9001 Quality System—Model for Quality Assurance in Design/Development, Production, Installation, and Servicing

3. Terminology

3.1 Terms marked with (ANSI/ISA S37.1) are taken directly from ANSI/ISA S37.1 (R-1982) and are included for the convenience of the user.

Definitions—Terminology consistent with ANSI/ISA S37.1 shall apply, except as modified by the definitions listed as follows:

3.1.1 absolute pressure—pressure measured relative to zero pressure (vacuum) (ANSI/ISA S37.1)

3.1.2 ambient conditions—conditions such as pressure and temperature of the medium surrounding the case of the transducer (ANSI/ISA S37.1)

3.1.3 burst pressure—the maximum pressure applied to the transducer sensing element without rupture of the sensing element or transducer case as specified

3.1.4 calibration—the test during which known values of measurands are applied to the transducer and corresponding output readings are recorded under specified conditions (ANSI/ISA S37.1)

3.1.5 common mode pressure—the common mode pressure is static line pressure applied simultaneously to both pressure sides of the transducer for the differential pressure transducer only

3.1.6 differential pressure—the difference in pressure between two points of measurement (ANSI/ISA S37.1)

3.1.7 environmental conditions—specified external conditions, such as shock, vibration, and temperature, to which a transducer may be exposed during shipping, storage, handling, and operation (ANSI/ISA S37.1)

3.1.8 error—the algebraic difference between the indicated value and the true value of the measurand (ANSI/ISA S37.1)

3.1.9 fiber-optic pressure transducer—a device that converts fluid pressure, by means of changes in fiber-optic properties, to an output that is a function of the applied measurand. The fiber-optic pressure transducer normally consists of a sensor head, optoelectronics module, and connectorized fiber-optic cable

3.1.10 hysteresis—the maximum difference in output, at any measurand value within the specified range, when the value is approached first with increasing and then with decreasing measurand (ANSI/ISA S37.1)

3.1.11 insulation resistance—the resistance measured between insulated portions of a transducer and between the insulated portions of a transducer and ground when a specified dc voltage is applied under specified conditions

4 Available from International Organization for Standardization, Case Postale 56, Geneve, Switzerland CH-1211.
3.1.12 line pressure—the pressure relative to which a differential pressure transducer measures pressure. 

   (ANSI/ISA S37.1)

3.1.13 operating environmental conditions—environmental conditions during exposure to which a transducer must perform in some specified manner. 

   (ANSI/ISA S37.1)

3.1.14 optical—involving the use of light-sensitive devices to acquire information.

3.1.15 optical fiber—a very thin filament or fiber, made of dielectric materials, that is enclosed by material of lower index of refraction and transmits light throughout its length by internal reflections.

3.1.16 optoelectronics module—a component of the fiber-optic pressure transducer that contains the optical source and detector, and signal conditioner devices necessary to convert the sensed pressure to the specified output signal.

3.1.17 output—electrical or numerical quantity, produced by a transducer or measurement system, that is a function of the applied measurand.

3.1.18 overpressure—the maximum magnitude of a measurand that can be applied to a transducer without causing a change in performance beyond the specified tolerance.

3.1.19 pressure cycling—the specified minimum number of specified periodic pressure changes over which a transducer will operate and meet the specified performance.

3.1.20 pressure rating—the maximum allowable applied pressure of a differential pressure transducer.

3.1.21 process medium—the measured fluid (measurand) that comes in contact with the sensing element.

3.1.22 range—measurand values, over which a transducer is intended to measure, specified by their upper and lower limits. 

   (ANSI/ISA S37.1)

3.1.23 repeatability—ability of a transducer to reproduce output readings when the same measurand value is applied to it consecutively, under the same conditions, and in the same direction. 

   (ANSI/ISA S37.1)

3.1.24 response—the measured output of a transducer to a specified change in measurand.

3.1.25 ripple—the peak-to-peak ac component of the dc output.

3.1.26 sensing element—that part of the transducer that responds directly to the measurand. 

   (ANSI/ISA S37.1)

3.1.27 sensitivity factor—the ratio of the change in transducer output to a change in the value of the measurand.

3.1.28 sensor head—the transduction element of the fiber-optic pressure transducer that detects fluid pressure by means of changes in optical properties.

3.1.29 signal conditioner—an electronic device that makes the output signal from a transduction element compatible with a readout system.

3.1.30 static error band—static error band is the maximum deviation from a straight line drawn through the coordinates of the lower range limit at specified transducer output, and the upper range limit at specified transducer output expressed in percent of transducer span.

3.1.31 transducer—device that provides a usable output in response to a specified measurand. 

   (ANSI/ISA S37.1)

3.1.32 wetted parts—transducer components with at least one surface in direct contact with the process medium.

4. Classification

4.1 Designation—Most transducer manufacturers use designations or systematic numbering or identifying codes. Once understood, these designations could aid the purchaser in quickly identifying the transducer type, range, application, and other parameters.

4.2 Design—Pressure transducers typically consist of a sensing element that is in contact with the process medium and a transduction element that modifies the signal from the sensing element to produce an electrical or optical output. Some parts of the transducer may be hermetically sealed if those parts are sensitive to and may be exposed to moisture. Pressure connections must be threaded with appropriate fittings to connect the transducer to standard pipe fittings or to other appropriate leak-proof fittings. The output cable must be securely fastened to the body of the transducer. A variety of sensing elements are used in pressure transducers. The most common elements are diaphragms, bellows, capsules, Bourdon tubes, and piezoelectric crystals. The function of the sensing element is to produce a measurable response to applied pressure or vacuum. The response may be sensed directly on the element or a separate sensor may be used to detect element response. The following is a brief introduction to the major pressure sensing technology design categories.

4.2.1 Electrical Pressure Transducers:

4.2.1.1 Differential Transformer Transducer—Linear variable differential transformers (LVDT) are variable reluctance devices. Pressure-induced sensor movement, usually transmitted through a mechanical linkage, moves a core within a differential transformer. Sensors are most commonly bellows, capsules, or Bourdon tubes. The movement of the core within the differential transformer results in a change in reluctance that translates to a voltage output. An amplifying mechanical linkage may be used to obtain adequate core movement.

4.2.1.2 Potentiometric Transducer—Pressure-induced movement of the sensing element causes movement of a potentiometer wiper resulting in a change in resistance which translates to a voltage output. A bellows or Bourdon tube is commonly used as the sensing element. An amplifying mechanical linkage may be used to obtain accurate wiper movement.

4.2.1.3 Strain Gage Transducer—Typical strain gage pressure transducers convert a pressure into a change in resistance due to strain which translates to a relative voltage output. Pressure-induced movement in the sensing element deforms strain elements. The strain elements of a typical strain gage pressure transducer are active arms of a Wheatstone Bridge arrangement. As pressure increases, the bridge becomes electrically unbalanced as a result of the deformation of the strain elements providing a change in voltage output.

4.2.1.4 Variable Capacitance Transducer—Variable capacitance pressure transducers sense changes in capacitance with changes in pressure. Typically, a diaphragm is positioned between two stator plates. Pressure-induced diaphragm deflection changes the circuit capacitance, which is detected and translated into a change in voltage output.
4.2.1.5 Variable Reluctance Transducer—Variable reluctance pressure transducers sense changes in reluctance with changes in pressure. Typically, a diaphragm is positioned between two ferric core coil sensors that when excited produce a magnetic field. Pressure-induced diaphragm deflection changes the reluctance, which is detected and translated to a change in voltage output.

4.2.1.6 Piezoelectric Transducer—Piezoelectric transducers consist of crystals made of quartz, tourmaline, or ceramic material. Pressure-induced changes in crystal electrical properties cause the crystal to produce an electrical output which is detected and translated to a change in voltage output.

4.2.2 Fiber-Optic Pressure Transducers:

4.2.2.1 Fabry-Perot Interferometer—Fabry-Perot interferometers (FPI) consist of two mirrors facing each other, the space between the mirrors being called the cavity length. Light reflected in the FPI is wavelength modulated in exact accordance with the cavity length. Pressure-induced movement of one of the mirrors causes a measurable change in cavity length and a phase change in the reflected light signal. This change is optically detected and processed.

4.2.2.2 Bragg Grating Interferometer—A Bragg grating is contained in a section about 1 cm long and acts as a narrow band filter that detects variation in the optical properties of the fiber. When the fiber is illuminated with an ordinary light source such as an LED, only a narrow band of light will be reflected back from the grating section of the fiber. If a pressure is applied to the grating section of the fiber, the grating period changes, and hence, the wavelength of the reflected light, which can be measured.

4.2.2.3 Quartz Resonators—Typically, a pair of quartz resonators are inside the pressure transducer. These are excited by the incoming optical signal. One resonator is load-sensitive and vibrates at a frequency determined by the applied pressure. The second resonator vibrates at a frequency that varies with the internal temperature of the transducer. Optical frequency signals from the resonators are transmitted back to the optoelectronics interface unit. The interface unit provides an output of temperature-compensated pressure.

4.2.2.4 Micromachined Membrane/Diaphragm Deflection—The sensing element is made on a silicon substrate using photolithographic micromachining. The deflection of this micromachined membrane is detected and measured using light. The light is delivered to the sensor head through an optical fiber. The light returning from the membrane is proportional to the pressure deflection of the membrane and is delivered back to a detector through an optical fiber. The fiber and the sensor head are packaged within a thin tubing.

4.3 Types—The following are common types of pressure and differential pressure transducers: pressure, differential; pressure (gage, absolute and sealed); pressure, vacuum; and pressure, compound.

4.4 Process Medium—The following are the most common types of process media: freshwater, oil, condensate, steam, nitrogen and other inert gases, seawater, flue gas and ammonia, and oxygen.

4.5 Application—The following is provided as a general comparison of different types of transducers and considerations for application.

4.5.1 LVDT Transducer—The sensor element may become complicated depending on the amount of motion required for core displacement. Careful consideration should be exercised when the application includes very low- or high-pressure measurement, overpressure exposure, or high levels of vibration. Careful consideration should also be exercised when measuring differential pressure of process media having high dielectric constants, especially liquid media. If the process media is allowed to enter the gap between the sensor element and core, accuracy may suffer. Frequency response may suffer depending on the type of mechanical linkage(s) used in the transducer.

4.5.2 Potentiometric Pressure Transducer—Potentiometric pressure transducers are generally less complicated than other designs. Careful consideration should be exercised when the application includes very low pressure measurement, overpressure exposure, high levels of vibration, stability and repeatability over extended periods of time, or extremely high resolution requirements. Frequency response may suffer depending on the type of mechanical linkage(s) used. Technological advances have yielded more reliable designs that are commonly used.

4.5.3 Strain Gage Transducers—Low-level output strain gage transducers are among the most common pressure transducers. They are available in very compact packages which lend well in applications in which size is critical. Strain gage transducers that demonstrate high degrees of accuracy and excellent frequency response characteristics are readily available. Careful consideration should be exercised when the application includes very low-pressure measurement, very low lag or delay, high vibration levels, extreme overpressure requirements, or critical stability over extended periods.

4.5.4 Variable Capacitance Transducers—Variable capacitance transducers are well suited to measure dry, clean gases at very low pressures with a high degree of accuracy. Careful consideration should be exercised when measuring differential pressure of process media having high dielectric constants, especially liquid media. If the process media is allowed to enter the gap between the diaphragm and stators, accuracy may suffer. Process media that alters the dielectric constant between the diaphragm and stators also alters the output of the transducer unless isolation devices such as membranes or oil fills are used.

4.5.5 Variable Reluctance Transducers—Variable reluctance transducers are well suited to measure most process media, especially if the core coil sensors are isolated from the process media. Variable reluctance transducers are well suited for applications that include high shock or vibration levels, extreme overpressure requirements, high degrees of accuracy, or critical stability over extended periods. Careful consideration should be exercised when evaluating size, weight, and cost. All reluctance devices are affected by strong magnetic fields.

4.5.6 Piezoelectric Transducers—Piezoelectric transducers are very effective in measuring changes in pressure. The piezoelectric crystals only produce an output when they
experience a change in load. With adequate signal conditioners they can also be used to perform static measurements.

5.2.7 *Fiber-Optic Pressure Transducers*—Fiber-optic pressure transducers can be used in virtually all applications. They are extremely sensitive and are beneficial for high resolution measurements. They are unaffected by electromagnetic interference and are recommended in applications where EMI is a problem. These transducers are by nature intrinsically safe and are especially applicable for hazardous environments.

4.6 *Range*—Each manufacturer of transducers advertises a standard operating range for their offered selections but there is no industry-wide standard of specific ranges for transducers. Ranges are available that cover applications from vacuums to 210 MPaG (30 000 psig). Refer to individual manufacturer recommendations on range best suited to each application or specify an exact range if the range is a critical characteristic.

4.7 *Pressure Rating*—Pressure rating applies only to differential pressure transducers. Differential pressure transducers must be selected with a pressure rating for the maximum media pressure to be encountered. The purchaser should refer to specific manufacturer guidance to ensure a transducer has the proper pressure rating for each intended application.

4.8 *Power Supply*—Power supplies furnish excitation to the transducer. Power supplies may include batteries; line-powered, electronically regulated, dc power supplies; or ac power directly from the power system.

4.9 *Output*—Output signals can be electrical or optical dependent on design. Output must be measurable and must correspond with pressure applied within the range of the transducer. Multiple output signals shall be provided when specified. One signal shall be designated as the prime and the other as supplemental.

4.10 *Pressure Connection*—The pressure connection is the opening of the transducer used to allow the process medium to reach the sensing element. Differential pressure transducers have two pressure connections, a high-pressure port and a low-pressure port.

5. **Ordering Information**

5.1 The purchaser should provide the manufacturer with all of the pertinent application data shown in accordance with 5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they should also be described.

5.2 *Acquisition Requirements*—Acquisition documents should specify the following:

- 5.2.1 Title, number, and date of this specification,
- 5.2.2 Manufacturer’s part number,
- 5.2.3 Range, pressure rating (differential only), power supply, output,
- 5.2.4 Mounting method (see 7.2),
- 5.2.5 Type of pressure connection (see 7.5),
- 5.2.6 Type of electrical connection (see 7.4),
- 5.2.7 When an electrical connection mating plug is not to be provided (see 7.4),
- 5.2.8 System process medium,
- 5.2.9 Prime output signal,
- 5.2.10 Supplemental output signal, if required,
- 5.2.11 System operating characteristics, such as pressure and flow rate,
- 5.2.12 Materials,
- 5.2.13 Environmental requirements, such as vibration and ambient temperature,
- 5.2.14 Quantity of transducers required,
- 5.2.15 Size and weight restrictions (see 7.7),
- 5.2.16 Critical service life requirements (see 8.1),
- 5.2.17 Performance requirements (see 8.2),
- 5.2.18 Special surface finish requirements (see 9.1),
- 5.2.19 Special cleaning requirements (see 9.2),
- 5.2.20 When certification is required (see Section 13),
- 5.2.21 Special marking requirements (see Section 14),
- 5.2.22 Special packaging or package marking requirements (see Section 15),
- 5.2.23 When ISO 9001 quality assurance system is not required (see 16.1), and
- 5.2.24 Special warranty requirements (see 16.2).

6. **Materials and Manufacture**

6.1 *Sensing Elements*—The materials for the sensing element and wetted parts shall be selected for long-term compatibility (see 8.1) with the process medium (see 4.4).

7. **Physical Properties**

7.1 *Enclosure*—If case sealing is required, the mechanism, materials, and process shall be described. The same should apply to the electrical connector. The long-term resistance to common process media should be stated. Resistance to cleaning solvents should likewise be stated. Unique or special enclosure requirements shall be specified in the acquisition requirements (see 5.2).

7.2 *Transducer Mounting*—Transducers are commonly mounted directly by their pressure connections or through the use of brackets or similar hardware. Mounting force or torque shall be specified if it tends to affect transducer performance. Mounting error shall be specified in terms of percent of full-scale output or within the static error band under specified conditions of mounting force or torque.

7.3 *External Configuration*—The outline drawing shall show the configuration with dimensions in SI units (inch-pound units). The outline drawing shall include limiting dimensions for pressure and electrical connections if they are not specified. The outline drawing shall indicate the mounting method with hole size, center location, and other pertinent dimensions. Where threaded holes are used, thread specifications shall be provided.

7.4 *Standard Electrical Connection*—An electrical interface connector receptacle and mating plug shall be provided with each transducer unless otherwise specified in the contract (see 5.1). Optional possible electrical interface connections include pigtails and terminal boards.

7.5 *Pressure Connections*—Pressure connections commonly consist of pipe thread, hose tube fittings, O-ring union, O-ring union face seal, and others.

7.6 *Damping*—The use of a media for damping in transducers shall be specified including the type, composition, and compatibility with transducer components and materials.
7.7 Size and Weight—The purchaser may have intended applications in which size and weight are limited. Size and weight restrictions shall be specified in the ordering information (see 5.2).

8. Performance Requirements

8.1 Service Life—The purchaser may have a minimum specified service life requirement that may be critical. Critical service life requirements shall be specified in the ordering information (see 5.2).

8.2 Transducer Performance—Performance tolerances are usually specified in percent of transducer output span. Critical performance requirements shall be specified in the ordering information (see 5.2). The following performance characteristics and environmental exposures may or may not be important to each purchaser’s intended application: static error band, repeatability, hysteresis, sensitivity factor, ripple, warm-up time, steady-state supply voltage and frequency (ac), steady-state supply voltage (dc), response, transient supply voltage and frequency (ac), transient supply voltage (dc), temperature, humidity, overpressure, line pressure (differential only), salt spray, pressure cycling, insulation resistance, vibration, shock, burst pressure, output, enclosure, electromagnetic interference (EMI), common mode pressure (differential only), pressure rating (differential only), and power system harmonic distortion.

9. Workmanship, Finish and Appearance

9.1 Finish and Appearance—Any special surface finish and appearance requirements shall be specified in the ordering information (see 5.2).

9.2 Transducer Cleaning—Any special cleaning requirements shall be specified in the ordering information (see 5.2).

10. Number of Tests and Retests

10.1 Test Specimen—The number of test specimens to be subjected to first-article tests shall be specified and should depend on the transducer design. As guidance, if each range is covered by a separate and distinct design, a test specimen for each range should require testing. In instances in which a singular design series may cover multiple ranges and types, a minimum of three test specimens should be tested provided the singular design series may cover multiple ranges and types, a minimum of three test specimens should be tested provided the designer has identified that three units, one unit each representing the low, medium, and high ranges, be tested, regardless of design similarity.

10.1.1 Low Range—Less than 700 kPa (less than 100 lb/in.²).

10.1.2 Medium Range—700 kPa to less than 7 MPa (100 to less than 1000 lb/in.²).

10.1.3 High Range—7 MPa and greater (1000 lb/in.² and greater).

11. Test Methods

11.1 Test Data—All test data shall remain on file at the manufacturer’s facility for review by the purchaser upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years, or a period of time acceptable to the purchaser and the manufacturer.

12. Inspection

12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

12.1.1 First-article tests (see 12.2).

12.1.2 Conformance tests (see 12.3).

12.2 First-Article Tests—First-article test requirements shall be specified, where applicable. First-article test methods should be identified for each design and performance characteristic specified. Test report documentation requirements should also be specified.

12.3 Conformance Tests—Conformance testing shall be specified when applicable. Conformance testing shall be conducted on all units manufactured for delivery unless otherwise specified in the contract.

13. Certification

13.1 When specified in the acquisition requirements (see 5.2), the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met.

14. Product Marking

14.1 The purchaser specified product marking shall be listed in the acquisition requirements (see 5.2). The minimum data to be clearly marked on each transducer shall include the following:

14.1.1 Manufacturer's name,

14.1.2 Manufacturer’s part number,

14.1.3 Serial number or lot number,

14.1.4 Date of manufacture,

14.1.5 Range,

14.1.6 Excitation voltage, and

14.1.7 Pressure rating (differential pressure transducers only).

14.2 For differential pressure transducers, the high- and low-pressure connections shall be clearly marked on the transducer body adjacent to the connections.

15. Packaging and Package Marking

15.1 Packaging of Product for Delivery—The product should be packaged for shipment in accordance with Practice D 3951.

15.2 Any special packaging or package marking requirements for shipment or storage shall be identified in the ordering information (see 5.2).

16. Quality Assurance

16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see 5.2).

16.2 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:

16.2.1 All materials used to produce a unit and

16.2.2 Workmanship to produce the unit.

16.3 Special warranty requirements shall be specified in the acquisition requirements (see 5.2).
17. Keywords

17.1 differential pressure transmitter; fiber-optic pressure transducer; miniature; optoelectronics module; pressure and differential pressure transducers; pressure transmitter; sensing element; sensor head; transduction element

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirement, established for U.S. naval shipboard application, shall apply when specified in the contract or purchase order. When there is conflict between this specification and this supplementary requirement, this supplementary requirement shall take precedence. This document supersedes MIL-T-24742, Transducer, Pressure and Differential Pressure, Miniature (Electrical), for new ship construction.

S1. TRANSDUCERS, PRESSURE AND DIFFERENTIAL PRESSURE, MINIATURE (ELECTRICAL)

S1.1 Scope

S1.1.1 This supplement covers the requirements for miniature pressure and differential pressure transducers designed to meet the requirements for use on board naval ships.

S1.1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are provided for information only. Where information is to be specified, it shall be stated in SI units.

S1.2 Referenced Documents

S1.2.1 ISO Standard:

6149-1 Connections for Fluid Power and General Use—Ports and Stud Ends with ISO 261 Threads and O-Ring Sealing—Part 1: Ports with O-Ring Seal in Truncated Housing

S1.2.2 NEMA Standard:

250 Enclosures for Electrical Equipment (1000 Volts Maximum)

S1.2.3 Military Standards:

MIL-S-901 Shock Tests, H.I. (High-Impact); Shipboard Machinery, Equipment and Systems, Requirements for

MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment (Type I—Environmental and Type II—Internally Excited)

MIL-STD-461 Electromagnetic Interference Characteristics of Subsystems and Equipment, Requirements for the Control of

MIL-STD-1399, Section 300 Interface Standard for Shipboard Systems, Electric Power, Alternating Current

MS3452 Connector, Receptacle, Electric, Box Mounting, Rear Release, Crimp Contact, AN Type

MS3456 Connector, Plug, Electrical, Rear Release, Crimp Contact, AN type

S1.3 Terminology

S1.3.1 Terminology is consistent with that of Section 3 and the referenced documents.

5 Available from National Electrical Manufacturers Association, 1300 N. 17th St., Suite 1847, Rosslyn, VA 22209.
4—0-12 V
5—0-3 mV
6—0-200 µV

S1.4.7 Pressure Connection—Transducer pressure sensing connection shall be as follows:
N—M12 x 1.5 (7/16-20 UNF-2B) (see S1.7.5)
X—¼ nps, 155-mm (6-in.) long pipe nipple (see S1.7.5)
Z—Other

S1.4.8 Transducer Mounting—The transducer mounting method shall be designated as follows:
P—Pressure port connection
M—Mounting plate

S1.4.9 Range—The pressure range of the transducer shall be designated by two parts. The first part shall be the designator for the upper range value. The second part shall be the designator for the upper range unit of measure (see S1.4.9.1). The transducer pressure ranges shall be in accordance with Table S1.1.

S1.4.9.1 Units—The units shall be designated by the corresponding letter designator and are limited to the following:

S1.5 Ordering Information

S1.5.1 The purchaser shall provide the manufacturer with all of the pertinent application data in accordance with S1.5.2. If special application operating conditions exist that are not in the acquisition requirements, they shall also be described.

S1.5.2 Acquisition Requirements—Acquisition documents shall specify the following:
S1.5.2.1 Title, number, and date of this specification.
S1.5.2.2 Part designation.
S1.5.2.3 National Stock Number (NSN), if available.

<sup>A</sup>For upper range values of 7000 kPa (1000 lb/in.²) and above.
S1.5.2.4 Mounting method, if other than specified herein.
S1.5.2.5 Type of pressure connection, if other than specified herein.
S1.5.2.6 Type of electrical connection, if other than specified herein.
S1.5.2.7 When the electrical connection mating plug is not to be provided.
S1.5.2.8 Quantity of transducers required.
S1.5.2.9 If deviation requests are required when departing from material guidance.
S1.5.2.10 When first-article tests are required.
S1.5.2.11 Special product marking requirements.
S1.5.2.12 Special packaging or package marking requirements.
S1.5.2.13 When ISO 9001 quality assurance system is not required.
S1.5.2.14 Special warranty requirements.
S1.5.3 First-Article Tests—When first-article testing is required, the purchaser should provide specific guidance to offerors whether the item(s) should be a preproduction sample, a first-article sample, a first production item, a sample selected from the first production items, or a standard production item from the manufacturer’s current inventory. The number of items to be tested in accordance with S1.12.4 should be specified. The purchaser should include specific instructions in acquisition documents regarding arrangements for tests, approval of first-article test results and time period for approval, and disposition of first articles. Invitations for bids should provide that the purchaser reserves the right to waive the requirement for samples for first-article testing to those manufacturers offering a product that has been previously acquired or tested by the purchaser; and that manufacturers offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior purchaser approval is presently appropriate for the pending contract. The manufacture of items before purchaser approval should be specified as the responsibility of the manufacturer.

S1.6 Materials
S1.6.1 Sensing Elements—The materials for the sensing element and wetted parts shall be selected for long-term compatibility (see S1.8.1) with the process medium (see S1.4.3). Table S1.2 is provided for guidance as acceptable material and process medium compatibility. Dissimilar metals shall not be used in contact with each other unless suitably finished to prevent electrolytic corrosion. When departing from this guidance, the manufacturer shall provide evidence of material compatibility to the procuring activity, unless specified otherwise (see S1.5.1).

S1.7 Physical Properties
S1.7.1 Enclosure—The transducer body and pressure cavity shall be environmentally sealed unless otherwise specified. The transducer enclosure shall be Type 4 in accordance with NEMA Standard 250.
S1.7.2 Transducer Mounting—The transducer shall have a mounting plate as shown on Fig. S1.1. If required in a specific application and with prior approval of the purchaser, the transducer may be mounted by its pressure piping connection. For Type D transducers, the high-pressure port shall be used. If the transducer is mounted by its pressure connection, the mounting plate shall not be required (see S1.5.2). If the transducer is mounted by its pressure port connection and the mounting plate is provided, mounting holes shall not be required.

S1.7.3 External Configuration—The transducer shall have an external configuration within the boundaries established by Fig. S1.1.
S1.7.4 Electrical Connector—An electrical interface connector receptacle and mating plug shall be provided with each transducer unless otherwise specified. The electrical connector shall be a standard threaded coupling receptacle, AN type, MS3452W/14S-5P, or equivalent, for dc-power input, or AN type, MS3452W/14S-5PX, or equivalent, for ac-power input. The mating plug shall be a MS3456W/14S-5S, or equivalent, for dc-power input, or MS3456W/14S-5SX, or equivalent, for ac-power input.
S1.7.4.1 dc-Power Input—Output 2—The receptacle shall be wired to provide the performance described herein. Receptacle Pin A shall be +28-Vdc power input, Pin B shall be –28-Vdc power input, and Pin C shall be case ground. Receptacle Pins A and B shall also serve as the 4- to 20-mA dc signal output.
S1.7.4.2 dc-Power Input—Output 3, 4, 5, 6—The receptacle shall be wired to provide the performance described herein. Receptacle Pin A shall be +28-Vdc power input, Pin B shall be –28-Vdc power input, Pin C shall be case ground, Pin D shall be positive dc voltage signal output, and Pin E shall be negative dc voltage signal output.
S1.7.4.3 ac Power Input—Output 2—The receptacle shall be wired to provide the performance described herein. Receptacle Pins A and B shall be 115-Vac power input, Pin C shall be case ground, Pin D shall be +4- to 20-mA dc-signal output, and Pin E shall be –4- to 20-mA dc signal output.
S1.7.4.4 ac Power Input—Output 3, 4, 5, 6—The receptacle shall be wired to provide the performance described herein. Receptacle Pins A and B shall be 115-Vac power input, Pin C shall be case ground, Pin D shall be positive dc-voltage signal output, and Pin E shall be negative dc voltage signal output.
S1.7.5 Pressure Connections—Unless otherwise specified, transducer pressure-sensing connections for all services shall
be M12 × 1.5 (3/4-20 UNF-2B) tube connection in accordance with ISO 6149-1. When pressure connection Type X is specified, as commonly used on submarine oxygen replenishment systems, the transducer sensing connections shall be a nickel-copper pipe nipple 1/4 nominal pipe size (nps) with 3.1-mm (0.12-in.) minimum wall thickness, 155 mm (6 in.) long, welded to the socket (see S1.5.2). For Type D transducers, the high-pressure connection shall be on the end and the low-pressure connection shall be on the side (see Fig. S1.1).

S1.7.6 Welding—For Application X, all pressure boundary joints shall be welded.

S1.7.7 Lubrication—The transducer shall operate without lubrication of moving parts after assembly.

S1.7.8 Damping—The use of a media for damping in transducers shall be cited on the equipment drawing.

S1.7.9 Weight—The weight of a transducer shall not exceed 510 g (18 oz).

S1.8 Performance Requirements

S1.8.1 Service Life—The transducer shall be constructed for a life of 40 000 h of operation and shall meet the requirements specified herein when operated in the naval shipboard environment.

S1.8.2 Input Power—The transducer shall be designed to operate using 115-V, 60-Hz, single-phase, ungrounded, ac power as defined in MIL-STD-1399, Section 300 or 28 ± 4.5-Vdc power. The transducer shall operate with power supply variations as specified in S1.11.2.8 and S1.11.2.11.

S1.8.3 Output—The electrical signal output of the transducer shall be dc, directly proportional to the pressure or differential pressure input. The output shall be a true current source or true voltage source.

S1.8.3.1 Current Output—When a 4- to 20-mA current output is specified (see S1.5.2), the requirements specified herein shall be met regardless of external load resistance variations over a range from 0 to 250 Ω. The 4-mA output shall correspond to the lower pressure or differential pressure range value, and the 20-mA output shall correspond to the upper pressure or differential pressure range value for the ranges specified in Table S1.1.

S1.8.3.2 Voltage Output—When a voltage output is specified (see S1.5.2), the requirements specified herein shall be met for external load resistance exceeding 100 000 Ω. The 0-V output shall correspond to the lower pressure or differential pressure range value, and the 5-V, 12-V, 3-mV, and 200-µV output shall correspond to the upper pressure or differential pressure range value for the ranges specified in Table S1.1.

S1.8.4 Transducer Performance—Unless otherwise specified, performance tolerances are specified in percent of transducer output span.

S1.8.4.1 Static Error Band—The transducer static error band shall not exceed ±0.5 %.

S1.8.4.2 Output—The output shall conform to S1.8.3, and the transducer performance shall be within the static error band specified in S1.8.4.1.
S1.8.4.3 Warm-Up Time—The transducer output shall attain a value within ±0.5 % of the steady-state output with no overshoot in excess of 0.5 %. Output shall reach this band within 15 s after the transducer is energized and shall remain in this band.

S1.8.4.4 Enclosure—The transducer shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures.

S1.8.4.5 Repeatability—Repeatability of the transducer output shall be within 0.5 %.

S1.8.4.6 Sensitivity Factor—The sensitivity factor shall not be less than 0.75 nor more than 1.25.

S1.8.4.7 Ripple—The transducer root mean square (rms) output ripple shall not exceed 0.15 % of full-scale dc output.

S1.8.4.8 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The maximum difference between outputs at any voltage and frequency or voltage (for dc) condition and the normal (115-V, 60-Hz, or 28-Vdc) at the same input and test temperature (differential pressure shall be included for Type D) shall not exceed 0.5 %.

S1.8.4.9 Common Mode Pressure (Type D Only)—During the common mode pressure test, transducer performance shall be within the range formed by extending the upper and lower static error band limits specified in S1.8.4.1 by a percentage equal to the following:

\[
\frac{1}{10} \text{system pressure rating} \times \frac{1}{10} \text{differential pressure range}
\]

S1.8.4.10 Response—Transducer output shall conform to the following criteria, where all percentages are of transducer span:

1. The transducer output shall be within ±2 % of the maximum ramp pressure within 0.01 s of the time that pressure is attained.
2. The transducer output shall exhibit no overshoot of maximum ramp pressure in excess of 2 %.
3. The transducer output shall indicate the actual pressure to within ±1 % in 0.175 s or less after attainment of the maximum ramp pressure, and shall remain within this error band for the duration of the applied steady-state pressure.

S1.8.4.11 Transient Supply Voltage and Frequency (ac) or Supply Voltage (dc):

1. Voltage—During the transient test, the transducer output shall remain within ±0.5 % of the pretransient output.
2. Frequency—During the frequency transient test, the transducer output shall remain within ±0.5 % of the steady-state output.

S1.8.4.12 Temperature—During the temperature test, the transducer performance shall be within the static error band specified in S1.8.4.1.

S1.8.4.13 Overpressure—The calibration conducted after the overpressure test shall have no values in excess of 1 % deviation from the pre-overpressure test reference measurement.

S1.8.4.14 Line Pressure (Type D Only)—After the line pressure test, the transducer performance shall be within the static error band specified in S1.8.4.1.

S1.8.4.15 Pressure Cycling—The calibration conducted after completion of pressure cycling test shall have no values in excess of 1 % deviation from pretest reference measurement.

S1.8.4.16 Insulation Resistance—The insulation resistance of the transducer shall be not less than 10 MΩ.

S1.8.4.17 Vibration—Monitored transducer output during all phases of vibration test shall show no variation from steady-state output in excess of 2 %. There shall be no visible evidence of damage to the transducer as a result of the vibration test.

S1.8.4.18 Shock—The transducer shall operate during and after the shock test. After the shock test, the transducer output shall have no value in excess of 1 % deviation from the preshock test reference measurement. There shall be no visual evidence of damage to the transducer as a result of the shock test.

S1.8.4.19 Burst Pressure—The transducer shall withstand the burst pressure specified in S1.11.2.19 without showing any evidence of leakage.

S1.8.4.20 Electromagnetic Interference (EMI)—The transducers shall meet the requirements of Table II of MIL-STD-461, except as modified as follows:

1. CE101—The test signal shall be applied only to the ac power leads of the test sample.
2. CE102—The test signal shall be applied only to the ac power leads of the test sample.
3. CS114—Only Limit Curve #2 shall apply with the frequency range limited from 10 kHz to 30 MHz.
4. RE101—Only the limit curve for 50 cm shall apply.
5. RS103—The frequency range shall be limited from 10 kHz to 18 GHz with an electric field strength test level of 10 V/m.

S1.9 Workmanship, Finish, and Appearance

S1.9.1 Transducer Cleaning—The manufacturer shall ensure that pressure transducers shall be free of all loose scale, rust, grit, filings, and other foreign substances and free of mercury, oil, grease, or other organic materials. In addition, the following shall apply:

1. Transducers for oxygen service, Application X (see S1.4.3), shall be clean gas calibrated, cleaned, and pressure connections capped.
2. Transducers for all other applications shall be freshwater or clean gas calibrated, cleaned, and pressure connections capped.

S1.10 Number of Tests and Retests

S1.10.1 The number of test specimens to be subjected to first-article and conformance tests shall depend on the transducer design. If each range is covered by a separate and distinct design, a test specimen for each range shall require testing. In instances in which a singular design series may cover multiple ranges and types, only three test specimens need be tested provided the electrical and mechanical similarities are approved by the purchaser. In no case, however, shall less than three units, one unit each representing the low, medium, and high ranges, be tested, regardless of design similarity.

S1.10.1.1 Low Range—Less than 700 kPa (less than 100 lb/in.²).
S1.10.1.2 Medium Range—700 kPa to less than 7 MPa (100 to less than 1000 lb/in.²).
S1.10.1.3 High Range—7 MPa and greater (1000 lb/in.² and greater).
S1.11 Test Methods

S1.11.1 Test Conditions—Except where the following factors are the variables, the tests specified in S1.11.2 shall be conducted with the equipment under the following operating environmental conditions:

S1.11.1.1 Ambient temperature shall be 23 ± 2°C.
S1.11.1.2 Relative humidity shall be ambient.
S1.11.2 Tests—Except for the warm-up time test (see S1.11.2.3), the transducer and all associated test equipment shall be energized for a period of time sufficient to ensure complete warm-up.

S1.11.2.1 Reference Measurement—A reference measurement consisting of one-trial calibration with at least five equally spaced intervals over the entire transducer range both upscale and downscale shall be conducted when specified in the individual test.

S1.11.2.2 Output—A reference measurement shall be made in accordance with S1.11.2.1. Performance shall conform to the requirements of S1.8.4.2.

S1.11.2.3 Warm-Up Time—The test shall be conducted to determine the elapsed time between the application of line power to the transducer and the point at which the transducer output reaches the conditions specified in S1.8.4.3.

S1.11.2.3.1 Test Conditions—The transducer shall be subjected to the ambient temperature of the testing location, while deenergized, for not less than 2 h. Recording equipment and other auxiliary equipment shall be energized to ensure complete warm-up. An input pressure (differential pressure for Type D) of 80 ± 5 % of the transducer span shall be applied to the transducer and maintained constant during this test. Performance shall conform to S1.8.4.

S1.11.2.4 Enclosure—The enclosure shall be subjected to the tests in NEMA Standard 250 for Type 4X enclosures. Performance shall conform to S1.8.4.4.

S1.11.2.5 Static Error Band and Repeatability—The transducer shall first be flexed over its full-pressure range by slowly increasing and decreasing the applied pressure for six continuous cycles. The calibration measurement shall be made at a minimum of five equally spaced intervals over the entire range (both upscale and downscale). Precaution shall be taken to avoid overshoot. This calibration procedure shall be applied three successive times to determine repeatability. Static error band of all calibrations shall meet the requirements of S1.8.4.1. Repeatability shall meet the requirements of S1.8.4.5.

S1.11.2.6 Sensitivity Factor—The sensitivity factor shall be determined as follows: Provide a pressure (differential pressure for Type D) to the transducer to a level of 80 ± 5 % of span. Record the input pressure (differential pressure) and corresponding electrical output. Increase the pressure (differential pressure) by an amount not exceeding 1 % of span. Record both the new pressure (differential pressure) and corresponding new electrical output. Calculate the change in both applied pressure (differential pressure) and electrical output as a percentage of transducer span. Determine the ratio of electrical output percentage change to applied pressure (differential pressure) percent change. Repeat this procedure for a pressure (differential pressure) decrease not exceeding 1 % of span. Performance shall conform to the requirements of S1.8.4.6.

S1.11.2.7 Ripple—Transducer output root mean square ripple shall be determined at an input pressure (differential pressure for Type D) of 80 ± 5 % of transducer span. Performance shall conform to the requirements of S1.8.4.7.

S1.11.2.8 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The transducer shall be operated at normal, maximum, and minimum steady-state voltages (dc) and at all possible combinations of normal, maximum, and minimum voltages and frequencies (ac). The ambient temperature shall also vary, with the transducer operated for at least 15 min at each test temperature before the first reference measurement. The transducer shall be allowed at least 15 min to stabilize at each configuration at which point a reference measurement shall be taken (see S1.11.2.1). Reference measurements shall be performed at ambient temperatures of 0 ± 2, 25 ± 2, and 65 ± 2°C. Test temperatures shall be accomplished by varying temperature in steps of 10°C each (30 min for each step) until the desired ambient temperature is reached. Performance shall conform to S1.8.4.8.

S1.11.2.9 Common Mode Pressure (Transducer Type D Only)—The rated pressure of the transducer shall be applied simultaneously to both pressure ports. The pressure at the low-pressure port shall then be decreased in pressure increments specified in S1.11.2.1 to the specified transducer range and then increased in similar increments to the transducer-rated pressure. Performance shall conform to S1.8.4.9.

S1.11.2.10 Response—A pressure (differential pressure for Type D) ramp consisting of a pressure (differential pressure for Type D) rise of at least 40 % of transducer span occurring at a rate of not less than 400 %/s shall be applied to the transducer operating at the upper and lower limits of steady-state frequency, a transient voltage of no more than ±16 %, recovering to the steady-state band in 2 s, superimposed. With the transducer operating at the upper and lower limits of steady-state ac voltage, the ac-powered transducer shall have a transient voltage of no more than ±16 %, recovering to the steady-state band in 2 s, superimposed. With the transducer operating at the upper and lower limits of steady-state dc voltage, the dc-powered transducer shall have a transient voltage of no more than ±2 V, respectively, recovering to the steady-state band in 2 s, superimposed. Performance shall conform to the requirements of S1.8.4.11.

I) Transient Voltage:

(a) Upper and Lower Limits of Steady-State Voltage—With the transducer operating at the upper and lower limits of steady-state ac voltage, the ac-powered transducer shall have a transient voltage of no more than ±16 %, recovering to the steady-state band in 2 s, superimposed. With the transducer operating at the upper and lower limits of steady-state dc voltage, the dc-powered transducer shall have a transient voltage of no more than ±2 V, respectively, recovering to the steady-state band in 2 s, superimposed. Performance shall conform to the requirements of S1.8.4.11.

(b) Lower Limit of Steady-State Frequency—With the transducer operating at the lower limit of steady-state frequency, a transient frequency of +1.5 Hz recovering to the steady-state
band in 2 s shall be superimposed. Performance shall conform to the requirements of S1.8.4.11.

S1.11.2.12 Temperature—The transducer shall operate normally (without alignment or adjustment) throughout the following temperature cycle. Tolerances in operating characteristics shall be as specified herein.

1. Hold the test temperature at 0 ± 2°C for at least 24 h.
2. Increase the test temperature in steps of 5°C each, at 30 min for each step, until +65 ± 2°C is reached and hold at that temperature for at least 4 h.
3. Reduce the test temperature in steps of 5°C each, at 30 min for each step, until +25 ± 2°C is reached and hold at that temperature for at least 4 h. At each temperature plateau (0, 65, and 25°C), a reference measurement (see S1.11.2.1) shall be made. Performance shall conform to S1.8.4.12.

S1.11.2.13 Overpressure—Before the overpressure test, a reference measurement in accordance with S1.11.2.1 shall be made. The transducer shall successfully withstand pressure (differential pressure for Type D) equal to 200 % of its range with a maximum pressure of 85 MPa (12 000 lb/in.²) for a period of ½ h. At the end of this period, transducers shall be immediately subjected to a pressure equal to 7 kPa (1 lb/in.²) or 10 % of range, whichever is less, below atmospheric for an additional period of ½ h. Within 10 min after release of this pressure, a reference measurement (see S1.11.2.1) shall be made for comparison. Performance shall conform to S1.8.4.13.

For Type D only, if the line pressure rating exceeds 200 % of the differential pressure range, the overpressure test shall be omitted and 0.5 % deviation shall be applied to the line pressure test (see S1.11.2.14).

S1.11.2.14 Line Pressure (for Type D Only)—The transducer shall successfully withstand the pressure rating, when applied to the high-pressure port with the low-pressure port vented to atmosphere for a period of 10 min. The preceding shall be repeated with the pressure applied to the low-pressure port of the transducer. After each test, a reference measurement in accordance with S1.11.2.1 shall be made. Performance shall conform to S1.8.4.14.

S1.11.2.15 Pressure Cycling—Before performing the pressure cycling test, a reference measurement shall be made (see S1.11.2.1). The test shall be conducted on a suitable system by applying a periodic pressure change of not more than 20 % to not less than 80 % of span for a total of 260 000 cycles. The rate of cycling shall be within the range from 0.25 to 2 Hz. The transducer shall be energized throughout the test. After completion of the pressure cycling test, a reference measurement shall be made for comparison (see S1.11.2.1). Performance shall conform to S1.8.4.15.

S1.11.2.16 Insulation Resistance—The insulation resistance of the transducer shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The relative humidity shall be 50 ± 10 %. The insulation resistance measurement shall be made immediately after a 2-min period of uninterrupted test voltage application. However, if the indication of insulation resistance meets the specified limit (see S1.8.4.16) and is steady or increasing, the test may be terminated before the end of the 2-min period.
test which may be conducted on separate transducers, the test specimens (transducers) shall be subjected to the tests specified in Table S1.4 in the order listed. Deviation of the test order shall be approved by the purchaser.

S1.12.3 Conformance Tests—Each pressure transducer in each lot offered for delivery shall be subjected to the tests listed in Table S1.5 and shall be conducted in the order listed. Failure of any pressure transducer to meet the requirements of this specification shall be cause for rejection.

S1.12.4 General Examination—Each transducer shall be given a thorough examination to determine conformance to the requirements of this specification with respect to material, finish, workmanship, construction, assembly, dimensions, weight, and marking of identification. Examination shall be limited to the examinations that may be performed without disassembling the units. The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with applicable approved industry standards.

S1.13 Certification

S1.13.1 The purchase order or contract should specify whether the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. The purchase order or contract should specify when a report of the test results shall be furnished. Otherwise, the purchase order or contract should specify that all test data remain on file for three years at the manufacturer’s facility for review by the purchaser upon request.

S1.14.1 Label Plates—A label plate with engraved or stamped markings shall be permanently affixed to the transducer. At a minimum, it shall contain the following: S1.14.1.1 "PRESSURE TRANSDUCER" or "DIFFERENTIAL PRESSURE TRANSDUCER."

S1.14.1.2 Manufacturer’s name,
S1.14.1.3 National Stock Number (NSN), if available,
S1.14.1.4 Date of manufacture,
S1.14.1.5 Designation, and
S1.14.1.6 Pressure rating for Type D transducers.
S1.14.2 Transducers for use with Applications F and X (see S1.4.3) shall have “USE NO OIL FOR CALIBRATION” prominently marked on the body.

S1.14.3 For Type D transducers, the high- and low-pressure connections shall be clearly marked on the transducer body adjacent to the connections.

S1.14.4 The legend "DO NOT LUBRicate" shall be prominently marked on the body.

S1.15 Packaging and Package Marking

S1.15.1 Packaging and package marking shall be in accordance with Section 15.

S1.16 Quality Assurance

S1.16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see S1.5.2).

S1.16.2 Warranty—Any special warranty requirements shall be specified in the acquisition requirements (see S1.5.2). The following supplementary requirement, established for U.S. naval shipboard application, shall apply when specified in the contract or purchase order. When there is conflict between this specification and this supplementary requirement, this supplementary requirement shall take precedence. This document supersedes MIL-S-24796, Sensors, Absolute Pressure, Fiber Optic (Naval Shipboard Use), for new ship construction.

S2. TRANSDUCERS, PRESSURE AND DIFFERENTIAL PRESSURE, FIBER-OPTIC

S2.1 Scope

S2.1.1 This supplement covers the requirements for fiber-optic pressure transducers designed to meet the requirements for use onboard naval ships.

S2.1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are provided for information only. Where information is to be specified, it shall be stated in SI units.

S2.2 Referenced Documents

S2.2.1 ASTM Standards:
D 542 Test Methods for Index of Refraction of Transparent Organic Plastics
D 570 Test Method for Water Absorption of Plastics
S2.2.2 EIA Standard:
TIA-422 Electrical Characteristics of Balanced Voltage Digital Interface Circuits

---

7 Annual Book of ASTM Standards, Vol 08.01.
S2.2.3 ISO Standard:
6149-1 Connections for Fluid Power and General Use—Ports and Stud Ends with ISO 261 Threads and O-Ring Sealing—Part 1: Port with O-Ring Seal in Truncated Housing

S2.2.4 NEMA Standard:
250 Enclosures for Electrical Equipment (1000 Volts Maximum)

S2.2.5 Military Standards:
MIL-PRF-49291 Fiber, Optical (Metric), General Specification for
MIL-S-901 Shock Tests, H.I. (High-Impact); Shipboard Machinery, Equipment and Systems, Requirements for
MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment (Type I—Environmental and Type II—Internally Excited)
MIL-STD-461 Electromagnetic Interference Characteristics of Subsystems and Equipment, Requirements for the Control of
MIL-STD-1399, Section 300 Interface Standard for Shipboard Systems, Electric Power, Alternating Current
MS3452 Connector, Receptacle, Electric, Box Mounting, Rear Release, Crimp Contact, AN Type
MS3456 Connector, Plug, Electrical, Rear Release, Crimp Contact, AN Type

S2.3 Terminology
S2.3.1 Terminology is consistent with that of Section 3 and the referenced documents.

S2.4 Classification
S2.4.1 Designation—For this specification, fiber-optic pressure transducer designations shall be assigned in accordance with S2.5.1 and listed in the following format:

Example: F25FXMS2-P-F-X-AC-A-N-1-P-100A

S2.4.2 Type—The following designators have been established for the various types of fiber-optic transducers:
D—Pressure, differential
P—Pressure (gage, sealed, absolute)
V—Pressure, vacuum
C—Pressure, compound

S2.4.3 Application—The following application designations have been established for the media to be measured:
F—Freshwater, oil, condensate, steam, nitrogen, and other inert gases
S—Seawater
G—Flue gas and ammonia
X—Oxygen

S2.4.4 Pressure Rating—The pressure rating shall be indicated by the designator for its numerical value for Type D transducers ("X" for Type P, V, and C transducers) and shall be limited to the following:

<table>
<thead>
<tr>
<th>Designator</th>
<th>Rating, kPaG</th>
<th>Inch-Pound Units, psig</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>100</td>
<td>15</td>
</tr>
<tr>
<td>2</td>
<td>1000</td>
<td>150</td>
</tr>
</tbody>
</table>

S2.4.5 Power Supply—Transducers shall operate with either ac or dc input power, but not both. Designators shall be as follows:
S2.4.5.1 dc—Direct current supply.
S2.4.5.2 ac—Alternating current supply.
S2.4.6 Output—The prime output shall be an electrical dc signal. A supplemental output shall also be provided when specified. The signal output of the transducer shall be designated by the following designators:
A—4 to 20 mA
V—0 to 5 V
O—Optical (and current)
D—Digital (and current)

S2.4.7 Pressure Connection—Transducer pressure sensing connection shall be as follows:
N—M12 × 1.5 (1/4-20 UNF-2B) (see S7.5)
X—1/4 nps, 155-mm (6-in.) long pipe nipple (see S7.5)
Z—Other

S2.4.8 Optoelectronics Module—The optoelectronics module shall be designated as follows:
1—Bulkhead mounted
2—Console mounted

S2.4.9 Transducer Mounting—The transducer mounting method shall be designated as follows:
P—Pressure port connection
M—Mounting plate

S2.4.10 Range—The pressure range of the transducer shall be designated by two parts. The first part shall be the designator for the upper range value. The second part shall be the designator for the upper range unit of measure (see S2.4.8.1). The transducer pressure ranges shall be in accordance with Table S2.1.

S2.4.10.1 Units—The units shall be designated by the corresponding letter designator and are limited to the following:

<table>
<thead>
<tr>
<th>Letter</th>
<th>SI Units</th>
<th>Inch-Pound Units</th>
</tr>
</thead>
<tbody>
<tr>

S2.5 Ordering Information
S2.5.1 The purchaser shall provide the manufacturer with all of the pertinent application data in accordance with S2.5.2. If special application operating conditions exist that are not in the acquisition requirements, they shall also be described.

S2.5.2 Acquisition Requirements—Acquisition documents shall specify the following:
S2.5.2.1 Title, number, and date of this specification.
S2.5.2.2 Part designation required (see S2.4.1).
S2.5.2.3 National Stock Number (NSN), if available.
S2.5.2.4 Transducer mounting method, if other than specified herein (see S2.7.2).
S2.5.2.5 Optoelectronics module mounting method, if other than specified herein (see S2.7.2).
S2.5.2.6 Type of pressure connection, if other than specified herein (see S2.7.7).
S2.5.2.7 Type of electrical connection, if other than specified herein (see S2.7.6).
S2.5.2.8 When the electrical connection mating plug is not to be provided (see S2.7.6).
S2.5.2.9 Requirements when Type 2 optoelectronics module is specified (see S2.7.2).
S2.5.2.10 Fiber-optic cable length required (see S2.7.3).
S2.5.2.11 Output requirements when Type O output is specified (see S2.8.3.3) or output requirements and data format when Type D output is specified (see S2.8.3.4).
S2.5.2.12 Electrical connectors when Type D output is specified (see S2.7.6).
S2.5.2.13 When overload protection is required for the optoelectronics module (see S2.7.9).
S2.5.2.14 Quantity of transducers required.
S2.5.2.15 When first-article tests are required (see S2.12.3).
S2.5.2.16 Group B inspection sample size (see S2.12.3.2).
S2.5.2.17 Special product marking requirements (see S2.14).
S2.5.2.18 Special packaging or package marking requirements (see S2.15).
S2.5.2.19 When ISO 9001 quality assurance system is not required (see S2.16.1).
S2.5.2.20 Special warranty requirements (see S2.16.2).

First-Article Tests—When first-article tests are required, the purchaser should provide specific guidance to offerors whether the item(s) should be a preproduction sample, a first-article sample, a first production item, a sample selected from the first production items, or a standard production item from the manufacturer’s current inventory. The number of items to be tested in accordance with S2.12.4 should be specified. The purchaser should also include specific instructions in acquisition documents regarding arrangements for tests, approval of first-article test results and time period for approval, and disposition of first articles. Invitations for bids should provide that the purchaser reserves the right to waive the requirement for samples for first-article testing to those manufacturers offering a product that has been previously

acquired or tested by the purchaser, and that manufacturers offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior purchaser approval is presently appropriate for the pending contract. The manufacture of items before purchaser approval should be specified as the responsibility of the manufacturer.

S2.6 Materials

S2.6.1 Metals—Unless otherwise specified herein, all metals used in the construction of the transducer shall be corrosion resistant. Dissimilar metals shall not be used in contact with each other unless suitably finished to prevent electrolytic corrosion. The materials for the wetted parts shall be selected for long-term compatibility with the process medium.

S2.6.2 Flammable Materials—Materials used in the construction of the transducer shall in the end configuration be noncombustible or fire retardant in the most hazardous conditions of atmosphere, pressure, and temperature to be expected in the application. Fire retardance shall not be achieved by use of nonpermanent additives to the basic material.

S2.6.3 Fungus-Resistant Materials—Materials used in the construction of the transducer shall not support the growth of fungus.

S2.6.4 Solvents, Adhesives, and Cleaning Agents—When chemicals or cements are used in bonding of internal transducer components, no degradation shall result during in-service use.

S2.6.5 Refractive Index Matching Gels, Fluids, or Compounds—Refractive index matching gels, fluids, or compounds shall not produce toxic, corrosive, or explosive by-products. The material is subject to a toxicological data and formulations review and inspection, for safety of material, by the purchaser. The index matching material shall be either silicone or aliphatic hydrocarbon material and shall be clear and transparent. The index matching material shall have an index of refraction of $1.46 \pm 0.01$ as tested in accordance with Test Methods D 542, when exposed to operating temperature extremes between $-28$ and $+85^\circ$C. The index matching material shall not flow at elevated temperatures. The index matching material shall remain clear and transparent when tested for water absorption in accordance with Test Method D 570. The index matching material shall have a shelf life not less than 36 months at $25 \pm 5^\circ$C. The 36-month period commences on the date of adhesive manufacture.

S2.7 Physical Properties

S2.7.1 Sensor Head Configuration—The sensor head shall be constructed in accordance with configuration limits in Fig. S2.1. When required for repair or maintenance, replacement of sensor head components shall be accomplished with the sensor head body remaining fixed in place at mounting plate and pressure connection points.

S2.7.1.1 Sensor Head Mounting—The sensor head shall be mounted using mounting holes in locations shown in Fig. S2.1. If required in a specific application and with prior approval of the purchaser, the sensor head may be mounted by its pressure piping connection (see S2.5.2). For Type D transducers, the high-pressure port shall be used. If the sensor head is mounted

Note 1—Sensor head housing (body) cross section is shown as circular. Any alternate cross section not exceeding 50 mm (2 in.) in width and 50 mm (2 in.) in height is acceptable.

Note 2—Dimension tolerance is plus or minus 1.25 mm (0.05 in.), unless otherwise specified.

Note 3—The pressure connection(s) shall be generally located as shown.

FIG. S2.1 Sensor Head External Configuration
by its pressure connection, mounting holes shall not be required. It is recommended that the sensor head be installed such that sufficient clearance is provided for repair and maintenance of the unit.

S2.7.2 Optoelectronics Module—The optoelectronics module shall contain the optical and signal conditioners needed to convert the sensor head output to the specified transducer output signal. Access to the interior of the optoelectronics module shall be possible to replace the connectorized cable. The module shall be bulkhead mounted or console mounted as specified in acquisition requirements (see S2.5.2).

S2.7.2.1 Bulkhead Mounted (Type 1)—The optoelectronics module shall be housed in a NEMA Standard 250 Type 4 enclosure.

S2.7.2.2 Console Mounted (Type 2)—The optoelectronics module shall be packaged in a console-mounted circuit card as specified in acquisition requirements (see S2.5.2).

S2.7.2.3 Fiber-Optic Cable—A fiber-optic cable shall be used to connect the sensor head to the optoelectronics module. There shall be no less than two times the number of fibers needed for operation of the transducer in the cable. Penetration of the fiber-optic cable into both the sensor head and the optoelectronics module shall be watertight. The required length of cable shall be as specified in acquisition requirements (see S2.5.2).

S2.7.4 Optical Fiber—All optical fiber used in the construction of the transducer shall be in accordance with MIL-PRF-49291.

S2.7.5 Fiber-Optic Connectors, Receptacles, and Bulkhead Adapters—All fiber-optic connectors, receptacles, and bulkhead adaptors shall be in accordance with MIL-C-83522 and MIL-C-83522/16, 17, and 18, respectively, or equivalent. Connectors shall be assembled at both ends of the fiber-optic cable between the sensor head and the optoelectronics module. The connectors and receptacles shall be mounted inside the sensor head and optoelectronics module.

S2.7.6 Electrical Connector—An electrical interface connector receptacle and mating plug shall be provided with each optoelectronics module of the transducer unless otherwise specified. The electrical connector shall be a standard threaded coupling receptacle, AN type, MS3452W/14S-5P, or equivalent, for dc-power input, or AN type, MS3452W/14S-5PX, or equivalent, for ac-power input. The mating plug shall be a MS3456W/14S-5S, or equivalent, for dc-power input, or MS3456W/14S-5SX, or equivalent, for ac-power input. Electrical connectors for digital output shall be as specified (see S2.5.2).

S2.7.6.1 dc-Power Input—Current Output—The receptacle shall be wired to provide the performance described herein. Receptacle Pin A shall be +28-Vdc power input, Pin B shall be –28-Vdc power input, and Pin C shall be case ground. Receptacle Pins A and B shall also serve as the 4-20-mA dc signal output.

S2.7.6.2 dc-Power Input—Voltage Output—The receptacle shall be wired to provide the performance described herein. Receptacle Pin A shall be +28-Vdc power input, Pin B shall be –28-Vdc power input, Pin C shall be case ground, Pin D shall be +0-5-Vdc signal output, and Pin E shall be –0-5-Vdc signal output.

S2.7.6.3 ac-Power Input—Current Output—The receptacle shall be wired to provide the performance described herein. Receptacle Pins A and B shall be 115-Vac power input. Pin C shall be case ground, Pin D shall be +4-20-mA dc signal output, and Pin E shall be –4-20-mA dc signal output.

S2.7.6.4 ac-Power Input—Voltage Output—The receptacle shall be wired to provide the performance described herein. Receptacle Pins A and B shall be 115-Vac power input, Pin C shall be case ground, Pin D shall be +0-5-Vdc signal output, and Pin E shall be –0-5-Vdc signal output.

S2.7.7 Pressure Connections—Unless otherwise specified, transducer pressure-sensing connections for all services shall be M12 × 1.5 (7/32 UNF-2B) tube connection in accordance with ISO 6149-1. When pressure connection Type X is specified, as commonly used on submarine oxygen replenishment systems, the transducer sensing connections shall be a nickel-copper pipe nipple ¼ nominal pipe size (nps) with 3.1-mm (0.12-in.) minimum wall thickness, 155 mm (6 in.) long, welded to the socket (see S2.5.2). For Type D transducers, the high-pressure connection shall be on the end and the low-pressure connection shall be on the side (see Fig. S2.1).

S2.7.8 Adjustments—Tamper-proof adjustments for zero and span may be provided on the optoelectronics module for calibration purposes. The number of adjustments shall be kept to a minimum consistent with the operation and maintenance requirements. Electrical disconnection shall not be required to accomplish these adjustments.

S2.7.9 Electrical Overload Protection and Isolation—The optoelectronics module shall be provided with overload protection when not adequately protected by the ship’s power circuits (see S2.5.2). A means of isolating the optoelectronics module from ship power shall be provided on the unit.

S2.7.10 Calibration Media—Oil shall not be used as the calibration media.

S2.7.11 Welding—For Application X, all pressure boundary joints shall be welded.

S2.7.12 Lubrication—The transducer shall not require lubrication.

S2.7.13 Damping—The use of oil for damping is prohibited.

S2.7.14 Weight—The weight of the sensor head shall not exceed 510 g (18 oz). The weight of the optoelectronics module shall not exceed 4.5 kg (10 lb).

S2.8 Performance Requirements

S2.8.1 Service Life—The transducer shall be constructed for a service life of no less than 40 000 h and shall meet the requirements specified herein when operated in the naval shipboard environment.

S2.8.2 Input Power—The transducer shall be designed to operate using 115-V, 60-Hz, single-phase, ungrounded, ac power as defined in MIL-STD-1399, Section 300 or 28 ± 4.5-V dc power. The transducer shall operate with power supply variations as specified in S2.11.2.7 and S2.11.2.8.

S2.8.3 Output—The prime transducer output shall be an electrical dc signal that is directly proportional to the input
pressure and shall be a true current or voltage source. If an optical or digital output is required, it shall be a supplemental output.

S2.8.3.1 Current Output—When a 4- to 20-mA current output is specified (see S2.5.2), the requirements specified herein shall be met regardless of external load resistance variations over a range from 0 to 250 $\Omega$. The output shall be directly proportional to the input pressure. The 4-mA output shall correspond to the lower pressure range value and the 20-mA output shall correspond to the upper pressure range value for the ranges specified in Table S2.1.

S2.8.3.2 Voltage Output—When a 0- to 5-V output is specified (see S2.5.2), the requirements specified herein shall be met for external load resistance exceeding 100 000 $\Omega$. The output shall be directly proportional to the input pressure. The 0-V output shall correspond to the lower pressure range value, and the 5-V output shall correspond to the upper pressure range value for the ranges specified in Table S2.1.

S2.8.3.3 Optical Output—When an optical output is specified (see S2.5.2), the optical output requirements shall be as specified in the ordering data (see S2.5.2).

S2.8.3.4 Digital Output—When an electrical digital output is specified (see S2.5.2), the digital output requirements shall be as specified in the ordering data (see S2.5.2). The electrical characteristics shall be in accordance with EIA Standard TIA-422 for balanced voltage digital interface circuitry, or as specified (see S2.5.2). The data format shall be as specified (see S2.5.2).

S2.8.4 Transducer Performance—Unless otherwise specified, performance tolerances are specified in percent of transducer output span.

S2.8.4.1 Static Error Band—The transducer static error band shall not exceed $\pm 1\%$.

S2.8.4.2 Repeatability—Repeatability of the transducer output shall be within $0.5\%$.

S2.8.4.3 Sensitivity Factor—The sensitivity factor shall not be less than 0.75 nor more than 1.25.

S2.8.4.4 Response—The transducer output shall conform to the following criteria, where all percentages are of transducer span:

1. The transducer output shall be within $\pm 2\%$ of the maximum ramp pressure within 0.01 s of the time that pressure is attained.

2. The transducer output shall exhibit no overshoot of maximum ramp pressure in excess of 2 %.

3. The transducer output shall indicate the actual pressure to within $\pm 1\%$ in 0.2 s or less after attainment of maximum ramp pressure, and shall remain within this error band for the duration of applied steady-state pressure.

S2.8.4.5 Warm-Up Time—The transducer output shall attain a value within $\pm 1\%$ of the steady-state output with no overshoot in excess of 1 %. Output shall reach this band within 1 min after the transducer is energized and shall remain in this band.

S2.8.4.6 Ripple—The transducer rms output ripple shall not be greater than 0.5 %.

S2.8.4.7 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The maximum difference between outputs at any voltage and frequency or voltage (for dc) condition and the normal (115-V, 60-Hz, or 28-V dc) at the same input and test temperature (differential shall be included for Type D) shall not exceed 1 %.

S2.8.4.8 Transient Supply Voltage and Frequency (ac) or Supply Voltage (dc):

S2.8.4.8.1 Voltage—During the voltage transient test, the transducer output shall remain within $\pm 0.5\%$ of the pre-transient output.

S2.8.4.8.2 Frequency—During the frequency transient test, the transducer output shall remain within $\pm 0.5\%$ of the pre-transient output.

S2.8.4.9 Power interruption—During the power interruption test, the transducer performance shall conform to S2.8.4.1.

S2.8.4.10 Common Mode Pressure (Type D Only)—During the common mode pressure test, transducer performance shall be within the range formed by extending the upper and lower static error band limits specified in S2.8.4.1 by a percentage equal to:

\[
\frac{1}{10} \times \text{(system pressure rating)} \times \frac{1}{3} \times \text{differential pressure range}
\]

S2.8.4.11 Temperature—During the temperature test, the transducer performance shall be within the static error band specified in S2.8.4.1.

S2.8.4.12 Enclosure—The sensor head and optoelectronics module shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures.

S2.8.4.13 Overpressure—Calibration conducted after over-pressure test shall have no values in excess of 1 % deviation from the pre-over-pressure test reference measurement.

S2.8.4.14 Line Pressure (Type D Only)—After the line pressure test, transducer performance shall be within the static error band specified in S2.8.4.1.

S2.8.4.15 Pressure Cycling—Calibration conducted after completion of pressure cycling test shall have no values in excess of 1 % deviation from pre-test reference measurement.

S2.8.4.16 Vibration—Monitored transducer output during all phases of the vibration test shall show no variation from steady-state output in excess of 2 %. There shall be no visible evidence of damage to the transducer as a result of the vibration test.

S2.8.4.17 Shock—The transducer shall operate during and after the shock test. After the shock test, the transducer output shall have no value in excess of 1 % deviation from the pre-shock test reference measurement. There shall be no visual evidence of damage to the transducer as a result of the shock test.

S2.8.4.18 Burst Pressure—The transducer shall withstand the burst pressure specified in S2.11.2.19 without showing any evidence of leakage.

S2.8.4.19 Short-Circuit (Output Type A Only)—After the short-circuit test, the transducer shall exhibit no damage and shall conform to S2.8.4.1.

S2.8.4.20 Line Voltage Reversal (dc Power Supply Only)—The transducer shall conform to S2.8.4.1 after the line voltage reversal test.

S2.8.4.21 Insulation Resistance—The insulation resistance of the transducer shall be not less than 10 M$\Omega$. 

---

**F 2070 – 00**
S2.8.4.22 Electromagnetic Interference (EMI) Emission and Susceptibility—The transducers shall meet the requirements of Table II of MIL-STD-461, except as modified as follows:

1. CE101—The test signal shall be applied only to the ac-power leads of the test sample.
2. CE102—The test signal shall be applied only to the ac-power leads of the test sample.
3. CS114—Only Limit Curve #2 shall apply with the frequency range limited from 10 kHz to 30 MHz.
4. RE101—Only the limit curve for 50 cm shall apply.
5. RS103—The frequency range shall be limited from 10 kHz to 18 GHz with an electric field strength test level of 10 V/m.

S2.9 Workmanship, Finish, and Appearance

S2.9.1 Transducer Cleaning—The manufacturer shall ensure that pressure transducers shall be free of all loose scale, rust, grit, filings, and other foreign substances and free of mercury, oil, grease, or other organic materials. In addition, the following shall apply:

1. Transducers for oxygen service, Application X (see S2.4.3), shall be clean gas calibrated, cleaned, and pressure connections capped.
2. Transducers for all other applications shall be freshwater or clean gas calibrated, cleaned, and pressure connections capped.

S2.9.2 Surface Finish—Surfaces of castings, forgings, molded parts, stampings, and machined and welded parts shall be free of defects such as cracks, pores, undercuts, voids, and gaps. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn through, warpage, or dimensional change as a result of heat from welding. There shall be no damage to adjacent parts resulting from welding.

S2.10 Number of Tests and Retests

S2.10.1 Test Specimen—see 10.1.

S2.11 Test Methods

S2.11.1 Test Conditions—Except where the following factors are the variables, the tests specified in S2.11.2 shall be conducted with the equipment under the following operating environmental conditions:

1. Ambient temperature shall be 23 ± 2°C.
2. Relative humidity shall be ambient.
3. Tests—Except for the warm-up time test (see S2.11.2.5), the transducer and all associated test equipment shall be energized for a period of time sufficient to ensure complete warm-up.

S2.11.2.1 Reference Measurement—A reference measurement consisting of a one-trial calibration with at least five equally spaced intervals over the entire transducer range both upscale and downscale shall be conducted when specified in the individual test. No adjustments to the transducer are permitted during the reference measurement.

S2.11.2.2 Static Error Band and Repeatability—The transducer shall first be flexed over its full-pressure range by slowly increasing and decreasing the applied pressure for six continuous cycles. The calibration measurement shall be made at a minimum of five equally spaced intervals over the entire range (both upscale and downscale). Precaution shall be taken to avoid overshoot. This calibration procedure shall be applied three successive times to determine repeatability. Static error band of all calibration shall meet the requirements of S2.8.4.1. Repeatability shall meet the requirements of S2.8.4.2.

S2.11.2.3 Sensitivity Factor—The sensitivity factor shall be determined as follows: Provide an input pressure (differential pressure for Type D) to the transducer of 80 ± 5 % of span. Record the input pressure (differential pressure) and corresponding electrical output. Increase the pressure (differential pressure) by an amount not exceeding 1 % of span. Record both the new pressure (differential pressure) and corresponding new electrical output. Calculate the change in both applied pressure (differential pressure) and electrical output as a percentage of transducer span. Determine the ratio of electrical output percentage change to applied pressure (differential pressure) percentage change. Repeat this procedure for a pressure (differential pressure) decrease not exceeding 1 % of span. Performance shall conform to the requirements of S2.8.4.3.

S2.11.2.4 Response—A pressure (differential pressure for Type D) ramp consisting of a pressure (differential pressure for Type D) rise of at least 40 % of span occurring in not greater than 0.1 s shall be applied to the transducer. The maximum ramp pressure shall be maintained for at least 0.5 s and shall not vary by more than ±2 % of the transducer span. Performance shall conform to the requirements of S2.8.4.4.

S2.11.2.5 Warm-Up Time—The test shall be conducted to determine the elapsed time between the application of the line power to the transducer and the point at which the transducer output reaches the conditions specified in S2.8.4.5.

1. (1) Test Conditions—The transducer shall be subjected to the ambient temperature of the testing location, while de-energized, for not less than 2 h. Recording equipment and other auxiliary equipment shall be energized to ensure complete warm-up. An input pressure of 80 ± 5 % of span shall be applied to the transducer and maintained constant during this test. Performance shall conform to the requirements of S2.8.4.

S2.11.2.6 Ripple—Transducer output rms ripple shall be determined at an output pressure (differential pressure for Type D) of 80 ± 5 % of transducer span. Performance shall conform to the requirements of S2.8.4.6.

S2.11.2.7 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The transducer shall be operated at normal, maximum, and minimum steady-state voltages (dc) and at all possible combinations of normal, maximum, and minimum voltages and frequencies (ac). The ambient temperature shall also vary, with the transducer operated for at least 1 h at each test temperature before the first reference measurement (see S2.11.2.1). Reference measurements shall be performed at ambient temperatures of 0 ± 2°C, 25 ± 2°C, and 65 ± 2°C. Test temperatures shall be accomplished by varying temperature in steps of 10°C each (30 min for each step) until the desired ambient temperature is reached. Performance shall conform to the requirements of S2.8.4.7.

S2.11.2.8 Transient Supply Voltage and Frequency (ac) or Supply Voltage (dc)—Tests shall be conducted with a pressure (differential pressure for Type D) input signal equal to 80 ± 5 % of the transducer span. The transducer output shall be
monitored throughout the test. Performance shall conform to the requirements of S2.8.4.8.

S2.11.2.8.1 Transient Voltage:

1. Upper and Lower Limits of Steady-State Voltage—With the transducer operating at the upper and lower limits of steady-state ac voltage, the ac-powered transducer shall have a transient voltage of ±16 %, recovering to the steady-state band in 2 s, superimposed. With the transducer operating at the upper and lower limits of steady-state dc voltage, the dc-powered transducer shall have a transient voltage of ±2 V, respectively, recovering to the steady-state band in 2 s, superimposed. Performance shall conform to the requirements of S2.8.4.8.

S2.11.2.8.2 Transient Frequency (for ac-Powered Transducers):

1. Upper Limit of Steady-State Frequency—With the transducer operating at the upper limit of steady-state frequency, a transient frequency of +1.5 Hz recovering to the steady-state band in 2 s shall be superimposed. Performance shall conform to the requirements of S2.8.4.8.

2. Lower Limit of Steady-State Frequency—With the transducer operating at the lower limit of steady-state frequency, a transient frequency of −1.5 Hz recovering to the steady-state band in 2 s shall be superimposed. Performance shall conform to the requirements of S2.8.4.8.

S2.11.2.9 Power Interruption—An input pressure (differential pressure for Type D) of 80 ± 5 % of span shall be applied to the transducer and maintained constant during the test. With the transducer operating within the steady-state tolerances of voltage and frequency, the external power supply shall be interrupted for an interval of 3 to 4 s. The power supply shall then be reestablished to within steady-state tolerances. The transducer shall be operated at steady-state power for 1 min. The power supply shall then be interrupted for an interval of 30 s. This cycle shall be repeated three times. Performance shall conform to the requirements of S2.8.4.9.

S2.11.2.10 Common Mode Pressure (Transducer Type D Only)—The rated pressure of the transducer shall be applied simultaneously to both pressure ports. The pressure at the low-pressure port shall then be decreased in pressure increments specified in S2.11.2.1 to the specified transducer range and then increased in similar increments to the transducer-rated pressure. Performance shall conform to the requirements of S2.8.4.10.

S2.11.2.11 Temperature—The transducer shall operate normally (without alignment or adjustment) throughout the following temperature cycle. Tolerances in operating characteristics shall be as specified herein. Performance shall conform to the requirements of S2.8.4.11.

1. Hold the test temperature at 0 ± 2°C for at least 24 h. During the last hour of operation, a reference measurement shall be made (see S2.11.2.1).

2. Increase the test temperature in steps of 10° each, at 30 min for each step, until +65 ± 2°C is reached and hold at that temperature for at least 24 h. During the last hour of operation, a reference measurement shall be made (see S2.11.2.1).

3. Reduce the test temperature in steps of 10° each, at 30 min for each step, until +25 ± 2°C is reached and hold at that temperature for at least 24 h. During the last hour of operation, a reference measurement shall be made (see S2.11.2.1).

S2.11.2.12 Enclosure—The sensor head and optoelectronics module (Type 1 only) shall be subjected to the tests in NEMA Standard 250 for Type 4X enclosures. Performance shall conform to the requirements of S2.8.4.12.

S2.11.2.13 Overpressure—Before the overpressure test, a reference measurement in accordance with S2.11.2.1 shall be made. The transducer shall be subjected to a pressure equal to 200 % of the upper limit of its range for a period of 30 min. Within 10 min after release of this pressure, a reference measurement (see S2.11.2.1) shall be made for comparison. Performance shall conform to the requirements of S2.8.4.13.

S2.11.2.14 Line Pressure (for Type D Only)—The transducer shall successfully withstand the pressure rating, when applied to the high-pressure port with the low-pressure port vented to atmosphere, for a period of 10 min. The preceding shall be repeated with the pressure applied to the low-pressure port of the transducer. After each test, a reference measurement in accordance with S2.11.2.1 shall be made. Performance shall conform to S2.8.4.14.

S2.11.2.15 Pressure Cycling—Before performing the pressure cycling test, a reference measurement shall be made (see S2.11.2.1). The test shall be conducted by applying a periodic pressure change of not more than 20 % of span to not less than 80 % of span for a total of 260 000 cycles. The rate of cycling shall be within the range from 0.25 to 2 Hz. The transducer shall be energized throughout the test. After completion of the pressure cycling test, a reference measurement shall be made for comparison (see S2.11.2.1). Performance shall conform to the requirements of S2.8.4.15.

S2.11.2.16 Vibration—A reference measurement (see S2.11.2.1) shall be made before the vibration test. The transducer shall be tested in accordance with Type I (environmental) vibration of MIL-STD-167-1 except that the upper frequency shall be 175 Hz; the amplitude of vibration shall be in accordance with Table S2.2; and for the variable frequency portion, the vibration level shall be maintained for two minutes at each integral value of frequency. If no resonances are observed, the 2-h endurance test shall be conducted at 175 Hz. During the vibration test, a fluid pressure of 80 ± 5 % of the transducer span shall be applied to the transducer. Transducer output during the test shall be monitored. Performance shall conform to the requirements of S2.8.4.16.

S2.11.2.17 Shock—The shock tests shall be conducted in accordance with Grade A, Class 1, Type C using bulkhead mounting fixture 4-A of MIL-S-901. During the test, a fluid pressure of 80 ± 5 % of the transducer span shall be applied to the transducer. The transducer output during the test shall be monitored. Before and after the shock test, reference measurements shall be made for comparison. Performance shall conform to the requirements of S2.8.4.18.

S2.11.2.18 Burst Pressure—The transducer shall be subjected to a liquid pressure equal to 300 % of the upper limit of its range applied to the transducer for a period of 10 min. The transducer shall conform to the requirements of S2.8.4.18. No performance test shall be required after the burst pressure test. A reference measurement (see S2.11.2.1) shall be recorded for information purposes.

S2.11.2.19 Short-Circuit (Output Type A Only)—An input pressure (differential pressure for Type D) of 80 ± 5 % of span shall be applied to the transducer and maintained constant during the test. The transducer shall be de-energized. The electrical output pins of the optoelectronics module shall be connected together with no load resistance. The transducer shall be energized for 5 min. Immediately following the 5-min period, the output pins shall be unshorted. The transducer shall conform to the requirements of S2.8.4.19.

S2.11.2.20 Line Voltage Reversal (dc Power Supply Only)—An input pressure (differential pressure for Type D) of 80 ± 5 % of span shall be applied to the transducer and maintained constant during the test. The positive 28-Vdc signal shall be applied to Connector Pin B. The dc reference signal shall be applied to Connector Pin A. The transducer shall be energized for a period of 10 min and then disconnected. The power shall then be correctly applied (Pin A positive, Pin B negative). A reference measurement shall be made (see S2.11.2.1). The transducer shall conform to the requirements of S2.8.4.20.

S2.11.2.21 Insulation Resistance—The insulation resistance of the transducer shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The relative humidity shall be 50 ± 10 %. The insulation resistance measurement shall be made immediately after a 2-min period of uninterrupted test voltage application. However, if the indication of insulation resistance meets the specified limit (see S2.8.4.21) and is steady or increasing, the test may be terminated before the end of the 2-min period.

S2.11.2.22 EMI Emission and Susceptibility—The EMI tests shall be in accordance with the test methods specified in MIL-STD-461, with the modifications as specified in S2.8.4.22. Performance shall conform to the requirements of S2.8.4.22.

S2.12 Inspection

S2.12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

S2.12.1.1 First-article tests (see S2.12.2).
S2.12.1.2 Conformance tests (see S2.12.3).

S2.12.2 First-Article Tests—First-article tests shall be performed before production. First-article tests shall be performed on samples that have been produced with equipment and procedures normally used in production. First-article tests shall consist of the examination and tests specified in Table S2.3. Failure of any pressure transducer to meet the requirements of this specification shall cause for rejection.

S2.12.2.1 First-Article Tests Sample Size—Two transducers of each lot shall be subjected to first-article testing, Table S2.3. One sample shall be subjected to the tests of Group I and one sample shall be subjected to the tests of Group II of Table S2.3. The fiber-optic connecting cable shall not be less than 100 ft.

S2.12.2.2 Order of First-Article Tests—The sample transducers shall be subjected to the tests specified in Table S2.3 in the order listed except that the steady-state supply voltage and frequency inspection may be performed concurrently with the temperature inspection. Any deviation in the test order shall first be approved by the purchaser.

S2.12.3 Conformance Tests—Each lot of transducers offered for delivery shall be subjected to the tests of Table S2.4.

S2.12.3.1 Group A Tests—All transducers offered for delivery shall be subjected to Group A tests as listed in Table S2.4. Failure of any transducer to meet the requirements of this specification shall be cause for rejection.

S2.12.3.2 Group B Tests—Group B tests shall be as listed in Table S2.4. The number of samples subjected to Group B tests shall be in accordance with Table S2.5. Failure of any transducer to meet the requirements of this specification shall be cause for rejection.

S2.12.4 General Examination—Each transducer shall be given a thorough examination to determine conformance to the requirements of this specification with respect to material, finish, workmanship, construction, assembly, dimensions, weight, and marking of identification. Examination shall be limited to the examinations that may be performed without disassembling the units. Examination shall include a check of

all adjustments, if applicable. The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with applicable approved industry standards.

S2.13 Certification
S2.13.1 The purchase order or contract should specify whether the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. The purchase order or contract should specify when a report of the test results shall be furnished. Otherwise, the purchase order or contract should specify that all test data remain on file for three years at the manufacturer’s facility for review by the purchaser upon request.

S2.14 Product Marking
S2.14.1 Label Plates—A label plate with engraved or stamped markings shall be permanently affixed to the sensor head and to the optoelectronics module.

S2.14.1.1 Sensor Head—At a minimum, the following information shall be provided on the label plate:
1. “SENSOR HEAD,”
2. Manufacturer’s name,
3. Manufacturer’s serial number,
4. Manufacturer’s part number and drawing number,
5. Designation,
6. National Stock Number (NSN), if available, and
7. Date of manufacture.

S2.14.1.2 Optoelectronics Module—At a minimum, the following information shall be provided on the label plate:
1. “OPTOELECTRONICS MODULE,”
2. Manufacturer’s name,
3. Manufacturer’s serial number,
4. Manufacturer’s part number,
5. Electrical and optical (if any) output (see S2.8.3),
6. National Stock Number (NSN), if available, and
7. Date of manufacture.

S2.14.2 Labeling—Labels shall be permanently and prominently marked.

S2.14.2.1 The legend “USE NO OIL FOR CALIBRATION” shall be marked on the sensor head housing.

S2.14.2.2 The legend “DO NOT LUBRICATE” shall be marked on the sensor head housing.

S2.14.2.3 A visible label, consisting of yellow lettering on a black background, shall be affixed to the outside of the optoelectronics module cover and shall contain the following:

NOTICE
UNTERMINATED OPTICAL CONNECTIONS MAY EMIT LASER RADIATION
DO NOT VIEW BEAM WITH OPTICAL INSTRUMENTS AND AVOID DIRECT EXPOSURE TO THE BEAM

S2.15 Packaging and Package Marking
S2.15.1 Packaging and package marking shall be in accordance with Section 15.

S2.16 Quality Assurance
S2.16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to effectively control the quality of the product being supplied, unless otherwise specified in the acquisition requirements (see S2.5.2).

S2.16.2 Warranty—Any special warranty requirements shall be specified in the acquisition requirements (see S2.5.2).

The following supplementary requirement, established for naval shipboard application, shall apply when specified in the contract or purchase order. When there is conflict between this specification and this supplementary requirement, this supplementary requirement shall take precedence.

S3. TRANSUCERS, SMART PRESSURE AND DIFFERENTIAL PRESSURE (ELECTRICAL)

S3.1 Scope
S3.1.1 This supplementary requirement covers the requirements for smart pressure and differential pressure transducers designed to meet the requirements for use onboard naval ships.

S3.1.2 The values stated in S1 units are to be regarded as the standard. Inch-pound units are provided for information only. Where information is to be specified, it shall be stated in S1 units.

S3.2 Referenced Documents
S3.2.1 ISO Standard:
6149-1 Connections for Fluid Power and General Use—Ports and Stud Ends with ISO 261 Threads and O-Ring Sealing—Part 1: Ports with O-Ring Seal in Truncated Housing

S3.2.2 NEMA Standard:
250 Enclosures for Electrical Equipment (1000 Volts Maximum)\textsuperscript{5}  

S3.2.3 **Military Standards:**  
MIL-S-901 Shock Tests, H.I. (High-Impact); Shipboard Machinery, Equipment and Systems, Requirements for\textsuperscript{6}  
MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment (Type I—Environmental and Type II—Internally Excited)\textsuperscript{6}  
MIL-STD-461 Electromagnetic Interference Characteristics of Subsystems and Equipment, Requirements for the Control of\textsuperscript{6}  

**S3.3 Terminology**  
S3.3.1 Terminology is consistent with that of Section 3 and the referenced documents.  

**S3.4 Classification**  
S3.4.1 **Designation**—For this specification, pressure transducer designations shall be assigned in accordance with S3.5.1 and listed in the following format:  

\textbf{Example:} F25XMS3-D-F-DC-2-10KD  

S3.4.2 **Types**—The following designators have been established for the various types of transducers:  
D—Pressure, differential  
P—Pressure (gage, absolute and sealed)  
V—Pressure, vacuum  
C—Pressure, compound  

S3.4.3 **Application**—The following application designations have been established for the corresponding process media:  
F—Freshwater, oil, condensate, steam, nitrogen and other inert gases  
S—Seawater  
G—Flue gas and ammonia  

S3.4.4 **Power Supply**—Transducers shall operate with dc input power. The designator shall be as follows:  
DC—Direct current supply  

S3.4.5 **Output**—The default dc electrical signal output of the transducer shall be designated by the following designators:  
2—4 mA  
3—1 to 5 V  
4—0.8 to 3.2 V  

S3.4.6 **Range**—The pressure range of the transducer shall be designated by two parts. The first part shall be the designator for the upper range value. The second part shall be the designator for the upper range unit of measure (see S3.4.6.1). The transducer pressure ranges shall be in accordance with Table S3.1.  

S3.4.6.1 **Units**—The units shall be designated by the corresponding letter designator and are limited to the following:  

\begin{tabular}{|c|c|c|c|}
\hline  
Letter & SI Units & Inch-Pound Units & \\
\hline  
V & KPaV—kiloPascals, vacuum & Hg—incches of mercury vacuum & \\
A & KPaA—kiloPascals, absolute & psia—pounds per square inch, absolute & \\
D & KPaD—kiloPascals, differential & psid—pounds per square inch, differential & \\
G & kPaG—kiloPascals, gauge & psg—pounds per square inch,gage & \\
S & kPaS—kiloPascals, sealed at 101.4 kPaA & psis—pounds per square inch, sealed at 14.7 psia & \\
W & kPaW—kiloPascals, water column, WC—and inches of water column & & \\
N & kPaWD—kiloPascals, water column, Differential & & \\
\hline  
\end{tabular}  

S3.5 **Ordering Information**  
S3.5.1 The purchaser shall provide the manufacturer with all of the pertinent application data in accordance with S3.5.2. If special application operating conditions exist that are not in the acquisition requirements, they shall also be described.  

S3.5.2 **Acquisition Requirements**—Acquisition documents shall specify the following:  
S3.5.2.1 Title, number, and date of this specification.  
S3.5.2.2 Part designation required (see S3.4.1).  
S3.5.2.3 National Stock Number (NSN), if available.  
S3.5.2.4 Mounting method, if other than specified herein (see S3.7.2).  
S3.5.2.5 Type of pressure connection, if other than specified herein (see S3.7.5).  
S3.5.2.6 Type of electrical connection, if other than specified herein (see S3.7.4).  
S3.5.2.7 Quantity of transducers required.  
S3.5.2.8 Quantity of handheld communicators required (see S3.7.8).  
S3.5.2.9 If deviation requests are not required when departing from material guidance (see S3.6).  
S3.5.2.10 When the first article inspection is required (see S3.12.3).  
S3.5.2.11 Special product marking requirements (see S3.13).  
S3.5.2.12 Special packaging or package marking requirements (see S3.14).

\end{table}
S3.5.2.13 When ISO 9001 quality assurance system is not required (see S3.16.1).
S3.5.2.14 Special warranty requirements (see S3.16.2).
S3.5.3 First-Article Tests—When first-article testing is required, the purchaser should provide specific guidance to offerors whether the item(s) should be a preproduction sample, a first-article sample, a first production item, a sample selected from the first production items, or a standard production item from the manufacturer’s current inventory. The number of items to be tested in accordance with S3.12.3 should be specified. The purchaser should also include specific instructions in acquisition documents regarding arrangements for tests, approval of first-article test results and time period for approval, and disposition of first articles. Invitations for bids should provide that the purchaser reserves the right to waive the requirement for samples for first-article testing to those manufacturers offering a product which has been previously acquired or tested by the purchaser; and that manufacturers offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior purchaser approval is presently appropriate for the pending contract. The manufacture of items before purchaser approval should be specified as the responsibility of the manufacturer.

S3.6 Materials
S3.6.1 Metals—Unless otherwise specified herein, all metals used in the construction of the transducer shall be corrosion-resistant or treated to provide corrosion resistance. Dissimilar metals shall not be used in contact with each other unless suitably finished to prevent electrolytic corrosion. The materials for the sensing element and wetted parts shall be selected for long-term compatibility (see S3.8.1) with the process medium (see S3.4.3).
S3.6.2 Flammable Materials—Materials used in the construction of the transducer shall in the end configuration be noncombustible or fire retardant in the most hazardous conditions of atmosphere, pressure, and temperature to be expected in the application. Fire retardance shall not be achieved by use of nonpermanent additives to the material.
S3.6.3 Fungus-Resistant Materials—Materials used in the construction of the sensor shall not support the growth of fungus.
S3.6.4 Solvents, Adhesives, and Cleaning Agents—When chemicals or cements are used in bonding of internal transducer components, no degradation shall result during in-service use.

S3.7 Physical Properties
S3.7.1 Enclosure—The transducer body and pressure cavity shall be environmentally sealed unless specified. The transducer enclosure shall be Type 4X in accordance with NEMA Standard 250.
S3.7.2 Transducer Mounting—The transducer shall be mounted on an integral coplanar flange/bracket, as shown in Fig. S3.1, for interface with the process medium. For Types P, V, and C transducers, the equalizing valve control handles shall be removed and equalizing valve ports shall be blanked.
S3.7.3 External Configuration—The transducer shall have an external configuration within the boundaries established by Figs. S3.1 and S3.2.

S3.7.4 Electrical Connection—A terminal block shall be provided in the transducer for connection of electrical conductors for power supply input, dc electrical signal output, and transducer case ground.
S3.7.5 Pressure Connections—The pressure connections that interface with shipboard systems shall be M12 × 1.5 (¾–20 UNF-2B) tube connection in accordance with ISO 6149-1. The traditional flange (see Fig. S3.2) provides these connections for differential pressure units and the flat adapter (see Fig. S3.3) provides these connections for pressure units. Differential units shall mount on the traditional flange and pressure units shall interface with the flat adapter.
S3.7.6 Digital Meter—The transducer shall have a direct reading digital meter to display pressure in pressure engineering units and in percent of analog range values. The meter shall display diagnostic messages for local troubleshooting. The meter shall be capable of being rotated 90° clockwise or counterclockwise within the transducer housing for meter reading flexibility.
S3.7.7 Communications Protocol—The transducer shall be microprocessor-based. The transducer shall be capable of digital communications with field devices using the frequency shift keying Highway Addressable Remote Transducer (HART) protocol supported by the HART Communication Foundation. Using the HART protocol, the transducer shall be capable of providing analog signal output (see 3.8.3) and digital communications over the same pair of wires.
S3.7.8 Handheld Communicator—A handheld communicator shall be provided when specified (see S3.5.2). The handheld communicator shall enable communication by an operator with the transducer using the HART protocol. The handheld communicator shall enable communicating with the transducer for configuration, test, and detailed setup of the transducer (see 3.8.5.2).
S3.7.9 Lubrication—The transducer shall operate without lubrication of moving parts after assembly.
S3.7.10 Damping—The use of a media for damping in transducers shall be cited on the equipment drawing.
S3.7.12 Weight—The weight of a transducer shall not exceed 2.7 kg (6 lb). The weight of a traditional flange/bracket shall not exceed 2.7 kg.

S3.8 Performance Requirements
S3.8.1 Service Life—The transducer shall be constructed for a life of 25 years of operation and shall meet the requirements specified herein when operated in the naval shipboard environment.
S3.8.2 Input Power—The transducer shall be designed to operate using 28 ± 4.5 Vdc power. The transducer shall operate with power supply variations as specified in S3.11.2.10 and S3.11.2.13.
S3.8.3 Output—The electrical signal output of the transducer shall be dc, directly proportional to the pressure or differential pressure input. The output shall be a true current source or true voltage source. The output type shall be selectable via a handheld communicator (see S3.7.8) or other device using the HART protocol. Selectable output types shall be 4 to 20 mA, 1 to 5 V, and 0.8 to 3.2 V.
S3.8.3.1 Current Output—When a 4- to 20-mA current output is selected, the requirements specified herein shall be met regardless of external load resistance variations over a range from 0 to 250 Ω. The 4-mA output shall correspond to the lower pressure or differential pressure range value and the 20-mA output shall correspond to the upper pressure or differential pressure range value for the transducer span programmed into the transducer (see S3.8.3.3).

S3.8.3.2 Voltage Output—When a voltage output is selected, the requirements specified herein shall be met for external load resistance exceeding 100 000 Ω. The 1- or 0.8-V output (output Type 3 or 4, respectively) shall correspond to the lower pressure or differential pressure range value for the transducer span programmed into the transducer (see 3.8.3.3). The 5- or 3.2-V output (output Type 3 or 4, respectively) shall correspond to the upper pressure or differential pressure range value for the transducer span programmed into the transducer (see 3.8.3.3).

S3.8.3.3 Floating (Live) Zero—The transducer shall be capable of assigning the low output value (4 mA, 1 V, or 0.8 V) to any pressure value within the programmed transducer span. The transducer shall be capable of assigning the high output value (20 mA, 5 V, or 3.2 V) to any pressure value within the programmed transducer span that is higher than the low output pressure value.

S3.8.4 Pressure Ports (Transducer Type D Only)—The transducer shall be capable of operation with either pressure port as the high-pressure port and the other as the low-pressure port. Selection of high- and low-pressure ports shall be programmable from a remote device using the HART protocol.

S3.8.5 Transducer Performance—Unless otherwise specified, performance tolerances are specified in percent of transducer output span for each settable span.

S3.8.5.1 Rangeability—Rangeability of the transducer shall be 100 to 1. Span values shall be settable anywhere within the range limits. Minimum span shall be no more than 1 % of the upper range value.

S3.8.5.2 Communications—The transducer shall be capable of communication with field devices using the HART protocol (see S3.7.8). The transducer shall be programmed such that

NOTE 2—The pressure port(s) shall be generally located as shown. Differential pressure transducer ports shall be located to match traditional flange/bracket configuration.

FIG. S3.1 Transducer External Configuration Boundary Limits
field device operators can perform configuration, test, and detailed setup of the transducer.

S3.8.5.2.1 Configuration—In the configuration mode, field device operators shall be capable of the adjustment of transducer operational parameters including, but not limited to, linear or square root output, damping, engineering unit selection, and assigning high and low pressure ports (differential transducers). The field device operator shall be capable of entering informational data for identification and physical description of the transducer. Informational data shall include tag, descriptor, and message fields for the transducer, date, flange type, flange material, drain/vent material, O-ring material, and remote seal information.

S3.8.5.2.2 Test—In the test mode, field device operators shall be capable of interrogation of the transducer when a problem has been detected. The field device operator shall be capable of being directed to give specific outputs for loop testing.

**FIG. S3.2 Traditional Flange/Bracket Configuration**

**NOTE 1—Dimension tolerance is ±1.25 mm (0.05 in.), unless otherwise specified.**
S3.8.5.2.3 Detailed Setup—The detailed setup mode is used during initial setup of the transducer and for maintenance of the digital electronics. Detailed setup shall include the setting of transducer zero and span values anywhere within available range limits, analog output selection, and transducer calibration. The field device operator shall be capable of selecting security features to prevent accidental or deliberate adjustment of analog output setpoints.

S3.8.5.3 Static Error Band—The transducer static error band shall not exceed \( \pm 0.25 \% \).

S3.8.5.4 Output—The output shall conform to S3.8.3 and the transducer performance shall be within the static error band specified in S3.8.5.3.

S3.8.5.5 Warm-Up Time—The transducer output shall attain a value within \( \pm 0.5 \% \) of the steady-state output with no overshoot in excess of 0.5%. Output shall reach this band within 2 s after the transducer is energized and shall remain in this band.

S3.8.5.6 Enclosure—The transducer shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures.

S3.8.5.7 Repeatability—Repeatability of transducer output shall be within 0.5%.

S3.8.5.8 Sensitivity Factor—The sensitivity factor shall not be less than 0.75 nor more than 1.25.

S3.8.5.9 Stability and Temperature—The transducer shall remain within the static error band specified in S3.8.5.3 throughout the stability and temperature test.

S3.8.5.10 Ripple—Transducer rms output ripple shall not exceed 0.15% of full-scale dc output.

S3.8.5.11 Steady-State Supply Voltage—Maximum difference between outputs at any voltage condition and the normal (28-Vdc) at the same input and test temperature (differential pressure shall be included for Type D) shall not exceed 0.5%.

S3.8.5.12 Pressure Rating and Common Mode Pressure (Transducer Type D Only)—Type D transducers shall have a pressure rating of 21 MPa (3000 lb/in.\(^2\)). During the common mode pressure test, transducer performance shall be within the range formed by extending the upper and lower static error band limits specified in S3.8.5.3 by a percentage equal to:

\[
\frac{1}{10} \left( \frac{\text{System pressure rating}}{\text{Differential pressure range}} \right)^{1/3}
\]

S3.8.5.13 Response—Transducer output shall conform to the following criteria, where all percentages are of transducer span:

1. The transducer output shall be within \( \pm 2 \% \) of the maximum ramp pressure within 0.01 s of the time that pressure is attained.
2. The transducer output shall exhibit no overshoot of maximum ramp pressure in excess of 2%.
3. The transducer output shall indicate the actual pressure to within \( \pm 1 \% \) in 0.175 s or less after attainment of maximum ramp pressure, and shall remain within this error band for the duration of applied steady-state pressure.
S3.8.5.14 Transient Supply Voltage—During the voltage transient test, the transducer output shall remain within ±0.5 % of the pretransient output.

S3.8.5.15 Power Interruption—During the power interruption test, transducer performance shall conform to S3.8.5.3.

S3.8.5.16 Overpressure—Calibration conducted after overpressure test shall have no values in excess of 1 % deviation from the pre-overpressure test reference measurement.

S3.8.5.17 Line Pressure (Transducer Type D Only)—After the line pressure test, transducer performance shall be within the static error band specified in S3.8.5.3.

S3.8.5.18 Pressure Cycling—Calibration conducted after completion of pressure cycling test shall have no values in excess of 1 % deviation from pretest reference measurement.

S3.8.5.19 Insulation Resistance—The insulation resistance of the transducer shall be not less than 10 MΩ.

S3.8.5.20 Vibration—Monitored transducer output during all phases of vibration test shall show no variation from steady-state output in excess of 2 %. There shall be no visible evidence of damage to the transducer as a result of the vibration test.

S3.8.5.21 Shock—The transducer shall operate during and after the shock test. After the shock test, the transducer output shall have no value in excess of 1 % deviation from the pre-shock test reference measurement. There shall be no visual evidence of damage to the transducer as a result of the shock test.

S3.8.5.22 Burst Pressure—The transducer shall withstand the burst pressure specified in S3.11.2.21 without showing any evidence of leakage.

S3.8.5.23 Short-Circuit Test—After the short-circuit test, the transducer shall exhibit no damage and shall conform to S3.8.5.3.

S3.8.5.24 Line Voltage Reversal Test—The transducer shall conform to S3.8.5.3 after the line voltage reversal test.

S3.8.5.25 Electromagnetic Interference (EMI)—The transducers shall meet the requirements of Table II of MIL-STD-461, except as modified as follows:

(1) CE101—The test signal shall be applied only to the ac power leads of the test sample.

(2) CE102—The test signal shall be applied only to the ac power leads of the test sample.

(3) CS114—Only Limit Curve #2 shall apply with the frequency range limited from 10 kHz to 30 MHz.

(4) RE101—Only the limit curve for 50 cm shall apply.

(5) RS103—The frequency range shall be limited from 10 kHz to 18 GHz with an electric field strength test level of 10 V/m.

S3.9 Workmanship, Finish, and Appearance

S3.9.1 Transducer Cleaning—The manufacturer shall ensure that pressure transducers shall be free of all loose scale, rust, grit, filings and other foreign substances and free of mercury, oil, grease, or other organic materials. Transducers for all applications shall be freshwater or clean gas calibrated, cleaned, and pressure connections capped.

S3.10 Number of Tests and Retests

S3.10.1 Test Specimen—(see 10.1).

S3.11 Test Methods

S3.11.1 Test Conditions—Except where the following factors are the variables, the tests specified in S3.11.2 shall be conducted with the equipment under the following operating environmental conditions:

S3.11.1.1 Ambient temperature shall be 23 ± 2°C.

S3.11.1.2 Relative humidity shall be ambient.

S3.11.1.3 Range Setting—The transducer has a rangeability from 100 to 1 (S3.8.5.1). All tests, excluding static error band and repeatability (S3.11.2.6), shall be conducted with the transducer set at approximately the mid range. Static error band and repeatability shall be accomplished at 3 ranges (low, medium, and high) within the capability of the transducer under test.

S3.11.2 Tests—Except for the warm-up time test (see S3.11.2.4), the transducer and all associated test equipment shall be energized for a period of time sufficient to ensure complete warm-up.

S3.11.2.1 Reference Measurement—A reference measurement consisting of a one-trial calibration with at least five equally spaced intervals over the entire transducer range both upscale and downscale shall be conducted when specified in the individual test.

S3.11.2.2 Communications—The test shall be conducted with a handheld communicator using the HART protocol. Configuration, test, and detailed setup of the transducer shall be performed. In the test mode, transducer problems shall be simulated to verify test mode functions. Performance shall conform to S3.8.3, S3.8.4, S3.8.5.1, and S3.8.5.2. All handheld communicator functions shall be verified.

S3.11.2.3 Output—Three reference measurements shall be made in accordance with S3.11.2.1. Each reference measurement shall use a different set of low- and high-output values (see S3.8.3.3). Performance shall conform to the requirements of S3.8.5.4.

S3.11.2.4 Warm-Up Time—The test shall be conducted to determine the elapsed time between the application of line power to the transducer and the point at which the transducer output reaches the conditions specified in S3.8.5.5.

S3.11.2.4.1 Test Conditions—The transducer shall be subjected to the ambient temperature of the testing location, while deenergized, for not less than 2 h. Recording equipment and other auxiliary equipment shall be energized to ensure complete warm-up. An input pressure (differential pressure for Type D) of 80 ± 5 % of the transducer upper range limit shall be applied to the transducer and maintained constant during this test. Performance shall conform to S3.8.5.

S3.11.2.5 Enclosure—The enclosure shall be subjected to the tests in NEMA Standard 250 for Type 4X enclosures. Performance shall conform to S3.8.5.6.

S3.11.2.6 Static Error Band and Repeatability—The transducer shall first be flexed over its full pressure range by slowly increasing and decreasing the applied pressure for six continuous cycles. The calibration measurement shall be made at a minimum of five equally spaced intervals over the entire range (both upscale and downscale). Precaution shall be taken to avoid overshoot. This calibration procedure shall be applied three successive times to determine repeatability. Static error...
band of all calibrations shall meet the requirements of S3.8.5.3. Repeatability shall meet the requirements of S3.8.5.7.

S3.11.2.7 Sensitivity Factor—The sensitivity factor shall be determined as follows: Provide a pressure (differential pressure for transducer Type D) to the transducer of 80 ± 5 % of transducer upper range limit. Record the input pressure (differential pressure) and corresponding electrical output. Increase the pressure (differential pressure) by an amount not exceeding 1 % of upper range limit. Record both the new pressure (differential pressure) and corresponding new electrical output. Calculate the change in both applied pressure (differential pressure) and electrical output as a percentage of transducer range. Determine the ratio of electrical output percentage change to applied pressure (differential pressure) percent change. Repeat this procedure for a pressure (differential pressure) decrease not exceeding 1 % of upper range limit. Performance shall conform to the requirements of S3.8.5.8.

S3.11.2.8 Stability and Temperature—The transducer shall be operated at an input pressure (differential pressure for transducer Type D) of 80 ± 5 % of transducer upper range limit for a period of ten days. Starting ambient temperature shall be 25 ± 2°C. At the end of three days, the ambient temperature shall be changed to 0 ± 2°C. At the end of five days, the ambient temperature shall be changed to 65 ± 2°C. At the end of seven days, the ambient temperature shall be returned to 25 ± 2°C. Performance shall conform to the requirements of S3.8.5.9.

S3.11.2.9 Ripple—Transducer output rms ripple shall be determined at an input pressure (differential pressure for transducer Type D) of 80 ± 5 % of transducer upper range limit. Performance shall conform to the requirements of S3.8.5.10.

S3.11.2.10 Steady-State Supply Voltage—The transducer shall be operated at normal, maximum, and minimum steady-state voltages (dc). Performance shall conform to S3.8.5.11.

S3.11.2.11 Common Mode Pressure (Transducer Type D Only)—The rated pressure of the transducer shall be applied simultaneously to both pressure ports. The pressure at the assigned low-pressure port shall then be decreased in pressure increments specified in S3.11.2.1 to the specified transducer range and then increased in similar increments to the transducer-rated pressure. Performance shall conform to S3.8.4 and S3.8.5.12. The test shall be conducted once with each pressure port as the assigned low-pressure port.

S3.11.2.12 Response—A pressure (differential pressure for Type D) ramp consisting of a pressure (differential pressure for Type D) rise of at least 40 % of transducer upper range limit occurring at the rate of not less than 400 % per second shall be applied to the transducer. The maximum ramp pressure shall be maintained for at least 0.50 s and shall not vary by more than ±2 % of the transducer upper range limit. Performance shall conform to S3.8.5.13.

S3.11.2.13 Transient Supply Voltage—Tests shall be conducted with a pressure (differential pressure for transducer Type D) input signal equal to 80 ± 5 % of the transducer upper range limit. With the transducer operating at the upper and lower limits of steady-state dc voltage, the dc-powered transducer shall have a transient voltage of no more than ±2 V, respectively, recovering to the steady-state band in 2 s, superimposed. Performance shall conform to the requirements of S3.8.5.14.

S3.11.2.14 Power Interruption—An input pressure (differential pressure for transducer Type D) of 80 ± 5 % of transducer upper range limit shall be applied to the transducer and maintained constant during the test. With the transducer operating within the steady-state voltage tolerances, the external power supply shall be interrupted for an interval of 3 to 4 s. The power supply shall then be reestablished to within steady-state tolerances. The transducer shall be operated at steady-state power for 1 min. The power supply shall then be interrupted for an interval of 30 s. This cycle shall be repeated three times. Performance shall conform to the requirements of S3.8.5.15.

S3.11.2.15 Overpressure—Before the overpressure test, a reference measurement in accordance with S3.11.2.1 shall be made. The transducer shall successfully withstand pressure (differential pressure for transducer Type D) equal to 200 % of its upper range limit with a maximum pressure of 85 MPa (12 000 lb/in.²) for a period of ½ h. At the end of this period, transducers shall be immediately subjected to a pressure equal to 7 kPa (1 lb/in.²) or 10 % of upper range limit, whichever is less, below atmospheric for an additional period of ½ h. Within 10 min after release of this pressure, a reference measurement (see S3.11.2.1) shall be made for comparison. Performance shall conform to S3.8.5.16. For Type D only, if the line pressure rating exceeds 200 % of the maximum differential pressure range, the overpressure test shall be omitted and 0.5 % deviation shall be applied to the line pressure test (see S3.11.2.16).

S3.11.2.16 Line Pressure (for Transducer Type D Only)—The transducer shall successfully withstand the pressure rating, when applied to one pressure port with the other pressure port vented to the atmosphere for a period of 10 min. The preceding shall be repeated with the pressure applied to the opposite pressure port of the transducer. After each test, a reference measurement in accordance with S3.11.2.1 shall be made. Performance shall conform to S3.8.5.17.

S3.11.2.17 Pressure Cycling—Before performing the pressure cycling test, a reference measurement shall be made (see S3.11.2.1). The test shall be conducted on a suitable system by applying a periodic pressure change of not more than 20 % to not less than 80 % of upper range limit for a total of 260 000 cycles. The rate of cycling shall be within the range from 0.25 to 2 Hz. The transducer shall be energized throughout the test. After completion of the pressure cycling test, a reference measurement shall be made for comparison (see S3.11.2.1). Performance shall conform to S3.8.5.18.

S3.11.2.18 Insulation Resistance—The insulation resistance of the transducer shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The relative humidity shall be 50 ± 10 %. The insulation resistance measurement shall be made immediately after a 2-min period of uninterrupted test voltage application. However, if the indication of insulation resistance
meets the specified limit (see S3.8.5.19) and is steady or increasing, the test may be terminated before the end of the two minute period.

S3.11.2.19 Vibration—The transducer shall be tested in accordance with Type I (environmental) vibration of MIL-STD-167-1. The following exceptions apply: the upper frequency shall be 175 Hz, the amplitude of vibration shall be in accordance with Table S3.2 for the variable frequency portion, and the vibration level shall be maintained for 2 min at each integral value of frequency. If no resonance frequencies are observed, the 2-h endurance test shall be conducted at 175 Hz. During the vibration test, a fluid pressure of 80 ± 5 % of the transducer upper range limit shall be applied to the transducer. Transducer output during the test shall be monitored. Performance shall conform to S3.8.5.20.

S3.11.2.20 Shock—The shock tests shall be conducted in accordance with Grade A, Class 1, Type C using bulkhead mounting fixture 4-A of MIL-S-901. During the test, a fluid pressure (differential pressure for transducer Type D) of 80 ± 5 % of the transducer upper range limit shall be applied to the transducer. The transducer output during the test shall be unshorted. The transducer shall be energized for 5 min. Immediately following shall be connected together with no load resistance. The electrical output terminals of the transducer shall first be approved by the purchaser. In Table S3.3 in the order listed. Any deviation in the test order shall be as specified in S3.8.5.23. Failure of any pressure transducer to meet the requirements of this specifica-
tion shall conform to S3.8.5.21.

S3.11.2.21 Burst Pressure—The transducer shall be subjected to a liquid pressure equal to 300 % of the upper range limit with a maximum pressure of 105 MPa (15 000 lb/in.²) applied to the transducer (simultaneously to both sides for transducer Type D) for a period of 10 min. The transducer shall conform to the requirements of S3.8.5.22. No performance test shall be required after the burst pressure test. A reference measurement (see S3.11.2.1) shall be recorded for information purposes.

S3.11.2.22 Short Circuit—An input pressure (differential pressure for transducer Type D) of 80 ± 5 % of transducer upper range limit shall be applied to the transducer and maintained constant during the test. The transducer shall be de-energized. The electrical output terminals of the transducer shall be connected together with no load resistance. The transducer shall be energized for 5 min. Immediately following the 5-min period, the output terminals shall be unshorted. The transducer shall conform to the requirements of S3.8.5.23.

S3.11.2.23 Line Voltage Reversal—An input pressure (differential pressure for transducer Type D) of 80 ± 5 % of transducer upper range limit shall be applied to the transducer and maintained constant during the test. The +28-Vdc conductor from the power supply shall be connected to the negative terminal on the transducer terminal board. The –28-Vdc conductor from the power supply shall be connected to the positive terminal on the transducer terminal board. The transducer shall be energized for a period of 10 min and then disconnected. The power shall then be correctly connected (positive conductor to positive terminal and negative conductor to negative terminal). A reference measurement shall be made (see S3.12.2.1). The transducer shall conform to the requirements of S3.8.5.24.

S3.11.2.24 EMI Tests—The EMI tests shall be in accordance with the test methods specified in MIL-STD-461, with the modifications as specified in S3.8.5.25. Performance shall be as specified in S3.8.5.25.

S3.12 Inspection

S3.12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

S3.12.1.1 First-article tests (see S3.12.3).
S3.12.1.2 Conformance tests (see S3.12.4).
S3.12.2 First-Article Tests—First-article tests shall be performed before production. First-article tests shall be performed on samples that have been produced with equipment and procedures normally used in production. First-article tests shall consist of the tests specified in Table S3.3. Failure of any pressure transducer to meet the requirements of this specification shall be cause for rejection.

S3.12.2.1 Order of First-Article Tests—With the exception of the electromagnetic interference emission and susceptibility test which may be conducted on separate transducers, the test specimens (transducers) shall be subjected to the tests specified in Table S3.3 in the order listed. Any deviation in the test order shall first be approved by the purchaser.

S3.12.3 Conformance Tests—Each pressure transducer in each lot offered for delivery shall be subjected to the tests listed

in Table S3.4 and shall be conducted in the order listed. Failure of any pressure transducer to meet the requirements of this specification shall be cause for rejection.

S3.12.4 General Examination—Each transducer shall be given a thorough examination to determine conformance to the requirements of this specification with respect to material, finish, workmanship, construction, assembly, dimensions, weight, and marking of identification. Examination shall be limited to the examinations that may be performed without disassembling the units. The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with applicable approved industry standards.

S3.13 Certification
S3.13.1 The purchase order or contract should specify whether the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. The purchase order or contract should specify when a report of the test results shall be furnished. Otherwise, the purchase order or contract should specify that all test data remain on file for three years at the manufacturer’s facility for review by the purchaser upon request.

S3.14 Product Marking
S3.14.1 Label Plates—A label plate with engraved or stamped markings shall be permanently affixed to the transducer. At a minimum, it shall contain the following:
S3.14.1.1 PRESSURE TRANSDUCER" or “DIFFERENTIAL PRESSURE TRANSDUCER;”
S3.14.1.2 Manufacturer’s name,
S3.14.1.3 National Stock Number (NSN), if available,
S3.14.1.4 Date of manufacture,
S3.14.1.5 Designation, and
S3.14.1.6 Pressure rating for Type D transducers.
S3.14.2 Transducers for use with Application F shall have “USE NO OIL FOR CALIBRATION” prominently marked on the body.
S3.14.3 The legend “DO NOT LUBRICATE” shall be prominently marked on the body.

S3.15 Packaging and Package Marking
S3.15.1 Packaging and package marking shall be in accordance with Section 15.

S3.16 Quality Assurance
S3.16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see S3.5.2).
S3.16.2 Warranty—Any special warranty requirements shall be specified in the acquisition requirements (see S3.5.2).

Standard Specification for Switch, Position Proximity (Noncontact) or Limit (Mechanical Contact), Fiber-Optic

1. Scope

1.1 This specification covers the requirements for fiber-optic position switches (proximity and limit). This specification does not include switches that transfer an optical signal from one path to another by an external force or energy applied to the switch.

1.2 The values stated in SI units are to regarded as the standard. The values given in parentheses are for information only. Where information is to be specified, it shall be stated in SI units.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.4 Special requirements for naval shipboard applications are included in the Supplement.

2. Referenced Documents

2.1 ASTM Standards:
D 3951 Practice for Commercial Packaging

2.2 ISO Standards:
ISO 9001 Quality System—Model for Quality Assurance in Design/Development, Production, Installation, and Servicing

3. Terminology

3.1 Definitions:
3.1.1 closed switch—the light path is complete; signal from transmitter to receiver is complete.

3.1.2 closed switch with positive alarm—the light path is complete. Signal level indicates that the end faces of the sensing element are dirty and require maintenance for continued proper operation.

3.1.3 fiber-optic position switch—a device that converts measured position, via changes in fiber-optic properties, to an output that is a function of the applied measurand. The fiber-optic position switch normally consists of a sensor head, optoelectronics module, and connectorized fiber-optic cable.

3.1.4 limit switch—a switch that senses a change in position via mechanical contact.

3.1.5 open switch—the light path is blocked; signal from transmitter to receiver is not complete.

3.1.6 optical transmittance change—the change in optical power level introduced by an environmental, mechanical, or other induced stress.

3.1.7 optoelectronics module—unit of the fiber-optic position switch that contains the optical transmitter and receiver, and signal conditioning electronics, necessary to convert the sensed position to the specified output signal. The optoelectronics module may be an expansion card for a microprocessor-based system, or a stand-alone unit.

3.1.8 proximity switch—a switch that senses a change in position via noncontact means.

3.1.9 sensor head—unit of the fiber-optic position switch that detects position via changes in optical properties. The optoelectronics module interrogates the sensor head to determine the position of the measurand. An optical signal is transmitted from the optoelectronics module to the sensor head. The optical path is either complete or blocked, depending on the status of the item being measured, giving an indication of the position or status of the item back to the optoelectronics module.

3.1.10 steady-state supply voltage—an input voltage that does not deviate from a specified nominal tolerance (ex: ±5 %).

3.1.11 tether valve limit switch—a limit switch used to detect valve position via a tether line connected to the valve handle.

3.1.12 transient supply voltage—a voltage superimposed on the steady-state supply voltage that is greater than the specified steady-state tolerance and has a very rapid rise and fall.

4. Classification

4.1 Designation—Most switch manufacturers use designations, systematic numbering or identifying codes. Once understood, these designations could aid the purchaser in quickly identifying the switch type, electrical power ratings, and other characteristics.
4.2 Design—Fiber-optic position switches typically consist of an assembly with three major components: optical sensor head, fiber-optic cables, and optoelectronics module. The optoelectronics module shall be interchangeable between any of the sensor types.

4.3 Types—The following are common types of fiber-optic position switches:

   - Proximity
   - Limit, pin actuated
   - Limit, lever actuated
   - Limit, lever and roller
   - Limit, tether valve

4.3.1 Fiber-Optic Proximity Switches—The fiber-optic proximity switch sensor head receives the light beam from the light source in the optoelectronics module via a fiber-optic cable. The sensor head emits the light beam to detect an object in a specific location. The sensor head also receives the light beam reflection from the object, typically via a wide angle receiving lens, and is detected by the light beam receiving device in the optoelectronics module. When the object moves into the sensing site, the light beam is reflected into the receiving lens completing the fiber-optic light path. It is important to consider contrasting light levels between reflections from background objects when no object to be detected is present and reflections from the object to be detected, when selecting a fiber-optic proximity switch.

4.3.2 Fiber-Optic Limit Switches—The fiber-optic limit switch sensor head houses the mechanical contact device that senses the position of the object to be detected. The mechanical contact device is typically a pin or plunger, lever, roller, lever and roller, or tether valve. The fiber-optic limit switch sensor head receives the light beam from the light source in the optoelectronics module via a fiber-optic cable. The same fiber-optic cable allows completion of the light path to a fiber-optic receiver in the optoelectronics module. Dependent upon the configuration of the switch, the mechanical contact device either completes or breaks the light path upon detection of the object.

5. Ordering Information

5.1 The purchaser should provide the manufacturer with all of the pertinent application data. Recommended data is shown in 5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they should also be described.

5.2 Acquisition Requirements—Acquisition documents should specify the following:

   - Title, number, and date of this specification,
   - Manufacturer’s part number,
   - Switch type required (see 4.3),
   - Unique or special enclosure requirements (see 7.1),
   - Type of optoelectronics module (see 7.2). If control enclosure or console mounted, specify requirements,
   - Length of fiber-optic cable required,
   - Type of electrical connection (see 7.4),
   - When the electrical connection mating plug is not to be provided (see 7.4),
   - System operating characteristics,
   - Materials,
   - Environmental requirements,
   - Quantity of switches required,
   - Size and weight restrictions (see 7.5),
   - Critical service life requirements (see 8.1),
   - Performance requirements (see 8.2),
   - Special surface finish requirements (see 9.1),
   - Special workmanship requirements (see 9.2),
   - When certification is required (see 13),
   - Special marking requirements (see 14),
   - Special packaging or package marking requirements (see 15),
   - When ISO 9001 quality assurance system is not required (see 16.1), and
   - Special warranty requirements (see 16.1).

6. Materials and Manufacture

6.1 Position Switches—Materials for the fiber-optic position switches shall be corrosion resistant and noncombustible or fire retardant.

7. Physical Properties

7.1 Enclosure—If case sealing is required, the mechanism, materials, and process shall be described. The same should apply to the electrical connector. Resistance to cleaning solvents should likewise be stated. Unique or special enclosure requirements shall be specified in the acquisition requirements (see 5.2).

7.2 Optoelectronics Module—The optoelectronics module shall contain the optical and signal conditioner devices necessary to convert the sensor head output to the specified electrical output. Optoelectronics modules shall be designed in consideration of their mounting method (type): bulkhead mounted, control enclosure mounted, or console mounted (microprocessor expansion card).

7.3 External Configuration—The outline drawing shall show the configuration with dimensions in SI units (inch-pound units) if they are not specified. The outline drawing shall include limiting dimensions for electrical and fiber-optic connections if they are not specified. The outline drawing shall indicate the mounting method with hole size, center location, and other pertinent dimensions. Where threaded holes are used, thread specifications shall be provided.

7.4 Electrical Connection—An electrical interface connector receptacle and mating plug shall be provided with each optoelectronics module of the position switch unless otherwise specified in the acquisition requirements (see 5.2). Other possible electrical interface connections include pigtails and terminal boards.

7.5 Size and Weight—The purchaser may have intended applications in which size and weight are limited. Size and weight restrictions shall be specified in the acquisition requirements (see 5.2).

8. Performance Requirements

8.1 Service Life—The purchaser may have a minimum specified service life requirement that may be critical. Critical service life requirements shall be specified in the acquisition requirements (see 5.2).
8.2 Switch Performance—Critical performance requirements shall be specified in the acquisition requirements (see 5.2). The following performance characteristics and environmental exposures may or may not be important to each purchaser’s intended application.

(a) Warm-up time,
(b) Steady-state supply voltage and frequency (ac),
(c) Steady-state supply voltage (dc),
(d) Response time,
(e) Transient supply voltage and frequency (ac),
(f) Transient supply voltage (dc),
(g) Change in optical transmittance,
(h) Dynamic range,
(i) Ambient light susceptibility,
(j) Temperature,
(k) Humidity,
(l) Salt spray,
(m) Insulation resistance,
(n) Power interruption,
(o) Short circuit,
(p) Line voltage reversal (dc powered),
(q) Output,
(r) Mechanical life,
(s) Enclosure,
(t) Vibration,
(u) Shock,
(v) Electromagnetic interference (EMI), and
(w) Power system harmonic distortion.

9. Workmanship, Finish and Appearance

9.1 Finish and Appearance—Any special surface finish and appearance requirements shall be specified in the acquisition requirements (see 5.2).

9.2 Workmanship—Any special workmanship requirements shall be specified in the acquisition requirements (see 5.2).

10. Number of Tests and Retests

10.1 The number of test specimens to be subjected to first-article and conformance tests shall be specified and should depend on the fiber-optic position switch design. As guidance, for each switch covered by a separate and distinct design, a test specimen for each design should require testing. In instances in which a singular design series may cover multiple switch configurations, a minimum of three test specimens should be tested, provided the electrical, optical, and mechanical similarities are approved by the purchaser. It is recommended that one unit be tested for each switch configuration regardless of design similarity.

11. Inspection

11.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

(a) First-article tests (see 11.2)
(b) Conformance tests (see 11.3)

11.2 First-Article Tests—First-article test requirements shall be specified, where applicable. First-article test methods should be identified for each design and performance characteristic specified.

11.3 Conformance Tests—Conformance testing is accomplished when first-article tests were satisfied by a previous acquisition or the product has demonstrated reliability in similar applications. Conformance tests are usually less intensive than first-article tests, often verifying that samples of a production lot meet a few critical performance requirements.

12. Test Data

12.1 Test Data—Test data shall remain on file at the manufacturer’s facility for review by the purchaser upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years or a period of time acceptable to the purchaser and manufacturer.

13. Certification

13.1 When specified in the acquisition requirements (see 5.2), the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met.

14. Product Marking

14.1 Special purchaser specified product marking shall be listed in the acquisition requirements (see 5.2). The minimum data to be clearly marked on each switch shall include the following:

14.1.1 Sensor Head:

(a) “FIBER-OPTIC POSITIONS SWITCH—SENSOR HEAD,”
(b) Manufacturer’s name,
(c) Manufacturer’s serial number or lot number, and
(d) Manufacturer’s part number.

14.1.2 Optoelectronics Module:

(a) “FIBER-OPTIC POSITIONS SWITCH—OPTOELECTRONICS MODULE”
(b) Manufacturer’s name,
(c) Manufacturer’s serial number or lot number,
(d) Manufacturer’s part number, and
(e) Excitation voltage.

15. Packaging and Package Marking

15.1 Packaging of Product for Delivery—Product should be packaged and marked for shipment in accordance with Practice D 3951.

15.2 Special packaging or package marking requirements for shipment or storage shall be identified in the acquisition requirements (see 5.2).

16. Quality Assurance

16.1 Quality System—A quality assurance system in accordance with ISO 9001 shall be maintained to control the quality of the product being supplied effectively, unless otherwise specified in the acquisition requirements (see 5.2).

16.2 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:

(a) All materials used to produce a unit and
(b) Workmanship to produce the unit.

Special warranty requirements shall be specified in the acquisition requirements (see 5.2).
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard F25(FOSW)M-99 and this supplement, the requirements of this supplement shall take precedence for equipment acquired by this supplement. This document supersedes MIL-S-24798, Switch, Position, Proximity (Non-Contact) or Limit (Mechanical Contact), Fiber Optic, for new ship construction.

S1. SWITCH, POSITION, PROXIMITY (NONCONTACT) OR LIMIT (MECHANICAL CONTACT), FIBER-OPTIC

S1.1 Scope
S1.1.1 This specification supplement covers the requirements for fiber-optic position switches (proximity and limit) designed to meet the requirements for use onboard naval ships. This specification does not include switches that transfer an optical signal from one path to another by an external force or energy applied to the switch.
S1.1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are provided for information only.

S1.2 Referenced Documents
S1.2.1 ASTM Standards:
- D 542 Test Methods for Index of Refraction of Transparent Organic Plastics
- D 570 Test Method for Water Absorption of Plastics
S1.2.2 EIA Standards:
- 455-20 FOTP-20 Measurement of Change in Optical Transmittance
- 455-22 FOTP-22 Ambient Light Susceptibility of Fiber Optic Components
- 455-34 FOTP-34 Interconnection Device Insertion Loss Test
S1.2.3 NEMA Standards:
- 250 Enclosures for Electrical Equipment (1000 Volts Maximum)
S1.2.4 Military Standards
- MIL-C-83522 Connectors, Fiber Optic, Single Terminus, General Specification for
- MIL-C-83522/16 Connector, Fiber Optic, Single Terminus, Plug, Adapter Style, 2.5 Millimeter Bayonet Coupling, Epoxy
- MIL-C-83522/17 Connector, Fiber Optic, Single Terminus, Adapter, 2.5 Millimeter Bayonet Coupling, Bulkhead Panel Mount

S1.3 Terminology
S1.3.1 Terminology is consistent with that of Section 3 and the referenced documents.

S1.4 Designation
S1.4.1 Designation—For this specification, fiber-optic position switch designations shall be assigned as specified in S1.5.2 and listed in the format below:

Example: F25(FOSW)M-1-B-DC

<table>
<thead>
<tr>
<th>Specification</th>
<th>Type</th>
<th>Optoelectronics Module</th>
<th>Power Supply</th>
</tr>
</thead>
<tbody>
<tr>
<td>F25(FOSW)M-99</td>
<td>1</td>
<td>B</td>
<td>DC</td>
</tr>
<tr>
<td>S1.4.2</td>
<td></td>
<td>S1.4.3</td>
<td>S1.4.4</td>
</tr>
</tbody>
</table>

S1.4.2 Type—The following designators have been established for the various types of fiber-optic position switches:
1—Proximity position switch sensor head,
2—Pin-actuated limit position switch sensor head,
3—Lever-actuated limit position switch sensor head,
4—Lever and roller limit position switch sensor head,
5—Tether valve limit position switch sensor head,
6—Special (see S1.5.2).

S1.4.3 Optoelectronics Module—The optoelectronics module shall be designated as follows:
A—Bulkhead mounted,
B—Control enclosure mounted, and
C—Console mounted (microprocessor or programmable logic controller expansion card).

S1.4.4 Electrical Power Supply—The electrical interface wiring shall be determined by the power supply as follows:
S1.5 Ordering Information
S1.5.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with S1.5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S1.5.2 Acquisition Requirements—Acquisition documents shall specify the following:
(a) Title, number, and date of this specification;
(b) Part designation (see S1.4.1);
(c) Special type position switch (see S1.4.2) description and unique requirements;
(d) National Stock Number (NSN) if available;
(e) Sensor head mounting requirements (see S1.7.2);
(f) Requirements when Type B or Type C optoelectronics module is specified (see S1.7.3.2 and S1.7.3.3);
(g) Optoelectronics module mounting method if other than specified herein (see S1.7.3);
(h) Type of fiber-optic connectors, receptacles, and bulkhead adapters, if other than specified herein (see S1.7.4);
(i) Fiber-optic cable length required (see S1.7.6);
(j) Critical dimensions of the switch (see S1.7.13);
(k) Quantity of switches required;
(l) When first-article tests are required (see S1.12.2);
(m) Special marking requirements (see S1.14);
(n) Special packaging or package marking requirements (see S1.15); and
(o) Special warranty requirements (see S1.16.1).

S1.5.3 First-Article Tests—The purchaser should include specific instructions in acquisition documents regarding arrangements for tests, approval of first-article test results and time period for approval, and disposition of first articles. Invitations for bids should provide that the purchaser reserves the right to waive the requirement for samples for first-article inspection to those manufacturers offering a product which has been previously acquired or tested by the purchaser, and that manufacturers offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior purchaser approval is presently appropriate for the pending contract. The manufacture of items before purchaser approval should be specified as the responsibility of the manufacturer.

S1.6 Materials
S1.6.1 Metals—Unless otherwise specified herein, all metals used in the construction of the proximity or limit position switch shall be corrosion resistant. Dissimilar metals shall not be used in contact with each other unless suitably finished to prevent electrolytic corrosion.

S1.6.2 Flammable Materials—Materials used in the construction of the proximity or limit position switch shall be noncombustible or fire retardant in the most hazardous conditions of atmosphere, pressure, and temperature to be expected in the application. Fire-retardant additives may be used provided they do not adversely affect the specified performance requirements of the basic materials. Fire retardance shall not be achieved by use of nonpermanent additives to the basic material.

S1.6.3 Fungus-Resistant Materials—Materials used in construction of the switch sensor head and optoelectronics module shall not support the growth of fungus.

S1.6.4 Solvents, Adhesives, and Cleaning Agents—When chemicals or cements are used in bonding of internal proximity or limit position switch components, no degradation shall result during in-service use.

S1.6.5 Refractive Index Matching Gels, Fluids, or Compounds—Refractive index matching gels, fluids, or compounds shall not produce toxic, corrosive, or explosive byproducts. The material is subject to a toxicological data and formulations review and inspection, for safety of material, by the purchaser. The index matching material shall be either silicone or aliphatic hydrocarbon material and shall be clear and transparent. The index matching material shall have an index of refraction of 1.46 ± 0.01 as tested in accordance with Test Methods D 542, when exposed to operating temperature extremes between −28°C and +85°C. The index matching material shall not flow at elevated temperatures. The index matching material shall remain clear and transparent when tested for water absorption in accordance with Test Method D 570. The index matching material shall have a shelf life not less than 36 months at 25°C ± 5°C. The 36-month period commences on the date of adhesive manufacture.

S1.7 Physical Properties
S1.7.1 Design and Construction—The switch shall consist of an assembly with three major components: optical sensor head, fiber-optic cable, and optoelectronics module. The optoelectronics module shall be interchangeable between any of the sensor head types (see S1.4.2).

S1.7.2 Sensor Head—The sensor head shall meet the requirements specified herein. Sensor head mounting requirements shall be as required for the switch application and specified in the acquisition requirements (see S1.5.2). It is recommended that the sensor head be installed such that sufficient clearance is provided for repair and maintenance of the unit.

S1.7.3 Optoelectronics Module—The optoelectronics module shall contain the optical and signal conditioner devices necessary to convert the sensor head output to the specified electrical output. The module shall be bulkhead mounted, control enclosure mounted, or console mounted as specified in the acquisition requirements (see S1.5.2).

S1.7.3.1 Bulkhead Mounted (Type A)—Bulkhead-mounted optoelectronics modules shall be housed in a junction box. The junction box maximum dimensions shall be 280-mm L by 205-mm W by 130-mm D (11-in. L by 8-in. W by 5-in. D). The junction box material shall be brass. The junction box shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures. The optoelectronics module shall be subjected to all first-article tests as specified (see S1.12.1) before mounting in the junction box.

S1.7.3.2 Control Enclosure Mounted (Type B)—Control enclosure-mounted optoelectronics modules are intended for use within an environmental protective enclosure as part of a
motor controller or other system. The optoelectronics module shall be mounted in an enclosure as specified in the acquisition requirements (see S1.5.2). The optoelectronics module shall be subjected to all first-article tests as specified (see S1.12.1) before mounting in the enclosure.

S1.7.3.3 Console Mounted (Type C)—Console-mounted (microprocessor or programmable logic controller (PLC) expansion card) optoelectronics modules are intended for use as a plug-in card for a console control system. The optoelectronics module shall be packaged in a console-mounted circuit card as specified in the acquisition requirements (see S1.5.2). The size, weight, pinout configuration, and number of channels shall be as specified in the acquisition requirements (see S1.5.2).

S1.7.4 Fiber-Optic Cable—A fiber-optic cable shall be used to connect sensor head to the optoelectronics module. There shall be no less than two times the number of fibers needed for operation of the switch in the cable. Penetration of the fiber-optic cable into the sensor head and the optoelectronics module shall be watertight. The required length of cable shall be as specified in acquisition requirements (see S1.5.2).

S1.7.5 Optical Fiber—All optical fiber used in the construction of the fiber-optic switch shall be in accordance with MIL-PRF-49291.

S1.7.6 Fiber-Optic Connectors, Receptacles, and Bulkhead Adapters—All fiber-optic connectors, receptacles, and bulkhead adapters shall be in accordance with MIL-C-83522 and MIL-C-83522/16, 17, and 18, respectively, or equal. Connectors shall be assembled at both ends of the fiber-optic cable between the sensor head and the optoelectronics module.

S1.7.7 Local Status Indication—The switch optoelectronics module shall have three indicator light-emitting diodes (LEDs): (1) a green LED that indicates the switch is closed when illuminated, (2) a red LED that indicates the switch is open when illuminated, and (3) a yellow LED that indicates a switch is closed with alarm level condition when illuminated. The LEDs shall be located on either the top or front of the module as it would be mounted during usage. The LEDs shall be visible in fluorescent room lighting. One LED and only one LED shall be lit at all times when the optoelectronics unit is energized.

S1.7.8 Low-Intensity Alarm Set Point Adjustment—The switch shall provide an indication of a degradation in the intensity of the transmitted optical signal via an alarm output. The optoelectronics module shall provide a means for adjusting the low-intensity alarm set point by one individual and without the necessity for an electrical disconnection. The low-intensity alarm set point adjustments shall be labeled and shall be accessible when the optoelectronics enclosure cover (for mounting Type A and Type B) is removed. The low-intensity alarm level set point shall allow tamperproof sensitivity adjustment over the entire dynamic range of the optoelectronics module. The optoelectronics module low-intensity alarm shall allow for an indication that maintenance is required before a false open switch indication.

S1.7.9 Electrical Overload Protection and Isolation—The optoelectronics module shall be provided with overload and short circuit protection. As a minimum, ac switches shall be protected from continuous overloads up to 6-A rms. Interruption of the operating voltage shall be required to restore normal operation of the switch after an overload has been detected. A means of isolating the optoelectronics module from ship power shall be provided on the unit.

S1.7.10 Wire Colors:

S1.7.10.1 ac Switches—Wire colors shall be as follows:

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black</td>
<td>= input</td>
</tr>
<tr>
<td>White</td>
<td>= output</td>
</tr>
<tr>
<td>Red</td>
<td>= normally open (N.O.) output</td>
</tr>
<tr>
<td>Green</td>
<td>= dc power high (positive lead)</td>
</tr>
<tr>
<td>White</td>
<td>= normally closed (N.C.) output</td>
</tr>
<tr>
<td>Black</td>
<td>= dc power low (negative lead)</td>
</tr>
</tbody>
</table>

S1.7.11 Lubrication—The fiber-optic position switch shall not require lubrication.

S1.7.12 Weight—The weight of the fiber-optic position switch shall not exceed 4.5 kg (10 lb).

S1.7.13 Dimensions—The critical dimensions of the fiber-optic position switch shall be as specified in the acquisition requirements (see S1.5.2).

S1.8 Performance Requirements

S1.8.1 Reliability—The fiber-optic position switch shall be constructed for a service life of no less than 40 000 h.

S1.8.1.1 Switch Electrical Characteristics—Fiber-optic position switches shall operate on either ac or dc power as specified in the part designation (see S1.5.2)

S1.8.2 ac Switch Electrical Characteristics—ac switches shall be two-wire devices and shall operate in series with the load. ac switches shall be selectable between normally open or normally closed configuration.

S1.8.2.1 Operating Voltage—The switch shall be designed to operate using 115-V, 60-Hz, single-phase, ungrounded, ac power as defined in MIL-STD-1399, Section 300. The switch shall operate with power supply variations as specified in S1.11.9 and S1.11.10. Full-time surge protection shall be provided for power supply limits.

S1.8.2.2 Voltage Drop—The voltage drop across each switch during the activated (ON) state shall not be greater than 4-Vac root mean square (rms) at rated load current.

S1.8.2.3 Leakage Current—The leakage current through each switch during the deactivated (OFF) state shall not be greater than 2-mA rms.

S1.8.2.4 Load Ratings—The switch load ratings shall be as specified in S1.8.2.5 through S1.8.2.7.

S1.8.2.5 Resistive—The switch shall have a resistive rating of 1.25.

S1.8.2.6 Inductive—The switch shall operate inductive loads with a power factor between 1 and 0.35. As a minimum, the switch shall have a make-current rating of 10-A rms for three cycles of the specified operating voltage and a break current rating of 1.25-A rms.

S1.8.2.7 Minimum Load—The switch shall operate with a minimum load of 15-mA rms.

S1.8.3 Multiple ac Switch Operation:

S1.8.3.1 Series Connection—When two ac switches of the same designation (see S1.4.1) are operated in series, the total...
switch voltage drop at the load shall not be greater than 8-Vac rms at the rated load current.

S1.8.3.2 Parallel Connection—When two ac switches of the same designation (see S1.4.1) are operated in parallel, the total switch leakage current at the load shall not be greater than 4-mA rms.

S1.8.4 dc Switch Electrical Characteristics—dc switches shall be four-wire devices and shall operate as voltage sources. Switches shall be line powered and shall have solid-state outputs. Each switch shall have one normally open (N.O.) and one normally closed (N.C.) output in a complementary configuration. The total power drawn from the line shall not be greater than the sum of 50 mA plus the output load current.

S1.8.4.1 Operating Voltage—The switch shall be designed to operate using 28 ± 4.5 V. The switch shall operate with power supply variations as specified in S1.11.9 and S1.11.10. Full-time surge protection shall be provided for power supply limits.

S1.8.4.2 Voltage Drop—The voltage drop across each switch during the activated (ON) state shall not be greater than 1.5 Vdc at rated load current.

S1.8.4.3 Leakage Current—Leakage current from each output in the open (OFF) state shall not be greater than 300 µA with 35 Vdc applied to the switch.

S1.8.5.4 Load Ratings—The switch load ratings shall be as specified in S1.8.5.5 through S1.8.5.6.

S1.8.5.5 Maximum Current—The switches shall operate continuously and supply 250 mA to resistive and inductive loads and 100 mA into lamp loads. The inductive load shall have a decay time of not greater than 100 ms when the load is interrupted. This decay shall be measured from the 90 % level to the 10 % level.

S1.8.5.6 Minimum Load—The switches shall supply any load current from maximum (see S1.8.5.5) down to zero.

S1.8.5 Multiple dc Switch Operation:

S1.8.5.1 Series Connection—When two dc switches of the same designation (see S1.4.1) are operated in series, the total switch voltage drop at the load shall not be greater than 3 Vdc at the rated load current.

S1.8.5.2 Parallel Connection—When two dc switches of the same designation (see S1.4.1) are operated in parallel, the total switch leakage current at the load shall not be greater than 600 µA.

S1.8.6 Switch Performance:

S1.8.6.1 Operation—The switch shall operate as specified in S1.7.7, S1.7.8 and S1.8.1.1.

S1.8.6.2 Response Time—Response time is the time it takes to go from 10 to 90 % of full rise. The response time of the opto-electronics module shall be no greater than 100 ms closed to open and 100 ms open to closed.

S1.8.6.3 Warm-Up Time—The switch shall operate properly as specified in S1.7.7 and S1.8.1.1 within 1 min.

S1.8.6.4 Change in Optical Transmittance—Changes in optical transmittance shall not be greater than 3 dB.

S1.8.6.5 Dynamic Range—The dynamic range of the optoelectronics module shall not be less than 30 dB.

S1.8.6.6 Ambient Light Susceptibility—The switch shall not indicate a false closed condition when the switch is open nor a false open condition when the switch is closed in the presence of ambient light.

S1.8.6.7 Steady-State Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The switch shall perform in accordance with S1.8.6.1 and shall not indicate a false open condition when the switch is closed, nor shall it indicate a false closed condition when the switch is open, when operated within the limits of steady-state voltage.

S1.8.6.8 Transient Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The switch shall perform in accordance with S1.8.6.1 and shall not indicate an open switch condition at any time when exposed to the specified limits of transient voltage and frequency.

S1.8.6.9 Insulation Resistance—The insulation resistance of the optoelectronics module shall not be less than 10 MΩ.

S1.8.6.10 Power Interruption—The switch shall perform in accordance with S1.8.6.1 and shall not indicate an open switch condition during steady-state operation when exposed to repeated power interruptions.

S1.8.6.11 Short Circuit—The switch shall perform in accordance with S1.8.6.1 and the local status indication shall indicate the correct switch position when experiencing a shorted output circuit.

S1.8.6.12 Line Voltage Reversal (dc Switch Only)—The switch shall operate in accordance with S1.8.6.1 after the input power leads have been reversed.

S1.8.6.13 Mechanical Life—The switch shall operate in accordance with S1.8.6.1 and S1.8.6.4 for a minimum of 260 000 cycles. The switch shall show no evidence of physical damage.

S1.8.6.14 Temperature—The sensor head and optoelectronics module shall operate within the optical limits specified in S1.8.6.4 when exposed to the specified temperature limits. The switch shall show no evidence of physical damage.

S1.8.6.15 Enclosure—The sensor head and optoelectronics module shall meet all test criteria in NEMA Standard 250 for Type 4X enclosures.

S1.8.6.16 Vibration—The sensor head and optoelectronics module shall meet the requirements of S1.8.6.1 and S1.8.6.4 when exposed to vibration in accordance with MIL-STD-167-1. The switch shall show no evidence of physical damage.

S1.8.6.17 Shock—The switch shall operate within the requirements of S1.8.6.1 and S1.8.6.4 when exposed to shock in accordance with MIL-S-901. Minor deformation of the switch is acceptable provided the sensor operates in accordance with S1.8.6.1 after shock. The switch shall not indicate a change in state for greater than 50 ms during shock.

S1.8.6.18 Electromagnetic Interference (EMI)—The switch shall perform within the limits of S1.8.6.1 and S1.8.6.4 and shall not indicate a change in state at any time when exposed to EMI in accordance with MIL-STD-461 Table II, except as modified below:

CE101—The test signal shall be applied only to the ac power leads of the test sample.

CE102—The test signal shall be applied only to the ac power leads of the test sample.
CS114—Only Limit Curve No. 2 shall apply with the frequency range limited to 10 kHz to 30 MHz.
RE101—Only the limit curve for 50 cm shall apply.
RS103—The frequency range shall be limited to 10 kHz to 18 GHz with an electric field strength test level of 10 V/m.

S1.9 Workmanship, Finish, and Appearance
S1.9.1 Surface Finish—Surfaces of castings, forgings, molded parts, stampings, and machined and welded parts shall be free of defects such as cracks, pores, undercuts, voids, and gaps, as well as harmful or extraneous materials such as sand, dirt, fins, sharp edges, scale, and flux. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn through, warpage, or dimensional change as a result of heat from welding. There shall be no damage to adjacent parts resulting from welding.

S1.10 Number of Tests and Retests
S1.10.1 First-Article Test Sample Size—A sample shall consist of a sensor head (Type 1 through 5), an optoelectronics module, associated fiber-optic cable, connectors, bulkhead adapters, and connector receptacles. Four samples of the same test lot (see S1.10.1.1) shall be subjected to first-article tests. Each sample shall be supplied with the length of cable required for the application (see S1.5.2) or 30 m of fiber-optic cable, whichever is greater. Note that two items will be tested at the same time: the optoelectronics module and the sensor head, whether proximity or limit. Prior testing of an optoelectronics module in conjunction with the testing of a different sensor head does not exclude the optoelectronics module from any of the testing requirements specified herein. Three samples shall be subjected to the tests of Group I and one sample shall be subjected to the tests of Group II.

S1.10.1.1 First-Article Test Lot—A test lot shall consist of all fiber-optic switches of the same classification (see S1.4.1), produced under essentially the same conditions, in the same facility from the same materials and offered for delivery at the same time.

S1.10.2 Conformance Test Sample Size—Fiber-optic switches offered for delivery shall be subjected to Group A tests listed in Table S1.1. The number of samples subjected to Group B tests shall be in accordance with Table S1.2.

S1.11 Test Methods
S1.11.1 Test Conditions—Except where the following factors are the variables, the tests specified in S1.11.2 shall be conducted with the equipment under the following operating environmental conditions:

<table>
<thead>
<tr>
<th>TABLE S1.1 Conformance Tests</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Test</strong></td>
</tr>
<tr>
<td>General examination</td>
</tr>
<tr>

</tr>
<tr>
<td>Temperature</td>
</tr>
<tr>
<td>Enclosure</td>
</tr>
</tbody>
</table>

(a) Ambient temperature shall be 23 ± 2°C.
(b) Relative humidity shall be ambient.

S1.11.2 Tests—Except for the warm-up time test (see S1.11.5), the switch and all associated test equipment shall be energized for a period of time sufficient to ensure complete warm-up.

S1.11.3 Operation—The operation of the sensor head and optoelectronics module shall be tested by manually opening and closing the switch for ten cycles. Performance shall be in accordance with S1.8.6.1.

S1.11.4 Response Time—The response time shall be measured by opening and closing the switch via a beam gate, controlled by a function generator. The output of the switch shall be connected to a calibrated optical oscilloscope or a calibrated electrical oscilloscope as appropriate. The output from the function generator shall be connected to the monitoring oscilloscope and the traces shall be compared to determine the response time of the system. Performance shall be in accordance with S1.8.6.2.

S1.11.5 Warm-Up Time—The switch shall be deenergized for a period of not less than 12 h. The switch shall then be energized. The warm-up time is the elapsed time between the application of line power and the point at which the switch output reaches the conditions specified in S1.8.6.3. Performance shall be in accordance with S1.8.6.3.

S1.11.6 Change in Optical Transmittance—The change in optical transmittance of the sensor head shall be performed in accordance with EIA 455-20. Performance shall be in accordance with S1.8.6.4.

S1.11.7 Dynamic Range—A calibrated optical attenuator with two jumpers shall be tested for insertion loss in accordance with EIA 455-34. The attenuator shall then be connected to the transmitter and receiver via the two jumper cables. The attenuation shall be increased from 0 dB (plus insertion loss of attenuator and jumpers) to 50 dB (plus insertion loss of attenuator and jumpers). The switch shall be left in the open position. The dynamic range will be exceeded when the switch indicates a closed switch position. The dynamic range shall be in accordance with S1.8.6.5.

S1.11.8 Ambient Light Susceptibility—The ambient light source and general test conditions shall be in accordance with EIA 455-22. The entire switch shall be placed in the beam of the light source and placed in a closed condition. After a period of 10 min, the switch shall be placed in an open condition by disconnecting the optical cable from the source. The switch...
shall then be subjected to the ambient light source for an additional 10 min. Performance shall be in accordance with S1.8.6.6.

S1.11.9 Steady-State Supply Voltage and Frequency (ac) and Supply Voltage (dc)—The switch shall be operated for not less than 15 min and shall be manually opened and closed not less than ten times at conditions of nominal, maximum, and minimum steady-state voltages (dc) and all possible combinations of nominal, maximum, and minimum steady-state voltages and frequencies (ac). Each of the conditions shall be tested at 0 ± 2°C, 25 ± 2°C, and 60 ± 2°C. This test may be performed in conjunction with the temperature test (see S1.11.18). The switch shall be allowed to stabilize at each testing temperature before the steady-state voltage and frequency test shall be performed. Performance shall be in accordance with S1.8.6.7.

S1.11.10 Transient Supply Voltage and Frequency (ac) or Supply Voltage (dc)—The switch shall be tested to S1.11.11 (ac) or S1.11.12 (dc). The switch shall be placed in a closed switch position and the output of the switch shall be monitored throughout the test. Performance shall be in accordance with S1.8.6.8.

S1.11.11 Transient Supply Voltage and Frequency (ac)—The test shall be performed as follows:
(a) With the switch operating at steady-state voltage of 123 Vac, the voltage shall be increased to 138 Vac, and then decreased back to the steady-state voltage of 123 Vac in a 2-s period.
(b) With the switch operating at a steady-state voltage of 107 Vac, the voltage shall be decreased to 92 Vac, and then increased back to the steady-state voltage of 107 Vac in a 2-s period.
(c) With the switch operating at a steady-state frequency of 62 Hz, the frequency shall be increased to 63.5 Hz, and then decreased back to the steady-state frequency of 62 Hz in a 2-s period.
(d) With the switch operating at a steady-state frequency of 58 Hz, the frequency shall be decreased to 56.5 Hz, and then increased back to the steady-state frequency of 58 Hz in a 2-s period.

S1.11.12 Transient Supply Voltage (dc)—The test shall be performed as follows:
(a) With the switch operating at a steady-state voltage of 32.5 Vdc, the voltage shall be increased to 34.5 Vdc, and then decreased back to the steady-state voltage of 32.5 Vdc in a 2-s period.
(b) With the switch operating at a steady-state voltage of 23.5 Vdc, the voltage shall be decreased to 21.5 Vdc, and then increased back to the steady-state voltage of 23.5 Vdc in a 2-s period.

S1.11.13 Insulation Resistance—The insulation resistance of the optoelectronics module shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and ground. The temperature shall be 25 ± 5°C and the relative humidity shall be 50 ± 10%.

requirements (see S1.8.6.9) and is steady or increasing, the test may be terminated before the end of the 2-min period. Performance shall be in accordance with S1.8.6.9.

S1.11.14 Power Interruption—The switch shall be placed in a closed switch position and the output of the switch shall be monitored throughout the test. With the switch operating within the steady-state tolerances of voltage and frequency, the external power supply shall be suddenly interrupted, and after an interval between 3 and 4 s, the power supply shall be reestablished to within the steady-state tolerances. After the switch has been operated long enough to detect any major performance degradation, the power shall be interrupted for an interval of 30 s. This cycle (3- to 4-s interruption, monitor, then 30-s interruption) shall be repeated three times (total of four). Performance shall be in accordance with S1.8.6.10.

S1.11.15 Short Circuit—The switch shall be deenergized. The electrical output leads or terminals of the optoelectronics module shall be connected directly together with no load resistance. The switch shall be energized for 5 min. The switch shall be manually opened and closed ten times during this period. Immediately following the 5-min period, the output pins shall be unshorted. Performance shall be in accordance with S1.8.6.11.

S1.11.16 Line Voltage Reversal (dc)—The switch power supply shall be connected as follows: the positive 28-Vdc signal shall be applied to connector Pin “B.” The dc reference signal shall be applied to connector Pin “A.” The power supply shall be energized for a period of 10 min and shall then be disconnected. The power supply shall then be correctly applied (Pin “A” positive, Pin “B” negative). Performance shall be in accordance with S1.8.6.12.

S1.11.17 Mechanical Life—The switch shall be placed in the closed switch condition. The switch shall then be operated for 260 000 cycles (open-close is one cycle). The cycle rate shall be between one cycle per s and one cycle every 2 s (1 to 0.5 Hz). A change in optical transmittance test (see S1.11.6) shall be performed at the end of the mechanical life test. Performance shall be in accordance with S1.8.6.13.

S1.11.18 Temperature—The mated cable to switch assemblies shall be tested at high and low temperature as specified herein. The switch shall be placed in a closed switch position and Steps 1 through 6 shall be performed. The switch shall then be placed in an open switch position and Steps 1 through 6 shall be performed. Change in optical transmittance shall be measured in accordance with S1.11.6. Visual inspection shall be performed after the test. Performance shall be in accordance with S1.8.6.14.

Step 1—Hold temperature at room ambient (25 ± 2°C) for one h.
Step 2—Decrease temperature in steps of 10°C at 30 min per step until −28 ± 2°C is achieved.
Step 3—Hold temperature at −28 ± 2°C for 24 h.
Step 4—Increase temperature in steps of 10°C at 30 min per step until 65 ± 2°C is achieved.
Step 5—Hold temperature at 65 ± 2°C for 24 h.
Step 6—Decrease temperature in steps of 10°C at 30 min per step until 25 ± 2°C is achieved.
S1.11.19 Enclosure—The sensor head and optoelectronics module shall be subjected to the tests in NEMA 250 for Type 4X enclosures. Change in optical transmittance shall be measured in accordance with S1.11.6. Performance shall conform to the requirements of S1.8.6.15.

S1.11.20 Vibration—The switch shall be placed in a closed switch position and the output of the switch shall be monitored throughout the test. The switch shall be tested in accordance with MIL-STD-167-1 Type I vibration test. Change in optical transmittance shall be measured in accordance with S1.11.6. Visual inspection shall be performed after the test. Performance shall be in accordance with S1.8.6.16.

S1.11.21 Shock—The switch shall be subjected to the high-impact shock test for Grade A, Type A, Class I, lightweight equipment as specified in MIL-S-901. The switch shall be placed in a closed switch position and the switch shall be monitored throughout the test. The change in optical transmittance shall be measured after each of the nine hammer blows (see S1.11.6). Performance shall be in accordance with S1.8.6.17.

S1.11.22 Electromagnetic Effects—The switch shall be tested in accordance with MIL-STD-461. The switch shall be placed in a closed switch position and the output of the switch shall be monitored throughout the test. Performance shall be in accordance with S1.8.6.18.

S1.12 Inspection

S1.12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:
(a) First-article tests (see S1.12.2).
(b) Conformance tests (see S1.12.3).

S1.12.2 First-Article Tests—When first-article tests are required in the acquisition requirements (see S1.5.2), first-article tests shall be performed before production. First-article tests shall be performed on samples that have been produced with equipment and procedures normally used in production. First-article tests shall consist of the tests specified in Table S1.3. Failure of any switch to meet the requirements of this specification shall be cause for rejection.

S1.12.2.1 Order of First-Article Tests—Test specimens shall be subjected to the tests specified in Table S1.13 in the order listed except that the steady-state supply voltage and frequency test may be performed concurrently with the temperature test. Any deviation in the test order shall first be approved by the purchaser.

S1.12.3 Conformance Tests—All switches shall be subjected to conformance tests. Conformance tests shall be in accordance with Table S1.1 and S1.10.2. Failure of any switch to meet the requirements of this specification shall be cause for rejection.

S1.12.4 General Examination—Each fiber-optic position switch shall be examined to determine conformance to the requirements of this specification with respect to material, color, finish, workmanship, safety, construction, assembly, dimensions, weight, identification marking, and label plates. Examination shall be limited to the examinations that may be performed without disassembling the unit in such a manner that its performance, durability, or appearance would be affected. Examination shall include a check of all controls and adjustments, as applicable.

S1.13 Certification

S1.13.1 The purchase order or contract should specify whether the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this standard and the requirements have been met. The purchase order or contract should specify when a report of the test results shall be furnished. Otherwise, the purchase order or contract should specify that all test data remain on file for three years at the manufacturer’s facility for review by purchaser upon request.

S1.14 Product Marking

S1.14.1 Identification Marking—Special purchaser specified product marking shall be listed in the acquisition requirements (see 5.2). Switches shall be permanently and legibly marked. Marking shall be located on the top or front of the sensor head (as mounted in service), and on the top or front of the optoelectronics module (as mounted in service).

S1.14.1.1 Sensor Head—At a minimum, the information specified in 14.1.1 in addition to the following shall be marked on the sensor head:
(a) National stock number (NSN).
(b) Technical manual number, and
(c) Contract number.

S1.14.2 Labeling—Labels with yellow lettering on a black background shall be provided as follows:
S1.14.2.1 Optoelectronics Module—A visible label shall be affixed to the outside of the optoelectronics module cover and shall contain the following:

**WARNING**
UNTERRMINATED OPTICAL CONNECTIONS MAY EMIT LASER RADIATION
DO NOT VIEW BEAM WITH OPTICAL INSTRUMENTS AND AVOID DIRECT EXPOSURE TO THE BEAM
S1.14.2.2 Sensor Head and Inside of Optoelectronics Module—A visible label shall be affixed to the sensor head and the inside of the optoelectronics module and shall contain the following:

WARNING
INVISIBLE LASER RADIATION
AVOID EXPOSURE TO THE BEAM

S1.15 Packaging and Package Marking
S1.15.1 Packaging and package marking shall be in accordance with Section 15.

S1.16 Quality Assurance
S1.16.1 Warranty—Special warranty requirements shall be specified in the acquisition requirements (see S1.5.2).
Standard Specification for Packing, Fiberglass, Braided, Rope, and Wick

This standard is issued under the fixed designation F 2087; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope
1.1 This specification covers the general requirements and tests for braided, rope, and wick fiberglass packing used for boiler, furnace, and other high-temperature equipment seals for service temperatures up to 1000°F (538°C).

2. Referenced Documents
2.1 ASTM Standards:
D 578 Specification for Glass Fiber Strands
D 3951 Practice for Commercial Packaging
D 4268 Test Methods for Testing Fiber Ropes

3. Terminology
3.1 Braided fiberglass—A braid constructed of continuous fiberglass strands.
3.2 Plied—A yarn product produced by twisting together two or more ends of single fiberglass yarns.
3.3 Strand—An ordered assemblage of textile fibers having a high ratio of length to diameter and normally used as a unit, including slivers, rovings, single yarns, plied yarns, cords, braids, ropes, and so forth.
3.4 Yarn—Portion of fiberglass reduced to thread to obtain a fine and thin strand.
3.5 Lot—Unless otherwise specified herein, a lot should consist of all finished packing of one type and size produced in a continuous run or at the same time under essentially the same conditions. The sampling unit should be one spool, reel, or coil of packing as necessary to enable performance of the required examinations or tests.

4. Classification
4.1 Classification—The material shall be of the following types as specified (see 5.1):
Type I—Wick
Type II—Rope
Type III—Braided

5. Ordering Information
5.1 Acquisition Requirements—Acquisition documents must specify the following:
(a) Title, number, and date of this specification;
(b) Type, size, and weight of spool, reel, or coil required (see Section 7);
(c) Marking requirements (see Section 15);
(d) Packaging requirements (see Section 16);
(e) Performance requirements; and
(f) Inspection, testing, and certification of the material should be agreed upon between the purchaser and the supplier as part of the purchase contract (see Sections 12 and 14).

6. Materials and Manufacture
6.1 Material—The material shall be a continuous, high-density-type ETG fiberglass material (see Specification D 578). Asbestos and components containing asbestos are prohibited.
6.2 Construction—The packing shall be composed of twisted plied strands made into a braided packing or laid up into the general form of a wick or a loosely twisted rope according to the manufacturer’s design. If a core is used, it shall be of the same material and construction.

7. Dimensions and Tolerances
7.1 Type I Wick Packing—Unless otherwise specified (see 5.1), the packing shall come in 13-lb (5.9-kg) or 25-lb (11.3-kg) spools, reels, or coils in the sizes listed in Table 1.
7.2 Type II Rope Packing—Unless otherwise specified (see 5.1), the packing shall come in 25-lb (11.3-kg) or 50-lb (22.7-kg) spools, reels, or coils in the sizes listed in Table 2.
7.3 Type III Braided Packing—Unless otherwise specified (see 5.1), the packing shall come in 25-lb (11.3-kg) or 50-lb (22.7-kg) spools, reels, or coils in the sizes listed in Table 3.

8. Workmanship
8.1 Workmanship—The packing should be free from extraneous material and visible defects that may affect its serviceability.
9. Quality Assurance

9.1 Quality Systems—Suppliers shall be prepared to document use of a quality system such as compliance with an ISO 9000 series program or similar program.

10. Specimen Preparation

10.1 Specimen Preparation—Purchaser and supplier should agree on specimen preparation.

11. Test Methods

11.1 Material—Material shall be tested in accordance with Specification D 578.

11.2 Size—Material shall be measured using a flexible measuring tape such as the one described in Test Methods D 4268 and shall be in accordance with the size specified in Table 1, Table 2, or Table 3.

11.3 Splices—Unless otherwise agreed upon, there shall be allowed a maximum of two splices per unit with no piece shorter than 10 ft in length.

11.4 Weight—Material shall be weighed in accordance with Table 1, Table 2, or Table 3 using a weighing scale, accurate to ±0.25 related to the real division of the graduated line. This value is expressed in mass unit of:

(a) the difference between the corresponding values of marks of the graduated line and

(b) the difference between two consecutive indications for digital indication.

12. Inspection and Testing

12.1 Inspection and testing of the material should be agreed upon between the purchaser and the supplier as part of the purchase contract (see 5.1).

13. Rejection

13.1 Materials that fail to conform to the requirements of this specification shall be rejected. Rejection should be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of testing, the producer may make claim for a rehearing or provide for third party testing.

14. Certification

14.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished (see 5.1).

15. Product Marking

15.1 Marking—For commercial shipment, marking should be in accordance with accepted industry practices or as required in the purchase contract (see 5.1).

15.1.1 When specified, a part-numbering system shall be used in accordance with Appendix X1.

16. Packaging

16.1 Commercial Packaging—Commercial packaging should be in accordance with Practice D 3951 or as required in the purchase contract (see 5.1).
X1. PART-NUMBERING SYSTEM

X1.1 Part numbers for fiberglass packing shall include the number of this standard followed by the size shown in Table 1, Table 2 or Table 3. An example of this system is in Fig. X1.1.

![Part-Numbering System Diagram]

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Test Methods for Determining Effects of Large Hydrocarbon Pool Fires on Insulated Marine Bulkheads and Decks, Constructed of Steel

1. Scope

1.1 These test methods described in this fire-test response standard are used for determining the fire-test response of insulated marine steel bulkheads and decks. The insulation is either homogeneous or composite construction.

1.2 It is the intent that tests conducted in accordance with these test methods will indicate whether bulkheads and decks will continue to perform their intended function during the period of fire exposure. These test methods shall not be construed as implying suitability for use after fire exposure.

1.3 These test methods prescribe a standard fire exposure for comparing the relative performance of different bulkhead and deck assemblies under controlled laboratory conditions. The application of these test results to predict the performance of actual assemblies when exposed to large pool fires requires a careful engineering evaluation.

1.4 Limitations—These test methods do not provide the following:

1.4.1 Full information on the performance of assemblies constructed with components or of dimensions other than those tested.

1.4.2 An evaluation of the degree to which the assembly contributes to the fire hazard through the generation of smoke, toxic gases, or other products of combustion.

1.4.3 Measurement of flame spread over the surface of the test assembly.

1.4.4 The erosive effect that the velocities or turbulence, or both, generated in large pool fires has on some fire protection materials.

1.4.5 Full information on the performance of assemblies at times less than 5 min because the rise time called out in Section 6 is longer than that of a real fire.

1.5 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for approximate information only.

1.6 This standard measures and describes the response of materials, products, or assemblies to heat and flame under controlled conditions, but does not by itself incorporate all factors required for fire hazard or fire-risk assessment of the materials, products, or assemblies under actual fire conditions.

1.7 This test method is based on the fire exposure as defined in Test Methods E 1529 (issued by the Committee on Fire Standards, E05).

1.8 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

E 119 Test Methods for Fire Tests of Building Construction and Materials

E 176 Terminology of Fire Standards

E 511 Test Method for Measuring Heat Flux Using a Copper-Constantan Circular Foil, Heat-Flux Gage

E 1529 Test Methods for Determining Effects of Large Hydrocarbon Pool Fires on Structural Members and Assemblies

3. Terminology

3.1 Definitions of Terms Specific to These Test Methods—Refer to Terminology E 176 for definitions of terms associated with fire issues used in these test methods.

4. Summary of Test Methods

4.1 The fire environment within the furnace shall develop a total heat flux of $204 \pm 6 \text{ kW/m}^2$ ($65000 \pm 5000 \text{ Btu/ft}^2 \cdot \text{h}$) and an average temperature of $1093 \pm 111^\circ \text{C}$ ($2000 \pm 200^\circ \text{F}$) within 5 min from the start of the test. The fire environment shall be controlled by reproducing the furnace temperatures recorded during the furnace calibration method specified in Section 7. This temperature shall be maintained throughout the remainder of the fire test as shown in Fig. 1.

4.2 Performance is defined as the time period during which bulkheads and decks will continue to perform their intended...
5. Significance and Use

5.1 These test methods are intended to provide a basis for evaluating the time period during which bulkheads and decks will continue to perform its intended function when subjected to a controlled, standardized fire exposure.

5.1.1 In particular, the selected standard exposure condition simulates the condition of total continuous engulfment of a member or assembly in the luminous flame (fire plume) area of a large free-burning fluid hydrocarbon pool fire. The standard fire exposure is basically defined in terms of the total flux incident on the test specimen together with appropriate temperature conditions.

5.1.2 It is recognized that the thermodynamic properties of free-burning, hydrocarbon fluid pool fires have not been completely characterized and are variable depending on the conditions, the physical relationship of the structural member to the exposing fire, and other factors. As a result, the exposure specified in these test methods is not necessarily representative of all the conditions that exist in large hydrocarbon pool fires. The specified standard exposure is based upon the best available information and testing technology. It provides a basis for comparing the relative performance of different assemblies under controlled conditions.

5.1.3 It is feasible that substantial changes in the fire performance characteristics of the assembly will result from any variation from the construction or conditions (that is, size, method of assembly, and materials) that are tested.

5.2 The structural assemblies that will be evaluated in accordance with these test methods will be located on a ship.

6. Furnace Control

6.1 The fire environment within the furnace shall develop a total heat flux of 204 ± 16 kW/m² (65 000 ± 5 000 Btu/ft²-h) and an average temperature of 1093 ± 111°C (2000 ± 200°F) within 5 min from the start of the test. The fire environment shall be controlled by reproducing the furnace temperatures recorded during the furnace calibration method specified in Section 7. This temperature shall be maintained throughout the remainder of the fire test as shown in Fig. 1.

6.2 The furnace shall be controlled to maintain the area under the time-temperature curve to within 10% of the corresponding area under the standard time-temperature curve shown in Fig. 1 for fire tests of 60-min or less duration; to within 7.5% for test longer than 60 min but not longer than 120 min; and to within 5% for tests exceeding 120 min in duration. The area under the time-temperature curve shall be obtained by averaging the results of thermocouple readings.

6.3 A correction will be applied for variation of the furnace exposure from the prescribed, where such variation will affect the test results, by multiplying the indicated time period by two thirds of the value obtained by dividing the difference in area between the curve of average furnace temperature and the standard curve for the first three fourths of the period by the area between the standard curve above a baseline of 20°C (68°F) for the same part of the indicated period during the first part of the test. For fire exposure times longer than standard, it is feasible that the indicated rating period will be increased by the amount of the correction, and for fire exposure times less than standard, the indicated rating period may be similarly decreased. The correction will be expressed by the following formula:

\[ C = \frac{2I(A - A_s)}{3(A_s)} \]  

where:

- \( C \) = correction in the same units as \( I \),
- \( I \) = indicated fire-resistance period,
- \( A \) = area under the curve of indicated average furnace temperature for the first three fourths of the indicated period, and
- \( A_s \) = area under the standard furnace curve for the same part of the indicated period.

6.4 The temperature fixed by the furnace calibration (see Section 7) shall be the average temperature obtained from the readings of five thermocouples symmetrically disposed and...
distributed within the test furnace to show the temperature near all parts of the assembly.

6.5 The thermocouples shall be fabricated by fusion-welding the twisted ends of (0.064-in.) diameter (No. 14 B & S gage) chromel-alumel wires having a time constant of 2 min or less, and mounting the wires in porcelain insulators. The thermocouple assembly shall be inserted through a standard weight, nominal 13-mm (½-in.) iron, steel, or inconel pipe, and the end of the pipe from which the welded junction protrudes is to be open. The thermocouple junction shall protrude 13 mm (½ in.) from the open end of the pipe.

6.6 The junction of the thermocouples shall be placed 102 mm (4 in.) away from the exposed face of the test specimen and located at the ½ and ¾ heights of the test specimen.

6.7 Each thermocouple within the furnace shall be recorded at intervals not exceeding 1 min.

7. Calibration of Furnace

7.1 A furnace calibration record shall be maintained and the furnace shall be recalibrated after completion of any repair that could alter the heat generation, retention, or flow characteristics of the furnace.

7.2 The temperature of the furnace shall be measured by five thermocouples. They shall be located as shown in Fig. 2.

7.3 The measured values of all thermocouples and calorimeters shall be recorded at intervals not exceeding 1 min.

7.4 The thermocouples used to measure the temperatures on the face of the calibration wall shall be No. 28 gage, Type K inconel sheathed thermocouples having a time constant of 0.5 s or less. The thermocouple junction shall be located 6.3 mm (¼ in.) from the face of the calibration wall.

7.5 The thermocouples used to measure the temperatures within the furnace shall be constructed as described in 6.5.

7.6 The calorimeters shall have a minimum range from 315 kW/m² (100 000 Btu/ft²·h) and a 180° view angle. They shall be located as shown in Fig. 2.

7.7 The fire environment during the calibration test shall comply with the requirements of 6.1. The length of the calibration test shall be 60 min.

7.8 Individual total heat flux measurements shall lie within the limits shown in Fig. 3.

7.9 The average furnace temperature shall be determined by averaging the temperatures recorded by the five thermocouples placed 102 mm (4 in.) from the specimen. The average shall be 1093 ± 111°C (2000 ± 200°F) and individual temperatures are to be 1093 ± 219°C (2000 ± 400°F) 5 min after the start of the test and until the end of the test.

7.10 The average furnace temperature curve shall be reproduced to maintain the furnace control described in Furnace Control, Section 6.

7.11 A record of the temperatures measured near the face of the wall and the oxygen content shall be retained by the testing laboratory on file for a period of ten years.

8. Furnace Pressure

8.1 A linear pressure gradient exists over the height of furnace, and although the gradient will vary slightly as a function of the furnace temperature, a mean value of 8 Pa/m height shall be assumed in assessing the furnace pressure conditions. The value of the furnace pressure shall be the nominal mean value, disregarding rapid fluctuation of pressure outside the furnace at the same height. It shall be monitored and controlled continuously and by 5 min from the commencement of the test shall be achieved within ±3 Pa, see Fig. 4 for design of the T-shaped sensor.

8.2 For vertically orientated specimens, the furnace should be operated such that a pressure of zero is established at a height of 500 mm above the notional floor level to the test specimen. However, for specimens with a height greater than 3 m, the pressure at the top of the test specimen shall not be greater than 20 Pa, and the height of the neutral pressure axis shall be adjusted accordingly.

8.3 For horizontally orientated specimens, the furnace shall be operated such that a pressure of 20 Pa is established at a position 100 mm below the underside of the specimen.

9. Test Specimen

9.1 Bulkheads:

9.1.1 Dimensions:

9.1.1.1 The minimum overall dimensions for the test specimen including the perimeter details at the top, bottom, and vertical edges, are 2440-mm width and 2500-mm height.

9.1.1.2 The overall dimensions of the structural core shall be 20 mm less in both the width and the height than the overall dimensions of the specimen, and the other dimensions of the structural core shall be as follows:

| Thickness of plating: steel | 4.5 ± 0.5 mm |
| Stiffeners spaced: steel at 600 mm | 65 ± 5 × 65 ± 5 × 6 ± 1 mm |

9.1.1.3 The width of the structural core shall be greater than the specified dimensions providing that the additional width is in increments of 600 mm to maintain the stiffener centers and the relationship between the stiffeners and the perimeter detail.
9.1.1.4 Any joints in the plating shall be full-welded, at least from one side.

9.1.1.5 The construction of a structural steel core having the recommended dimensions is shown in Fig. 5; the thickness of the plating and dimensions of the stiffeners shown are nominal dimensions. Irrespective of the dimensions of the structural core and the material of manufacture, the details around the perimeter shall be as illustrated in Fig. 6.

9.2 Decks:

9.2.1 Dimensions:

9.2.1.1 The minimum overall dimensions for the test specimen including the perimeter details at all edges are 2440 mm in width and 3040 mm in length.

9.2.1.2 The overall dimensions of the structural core shall be 20 mm less in both the width and length than the overall dimensions of the specimen, and the other dimensions of the structural core shall be as follows:

- Thickness of plating: steel 4.5 ± 0.5 mm
- Stiffeners spaced: steel at 600 mm 100 ± 5 × 70 ± 5 × 8 ± 1 mm

9.2.1.3 The width of the structural core shall be greater than the specified dimensions providing that the additional width is in increments of 600 mm to maintain the stiffener center and the relationship between the stiffeners and the perimeter detail.

9.2.1.4 Any joints in the plating shall be full welded, at least from one side.

9.2.1.5 The construction of a structural steel core having the recommended dimensions is shown in Fig. 2; the thickness of the plating and dimensions of the stiffeners shown are nominal dimensions. Irrespective of the dimensions of the structural core and the material of manufacture, the details around the perimeter shall be as illustrated in Fig. 7.

10. Mounting of the Test Specimens

10.1 Restraint and Support Frames:

10.1.1 All test specimens shall be mounted within substantial concrete, or concrete or masonry-lined frames, which are capable of providing a high degree of restraint to the expansion forces generated during the test. The concrete or the masonry shall have a density between 1600 and 2400 kg/m³. The concrete or masonry lining to a steel frame shall have a thickness of at least 50 mm.

10.1.2 The rigidity of the restraint frames shall be evaluated by applying an expansion force of 100 kN within the frame at mid-width between two opposite members of the frame, and measuring the increase in the internal dimensions at these position. This evaluation shall be conducted in the direction of the bulkhead or deck stiffeners, and the increase of the internal dimension shall not exceed 2 mm.

10.2 Bulkheads and Decks:
10.2.1 The structural core to bulkheads and decks shall be fixed into the restraint frame and sealed around its perimeter as shown in Fig. 6. It is feasible that steel spacers, with an approximate thickness of 5 mm, will be inserted between the fixing cleats and the restraint frame if the laboratory finds this necessary.

10.2.2 When the structural core of a bulkhead or a deck is to be exposed to the heating conditions of the test, that is, when the fixing cleats are on the exposed side of the structural core, then a 100-mm-wide perimeter margin adjacent to the restraint frame shall be insulated such that the fixing cleats and the edges of the structural core are protected from direct exposure to the heating condition. In no other situations, irrespective of the type of test specimen, shall the perimeter edges be protected from direct exposure to the heating conditions.

11. Insulating the Test Specimen

11.1 Decks shall be insulated from below on the stiffener side. Insulation shall be on the exposed side.

11.2 For unrestricted use, bulkhead insulation shall be installed on the unexposed side.

11.3 If the insulation is installed on the unstiffened or stiffened exposed side, the use shall be restricted.

11.4 If the insulation is installed on both sides in identical details then the use shall be unrestricted. The unexposed face shall be the stiffened side of the test specimen.

11.5 If different insulation details are installed on both sides of the bulkhead, then the bulkhead shall be tested from both sides for unrestricted use.

12. Conditioning

12.1 General:

12.1.1 The test specimen shall not be tested until it has reached an air-dry condition. This condition is defined as an equilibrium (constant weight) with an ambient atmosphere of 50% relative humidity at 23°C (73°F).

12.1.2 Accelerated conditioning is permissible provided the test method does not alter the properties of component materials. In general, high-temperature conditioning shall be below temperatures critical for the materials.

12.2 Verification—The condition of the test specimen shall be monitored and verified by use of special samples for the determination that shall be so constructed as to materials, as appropriate. These samples shall be so constructed as to represent the loss of water vapor from the specimen by having
similar thicknesses and exposed faces. They shall have minimum linear dimensions of 300 by 300 mm (12 by 12 in.) and a minimum mass of 100 g. Constant weight shall be considered to be reached when two successive weighing operations, carried out at an interval of 24 h, do not differ by more than 0.3 % of the mass of the reference specimen or 0.3 g, whichever is the greater.

12.3 Encapsulated Materials—When the test specimen incorporates encapsulated materials, it is important to ensure that these materials have reached an equilibrium moisture content prior to assembly, and special arrangements shall be made with the applicant for the test to ensure that this is so.

13. Unexposed Face Temperature Thermocouples

13.1 Design—The temperature of the unexposed surface shall be measured by means of disk thermocouples of the type shown in Fig. 8. Thermocouple wires, 0.5-mm-thick noncombustible insulating pad. The pad material shall have a density of 900 ± 100 kg/m³.

13.2 Connection—Connection to the recording instrument shall be by wires of similar or appropriate compensating type.

13.3 Preparation of Surfaces to Receive Thermocouples:

13.3.1 Steel—Surface finishes shall be removed and the surface cleaned with a solvent. Loose rust and scale shall be removed by a wire brush.

13.3.2 Irregular Surfaces—A smooth surface not greater than 2500 mm², to provide adequate adhesive bond, shall be made for each thermocouple by smoothing the existing surface with a suitable abrasive paper. The material removed shall be the minimum to provide adequate bonding surface. Where the surface cannot be smoother, fillings shall be used of minimum quantity to provide a suitable surface. The filling shall comprise a ceramic cement, and when the filled surface is dry, it shall be smoothed, if necessary, with abrasive paper.

13.4 Fixing of Thermocouples:

13.4.1 Steel—The insulating pad with the thermocouple fitted shall be bonded to the cleaned surface of the steel using a water-based ceramic cement produced by integrating the components to form a high-temperature resistant adhesive. The adhesive shall be of such a consistency that no mechanical aid is necessary for retention purposes during the drying process, but where difficulty in bonding is experienced, it is feasible that

---

**NOTE 1**—Section 'A—A' (see Fig. 5 and Fig. 7).

**NOTE 2**—Section 'B—B' (see Fig. 5 and Fig. 7).
retention by adhesive tape will be used provided that the tape is removed sufficiently long in advance of removal of the tape to ensure that the insulating pad is not damaged. If the thermocouple pad is damaged when the tape is removed, then the thermocouple should be replaced.

13.4.2 **Mineral Wool**—The thermocouples with insulating pads fitted should be arranged in such a way that if a surface wire mesh is present it may aid retention, and, in all cases, the bond to the fibrous surface should be made using a contact adhesive. The nature of the adhesive necessitates a drying time before mating surfaces are put together, thus, obviating the need for external pressure.

13.4.3 **Mineral Fiber Spray**—Thermocouples should not be fitted until the insulation has reached a stable moisture condition. In all cases, the bonding technique for steel should be used, and, where a surface wire mesh is present, the thermocouples should be affixed to the insulation in such a way that the wire mesh aids retention.

13.4.4 ** Vermiculite/Cement-Type Spray**—The technique specified for mineral fiber spray shall be employed.

13.4.5 **Boards of Fibrous or Mineral Aggregate Composition**—The bonding technique for steel shall be used.

13.4.5.1 In all cases of adhesive bonding, the adhesive shall be applied in a thin film sufficient to give an adequate bond, and there should be a sufficient lapse of time between the bonding of the thermocouples and the test for stable moisture conditions to be attained in the case of the ceramic adhesive and evaporation of the solvent in the case of the contact adhesive.

13.5 **Positioning of Thermocouples on the Specimen**:

13.5.1 **Bulkheads and Decks**—The surface temperatures on the unexposed face of the test specimen shall be measured by thermocouples located as shown in Figs. 9 and 10:

13.5.1.1 Five thermocouples, one at the center of the test specimen and one at the center of each of the four quarters, all positioned no closer than 100 mm away from the nearest part of any joints welds or pins to any stiffeners;
13.5.1.2 Two thermocouples, one placed over each of the central stiffeners and positioned for a bulkhead at 0.75 height of the specimen, and positioned for a deck at mid-length of the deck;

13.5.1.3 Two thermocouples, each placed over a vertical (longitudinal) joint, if any, in the insulation system and positioned for a bulkhead at 0.75 height of the specimen and positioned for a deck at mid-length of the deck;

13.5.1.4 When a construction has two differently orientated joint details, for example normal to each other, then two thermocouples additional to those already described in 13.5.1.3 shall be used, one on each of two intersections;

13.5.1.5 When a construction has two different types of joint detail, then two thermocouples shall be used for each type of joint;

13.5.1.6 Additional thermocouples, at the discretion of the testing laboratory, shall be fixed over special features or specific construction details if it is considered that temperatures higher than those measured by the thermocouples previously listed are possible; and

13.5.1.7 The thermocouples specified in 13.5.1.4-13.5.1.6 for measurements on bulkheads, for example, over different joint types or over joint intersections, shall, where possible, be positioned in the upper half of the specimen.

14. Measurements and Observations on the Test Specimen During Test

14.1 Temperature:

14.1.1 The ambient air temperature at the beginning of the test shall be within the range from 10 to 32°C (50 to 90°F).

14.1.2 All temperature measurements shall be recorded at intervals not exceeding 1 min.

14.1.3 When calculating temperature rise on the unexposed surface of the test specimen, this shall be done on an individual thermocouple-by-thermocouple basis. The average temperature rise of the unexposed surface shall be calculated as the average of the rises recorded by the individual thermocouple used to determine the average temperature.

14.1.4 For bulkheads and decks, the average temperature rise on the unexposed face of the specimen shall be calculated from the thermocouples specified in 13.5.1.1 only.

14.2 Deformation—The maximum deflection of specimen shall be recorded during the test. These deflections and displacements shall be measured with an accuracy of ±2 mm.
14.3 General Behavior—Observations shall be made of the general behavior of the specimen during the course of the test and notes concerning the phenomena such as cracking, melting or softening of the materials, spalling or charring, and so forth, of materials of construction of the test specimen shall be made. If quantities of smoke are emitted from the unexposed face, this shall be noted in the report. However, the test is not designed to indicate the possible extent of hazard due to these factors.

15. Performance Criteria

15.1 The average unexposed face temperature rise as determined by averaging the five thermocouples as described in 13.5.1.1 shall not be more than 140°C (250°F), and the temperature recorded by any of the individual unexposed face thermocouples shall not be more that 180°C (325°F), during the following periods for each classification:

16. Report

16.1 Report all important information relevant to the test specimen and the fire test including the following specific items:

16.1.1 The name of the testing laboratory and the test date.
16.1.2 The name of the applicant for the test.
16.1.3 The name of the manufacturer of the test specimen and of the products and components used in the construction, together with identification marks and trade names.
16.1.4 The constructional details of the test specimen, including description and drawing and principal details of components. All the details of the specimen shall be give. The description and the drawings, which are included in the test report, shall, as far as practicable, be based on information derived from a survey of the test specimen.
16.1.5 All the properties of materials used that have a bearing on the fire performance of the test specimen together with measurements of thickness, density and, where applicable, the moisture or binder content, or both, of the insulation material(s) as determined by the test laboratory.
16.1.6 A statement that the test has been conducted in accordance with the requirements of these test methods (and if any deviations have been made to the prescribed procedures and a witness and their affiliation) and a clear statement of the deviations.
16.1.7 The name of the witness and their affiliation present at the test; when a test is not witnessed by a certifying authority, a note to this effect shall be made in the report.
16.1.8 Information concerning the location of all thermocouples fixed to the specimen, together with tabulated data obtained from each thermocouple during the test. Additionally a graphical depiction of the data obtained shall be included. A drawing shall be included which clearly illustrates the positions of the various thermocouples and identifies them relative to the temperature/time data.

16.1.9 The average and the maximum temperature rises, recorded at the end of the period of time appropriate to the insulation performance criteria for the relevant classification of insulation. If the test is terminated due to the insulation criteria having been exceeded, the times at which limiting temperatures were exceeded.

16.1.10 The individual unexposed thermocouple readings at each time interval. The average, as described in 14.1.2, and maximum thermocouple at each time interval.

16.1.11 The individual furnace thermocouple reading at each time interval. The average furnace thermocouple reading at each time interval.

16.1.12 Observations of significant behavior of the test specimen during the test and photographs or video recordings or both.

17. Precision and Bias

17.1 The precision and bias of these test methods have not yet been determined.

18. Keywords

18.1 bulkhead, deck; fire test response; hydrocarbon pool fire; restricted, unrestricted, insulation; temperature, heat flux
A1. TOTAL HEAT FLUX SENSOR ("CALORIMETER")

A1.1 General Description—For measurement of total heat flux, a water-cooled circular foil “Gardon Gage” heat flux sensor shall be used. A general description of this type of gage is given in Test Method E 511, which was developed by ASTM Subcommittee E21.08. While it is used to make total heat flux measurements, this device is designed for making radiative heat flux measurements. Caution must be exercised when using this gage to make measurements with a large convective fraction as a result of calibration constant changes. Additional information is contained in the literature (1-4). This rapid-response sensor derives its output from a differential thermocouple circuit that measures the temperature difference between the center and periphery of the active sensing area (which is the water-cooled circular foil). This millivolt area output is self-generating and is directly proportional to the total heat flux.

A1.2 Specifications:
A1.2.1 View Angle—180°.
A1.2.2 Accuracy—±3 % of reading (radiative fluxes only).
A1.2.3 Linearity—±2 % of full range.
A1.2.4 Repeatability—±1/2 %.
A1.2.5 Response Time—0.5 s or less.
A1.2.6 Surface Coating Absorptivity—To be specified by the manufacturer for a 2500°R (139K) blackbody radiation spectrum.

A1.3 Calibration:
A1.3.1 Each instrument shall have a certified calibration for the range of intended use, directly traceable to the National Institute for Standards and Technology (NIST). The instrument shall have a certified recalibration, for the range of intended use, directly traceable to the NIST range if intended use, directly traceable to the NIST whenever there is reason to suspect that recalibration is required (for example, if there is a change in the appearance of the sensor coating); or at least once per year, or after 25 testing hours, whichever comes first.
A1.3.2 Before each use, each instrument should have a recalibration performed by the testing laboratory that is either directly or indirectly traceable to NIST.

A1.4 Operation—Because condensation on the surface of the sensor can cause faulty readings, the temperature of the sensor shall be kept above 120°F (50°C) or above the dew point of the local environment, whichever is greater.

A1.5 Mounting and Use—Sensors shall be mounted in the calibration fixtures. The sensors shall be mounted where there is no direct flame or high-velocity jet impingement. The water-cooling must be capable of maintaining foil edge temperature less than 300°F (150°C).

A1.6 Acceptable Sensors—Several sensors have been verified by their manufacturers to meet the requirements of A1.1 through A1.2.

A1.7 Radiometers and Calibrations—Radiant heat flux measurements are not required in the test method. If radiant heat flux measurements are desired, radiometers based on the designs of the total heat flux sensors are available. If the radiometer uses a window, calibration of the sensors shall be performed with the window in place and use a thermal source with a radiation spectrum similar to that present in a furnace at 2500°R (139K).

APPENDIXES

X1. COMMENTARY

X1.1 Introduction—This commentary has been prepared to provide the user of these test methods with background information and rationale on the development of these test methods and the selected standard test condition. These test methods are primarily intended for evaluation of materials used for fire protection of structures in the hydrocarbon processing industry (HPI) (such as oil refineries, petrochemical plants, offshore oil-production platforms, and so forth), and other structures that can be exposed to large, free-burning, fluid hydrocarbon-fueled, pool fires. No attempt has been made to incorporate all the available information on pool fires in this commentary.

X1.2 Basic Differences in Large Pool Fire Test Versus Test Methods E 119—Before the development of these test methods, Test Methods E 119 were the only standardized tests available
for evaluation of the thermal response of structural members and assemblies to fires. These test methods differ from Test Methods E 119 in two major ways:

X1.2.1 When a furnace is used to produce the thermal exposure, the primary control for these test methods is based on a calibration procedure that develops a time-temperature curve to produce a specified heat flux incident upon the test specimen.

X1.2.2 These test methods get hotter faster than in Test Methods E 119, which consequently subjects the test specimens to a strong thermal shock. Specifically, these test methods specify a cold wall heat flux of 204 kW/m² (65 000 Btu/ft²-h) upon the test specimen within 5 min of test initiation. This compares to values measured in a major Test Methods E 119 furnace of 35 kW/m² (11 100 Btu/ft²-h) at 5 min and 18 kW/m² (37 400 Btu/ft²-h) at 60 min (5).

X1.2.3 Need to Control Heat Flux—The heat flux incident upon an object is defined as energy per unit area per unit time (for example, Btu/ft²-h (kW/m²)). During the initial stages of the fire, the thermal response of an object to the fire is a direct function of the heat flux to which the object is exposed (5-9). While temperature is an important driving force for heat flux, temperature alone does not sufficiently define a fire environment. For example, both a match and a large pool fire (for example, 50 ft in diameter) burn in a roughly similar temperature regime (from 871 to 1093°C (1600 to 2000°F)), but clearly a person can safely get within a few inches of a match. The reason is, that the size of the pool fire results in a much higher incident heat flux. Therefore, it is temperature as well as other factors, such as fire size, flame thickness, and so forth, that cause heat flux. One study of Test Methods E 119 concluded:

Exposure severity is given indirectly and incompletely by specification of the furnace temperature. The true measure of severity is given by the heat flux. Our overriding conclusion is to recommend that future improvements of Test Methods E 119 focus more on the control, measurement, and specification of the heat flux condition rather than the ambient gas temperature history (10).

Therefore, specifying a combination of the heat flux and the temperature for the control of these test methods represents an advance in fire technology, not a unique requirement for large pool fires as such.

X1.3 Need for a Large Hydrocarbon Pool Fire Test:

X1.3.1 A large pool fire is loosely defined as that resulting from hundreds (or thousands) of gallons of liquid hydrocarbon fuel burning over a large area (several hundred to several thousand square feet) with relatively unrestricted air flow to it and combustion products from it (for example, outdoors). A number of large pool fire experimentalists (11-18) have shown that high heat flux and temperature conditions are rapidly achieved in this fire (typically in less than 1 min.) This is in sharp contrast to the slow rate of buildup of thermal conditions in the Test Methods E 119 fire, which simulates a fire in which the fuel is solid and restrictions exist on air flow to (and combustion products from) the fire.

X1.3.2 The HPI facilities, which largely are located outdoors, handle large quantities of hydrocarbon fluids. Personnel responsible for safety and loss prevention in these facilities are concerned that when they have a fire of consequence, it is a large pool fire, not a Test Methods E 119 type fire, and that structures, assemblies, and fire protection materials should be designed based on ratings in a large pool fire, not the Test Methods E 119 fire (19-22). Indeed, Norway now specifies firewalls on offshore platforms rated per a hydrocarbon fire (23).

X1.3.3 The concern for materials and structural performance in large pool fires has led to the development of several different types of large pool fire simulation tests (5, 6, 20, 24-27) that have shown that materials can perform quite differently in Test Methods E 119 versus pool fire test. For example, one experimenter showed that 2 in. of a standard fireproofing material gave only 1 h in a pool fire simulation test versus a nominal 3-h Test Methods E 119 rating (20).

X1.3.4 However, the existence of various simulation tests has sometimes led to confusing and conflicting results, and the lack of a standardized test has inhibited acceptance of ratings in accordance with this test method (21). Therefore, the need was established for this standardized test method that simulates the effects of large pool fires on the types of structures and assemblies that are used in HPI facilities.

X1.4 Rationale for the Specific Test Conditions:

X1.4.1 Need for a Single Set of Test Conditions—To establish a standardized large pool fire simulation test, the issue becomes one of selection of the conditions to simulate. As demonstrated by the various large pool fire experimenters, a range of temperatures, velocities, heat fluxes, and chemical conditions exist, and they vary dramatically with time and spatial location (12, 14). From a pragmatic viewpoint, selection of multiple test conditions would probably result in prohibitively high testing costs. Therefore, it becomes a case of whether engineering judgment can be exercised in selecting a single set of test conditions that represent a reasonable worst case for HPI facility design purposes.

Note: X1.1—Reasonable worst case means, in essence, designing to withstand the most severe set of conditions that could be expected, within reason, to occur. Note that the design solution for a structure exposed to the reasonable worst case set of fire conditions selected does not necessarily have to be limited exclusively to passive fire protection, but can, and generally does, include a combination of passive plus active systems fixed and mobile.

X1.4.2 Radiant Heat Flux and the Continuous Total Flame Envolvement Criterion—There is a consensus that radiation is the dominant heat transfer mechanism to an object immersed in a large pool fire (6, 9, 11, 12, 14, 17). Radiant heat transfer to an object is defined by the Stefan-Boltzmann equation as follows:

\[
q = \sigma e FT^4
\]  

(X1.1)

where:

\( q \) = radiative heat flux incident on the exposed time, \( \text{kW/m}^2 \) (Btu/ft²-h);

\( \sigma \) = Stefan-Boltzmann constant, \( 5.67 \times 10^{-11} \text{kW/m}^2 \text{K}^4 \);
\[ \epsilon = \text{emissivity of the fire as viewed from the exposed item} \]
\[ F = \text{view factor of the exposed item to the fire (by definition} \]
\[ T = \text{absolute temperature of the fire, °R or K}. \]

Therefore, to determine a reasonable worst case radiation condition, consideration must be given to the view factor to the fire, fire emissivity, and time continuity, as well as fire temperature.

X1.4.2.1 View Factor—Only those surfaces of an object that are in a direct visual line to a fire can receive heat flux. Because an object located outside of, or on the periphery of, a fire has a view factor (to the fire) of 0.5 or less, it is clear that maximum radiation occurs when the object is fully engulfed in the fire and hence has a view factor of 1.0 (which is the theoretical maximum) and that this is a reasonable maximum.

X1.4.2.2 Emissivity of a Fire—By definition, emissivity ranges from zero (for example, no flames at all) to 1.0 (for example, flames so thick that they cannot be optically seen through). Experimenters are tending to believe that in a fire that has a large quantity of luminous soot particles (such as a liquid hydrocarbon fueled pool fire), flames only have to be 3 to 6 ft thick to be optically opaque (15). Clearly, then, it is a reasonable maximum to have an emissivity of 1.0.

X1.4.2.3 Time Continuity—This is perhaps the most important factor. Consider an example of fire exposure of an individual structural member, such as a beam or column, centered in a pool fire on the order of 30 to 40 ft in diameter. It is clear that, at least at some times during the fire, an optically opaque fire can totally engulf the beam or column. Hence it is reasonable for the view factor and fire emissivity to be 1.0 at some times, with respect to the beam or column. The question then must be answered: For what percentage of the time duration of the fire (for example, if it is a 1-h fire) do these conditions prevail? Since these pool fire predominantly occur outdoors, and since even small winds can cause the fires to fluctuate greatly in a given space (Note X1.2) (12, 15-18), this is a very difficult question to answer. Therefore, an assumption has to be made, and the reasonable worst case assumption made is that the total engulfment conditions prevail 100% of the duration of the fire exposure. In other words, total continuous engulfment means that at no time during the fire does any part of the structural member ever see out (nor would an imaginary observer anywhere outside of the fire ever see in to the member). Because the performance of any individual member (for example, a column) can be critical, this total continuous engulfment criterion designs the member as if it were in the central portion of a large stationary fuel spill on a relatively windless day for the duration of the protection time desired (for example, 1.0 h).

Note X1.2—Indeed, virtually all large pool fire experimenters specifically wait for windless (or special prevailing wind) conditions to conduct their fires so they have a measure of control on their experiment.

X1.4.3 Total Heat Flux:

X1.4.3.1 The specified total heat flux is 204 kW/m²·h (65 000 Btu/ft²·h²) within 5 min of fire initiation, and is a summation of the radiative plus convective components, with the radiative component being very dominant:

\[ q_r = q_c = q' \]

where:

\[ q_r = \text{total heat flux, kW/m}^2 \text{ or Btu/ft}^2\cdot\text{h}; \]
\[ q_c = \text{radiant heat flux, see Eq X1.1; and} \]
\[ q_c = \text{convective heat flux, } h(T_f - T_s) \text{ (see Eq X1.3)}. \]

Therefore, total heat flux is a strong function of fire temperature(s), and the convective component is a function of the temperature and velocity of the gases in the fire. In X1.4.4 and X1.4.5, fire temperature and gas velocity are discussed.

X1.4.3.2 Measurement of heat flux in a fire is a difficult experimental task. However, it is surprising how much agreement there is between experimenters, given this experimental difficulty plus the fluctuation of conditions within a given fire, as well as the differences in types and sizes of fires and where and how the heat flux measurements are made and other variables (for example, wind).

(1) Bader of Sandia (11) measured heat fluxes in large pool fires by several methods and developed a simplified computer model to predict the response of an object immersed in the fire. Using slug (that is, solid metal) calorimeters, the maximum time-integrated measured heat flux in 5.5- by 5.5-m (18- by 18-ft) fires was 150 kW/m² (47 500 Btu/ft²·h). For modeling of an object’s response, he states:

It was realized that both radiant and convective heat transfer played significant parts as energy transfer modes within a fire, but it was reasoned that at high temperature the radiant mode would be dominant, blackbody source temperature which would combine the effects of radiation and convection. A study of experimental temperature measurements was undertaken. After analyses, “It was decided that a good numerical representation of a large free-burning fire was possible using an 1850°F (1010°C) blackbody temperature as the input.”

Note X1.3—This input began at –1 min after fire initiation. Blackbody radiation at 1850°F (1010°C) gives a heat flux of 48 800 Btu/ft²·h (154 kW/m²).

(2) Canfield and Russell of the U.S. Navy (12) mapped the temperature and radiant heat flux (using Gardon gages) at up to 32 points in the flame plume of a 16- by 8-ft (4.9- by 2.4-m) pool fire. The maximum means value of radiant heat flux was 51 000 Btu/ft²·h (161 kW·m²), this being in the (spatially) small hot core of the flames (measured from 1945 to 1974°F (1063 to 1079°C).

(3) NASA and Avco (13) measured total heat flux in a 48- by 54-ft (14.6- by 16.5-m) pool fire using a Gardon gage. The maximum total heat flux measured was 50 600 Btu/ft²·h (160 kW/m²).

(4) Brown of the FAA (16) also used Gardon gages to measure total heat flux at one point in a series of 20- by 20-ft (6.1- by 6.1-m) pool fires under various wind conditions. The result: “The heat flux to the . . . calorimeters averaged about 50 400 Btu/ft²·h (159 kW/m²) for calm wind or steady perpendicular wind (blowing fire toward calorimeter) tests.” (The heat...
fluctuations was about 18,000 Btu/ft²·h (56.7 kW/m²) for wind blowing away. The heat flux reached quasisteady state values in less than 20 s.

(5) Mansfield of NASA (14) also used Gardon gages. The fires were 25 by 25 ft (7.6 by 7.6 m) and 30 by 80 ft (9.1 by 9.1 m). The average total heat flux of three points was 50,800 Btu/ft²·h.

(6) In a series of tests at Sandia National Laboratories (17, 18, 28), a variety of flat plate and cylindrical calorimeters have been used in 30- by 60-ft (9- by 18-m) pool fires to obtain hot wall heat fluxes to objects of different sizes and shapes. The maximum average value of the cold wall heat flux in these test methods was slightly less than 50000 Btu/ft²·h (158 kW/m²).

X1.4.3.3 Therefore, the selected value of 50,000 Btu/ft²·h (158 kW/m²) is a reasonable average of the experimental values. This is assumed to be a reasonable worst-case exposure.

X1.4.4 Convective Heat Flux and Gas Velocity:

X1.4.4.1 While the convective heat flux is not called out separately in these test methods, on a vertical column it is expected to be approximately 10% of the total heat flux or about 5000 Btu/ft²·h (16 kW/m²) (see X1.4.4.4).

X1.4.4.2 Convective heat flux to an object occurs as the result of the flow over the object of gases of higher temperature than the object. For an object of a given shape (for example, a 9-ft tall column), and gases of a given temperature and composition, the convective heat flux is a function of the velocity of the gases and their orientation to the object. In the continuous engulfment portion (see X1.4.2) of a large pool fire, the prevalent (time-wise at any one spatial point) velocity of the combustion gases is vertical as a result of the buoyant forces of the flame plume (for example, in comparison to any wind conditions that could exist which would add horizontal component to the gas velocity, and to very sporadic cyclone-type whirling vortices). For the example of a 9-ft (2.7-mm) tall column, the flow is parallel to the 9-ft height and is turbulent and the convective heat flux can be quantified as follows:

\[ q_c = h_{avg} (T_g - T_s) \]  
\[ h = 0.0037 \times (k/L) \times (V/Lv)^{0.8} \times Pr^{0.33} \]

where:

- \( q_c \) = cold wall convective heat flux, Btu/ft²·h; wall at 70°F;
- \( h_{avg} \) = average heat transfer coefficient, Btu/ft²·h · oF;
- \( T \) = average gas temperature, °F;
- \( L \) = height of the column, ft;
- \( k \) = thermal conductivity of the gases, Btu/ft²·h · °F;
- \( v \) = kinematic viscosity of the gases, ft²/h;
- \( Pr \) = Prandtl number; and
- \( V \) = average velocity of the gases, ft/h.

X1.4.4.3 Unfortunately, state-of-the-art heat transfer theory for buoyant plume velocities in large pool fires is corroboration. Theory (9, 29-33) states that maximum (vertical) velocity occurs at the centerline of a fire (under windless conditions), and increases with height (until a height is reached where lateral air entrainment/dilution effects cause the flame plume to become dissipated) (Note X1.3). Vertical velocity in general decreases with lateral distance from the fire centerline. Published data on velocity measurements is scarce. One published value of measured vertical plume velocity in a large pool fire is 38 ft/s (11.6 m/s) at a 20-ft (6.1-m) elevation at the exact centerline of a 50-ft (15.2-m) diameter fire (17). Reference (19) provides average velocities at the centerline of a 9 by 18 m, and 9.5 m/s at 6.1 m; velocities measured during periods of low winds are up to 30% higher. References (18, 29-33) provide theoretical analysis.

X1.4.4.4 Using Eq X1.3 and X1.4, and using \( T = 2000°F \) (1093°C) and estimated properties (that is \( k, v, Pr \)) for the combustion gases, \( q_c \) computes to slightly of 5000 Btu/ft² is total specified heat flux of 50,000 Btu/ft²·h (159 kW/m²). This agrees well with Mansfield’s observation (14). “This division of radiant and convective energy transfer is similar to a frequently accepted average or standard radiant/convective ratio of 9:1 for large pool fires.”

X1.4.4.5 Although theory predicts higher velocities at higher elevations, common HPI design practice limits the major areas of fire protection concern to a maximum of 30 to 40 ft (9.1 to 12.2 m) above the fire source (23). The 20-ft (6.1-m) height at which the 38-ft/s (11.6-m/s) value was reported (17) or the 41-ft/s (12.6-m/s) value reported in (18) during low winds are therefore at the approximate average height of HPI concern. Note that the data reported (18) show that the temperatures at this elevation are lower than at some elevations closer to the pool surface.

X1.4.4.6 As a counterpoint to the discussion of X1.4.4.4, the possibility exists that some fireproofing materials might be susceptible to erosive damage because of exposure to high-temperature gases with velocities representative of those measured in large pool fires. However, preliminary analysis of measurements made in large pool fires at Sandia National Laboratories, gives a shear stress estimate of less than 1 psf (50 Pa). As technology advances, this entire subject of gas velocity and its effects is one that could use further attention.

X1.4.4.7 As a pragmatic point, it is extremely difficult and expensive experimentally to generate high velocities of large quantities of hot gases and direct them in a highly controlled manner on a large test specimen. In fact, it is not clear if any existing test facility, other than an actual fire, has the capability of generating the representative velocities.

X1.4.5 Fire Temperature:

X1.4.5.1 The specified fire temperature (that is, the temperature of the environment that generates the heat fluxes of X1.4.3 and X1.4.4) is from 1850 to 2150°F (1010 to 1180°C). While this range is narrower than that seen in large pool fires (15, 17, 18), it was selected for two reasons:

(1) As the discussion in X1.4.5 presents, fires do not burn at any one temperature, but rather consist of gases with a wide range of temperatures, depending on spatial and time position in the fire. The range from 1700 to 2300°F (927 to 1260°C) is typical of the luminous plume engulfment region of large pool fires (12, 15, 17, 18). The selected range is in the middle of the broader range.

(2) The selected temperature range provides the experimenter/test facility with some flexibility and latitude in the means used to achieve the specified heat fluxes.

X1.4.5.2 As a reference point, using Eq X1.1 (the Stefan-Boltzmann equation for radiant energy transfer), if one is
disposed to think of the fire at a single idealized temperature, then for the blackbody radiation case of emissivity \(-1\) and view factor of \(F = 1\), \(T_f = 2000^\circ\text{F} (1093^\circ\text{C})\) gives an incident radiant heat flux of 63 770 Btu/ft\(^2\)-h (198 kW/m\(^2\)). Indeed, this concept of a single fire temperature is quite useful if an enclosed furnace is used as the test simulation facility. The heat flux of 65 000 Btu/ft\(^2\)-h called out in this test method would require a surface absorptivity of 0.8.

**X1.4.5.3** Temperature can be thought of as the driving potential for the heat flux. In actuality, the temperature in a luminous mass of combusting gases from a pool fire is not a constant but varies over a wide range, from about 1000 to 1200°F (538 to 649°C) at the air-entraining edge of the plume to a broad internal zone from 1200 to 1900°F (649 to 1038°C) to a small central hot core from about 1900 to 2200°F (1038 to 1204°C) (12, 15). One set of data for a spatially fixed grid of up to 50 thermocouples in the vertical cylindrical space over a 50-ft (15.2-m) diameter pool fire on a windless day gave the following time-averaged volumetric distribution (31):

<table>
<thead>
<tr>
<th>Temperature Range</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 1200°F (649°C)</td>
<td>66 %</td>
</tr>
<tr>
<td>1200 to 1900°F (649 to 1038°C)</td>
<td>23 %</td>
</tr>
<tr>
<td>1900 to 2200°F (1038 to 1204°C)</td>
<td>11 %</td>
</tr>
</tbody>
</table>

Given the fluctuating nature of a pool fire, and therefore the probability that at some times the member will see out through the fire, thus counterbalancing exposures to higher temperatures, the specified range appears to meet the criterion of a reasonable worst case.

**X1.4.6 Gas Chemistry and Oxygen Content:**

**X1.4.6.1** While the chemistry of the gases adjacent to the test specimen are not specified in these test methods, some discussion of these topics was considered appropriate for commentary.

**X1.4.6.2** The chemistry in the fire plume of a pool fire is, like temperature, not a constant, but dynamic with time and spatial position. On the one hand, the chemistry is complex such as CO, CO\(_2\), HO, O, N, H, and C\(_n\)H\(_m\) (for example, various hydrocarbons), soot particles, and so forth. On the other hand, the chemistry is relatively straightforward—that of a fluid hydrocarbon reacting with air. Therefore, the range of chemical species present are relatively well known.

**X1.4.6.3** The most extensive measurement of chemistry in a pool fire is given by Ref (15), where up to 23 spatial points were sampled periodically in the cylindrical area over a 50-ft (15.2-m) diameter pool fire. One analysis of this data led to the statement: “The overall conclusion form the data presented is that in the JP-4 fuel fire there is very little oxygen at the center of the fire up to a height of 1.5 fire radius. That is, combustion is still taking place” (30). For the 50-ft diameter fire cited, a height of 1.5 fire radius is about 38 ft (11.6 m), approximately the normal maximum height of primary interest for fire protection (in accordance with the HPI; see X1.4.4.4).

### X2. USE OF FURNACE TYPE FACILITIES

**X2.1** While these test methods do not restrict the technique used to achieve the test conditions specified in Section 6 for the purposes stated in Section 1, there is strong interest in the use of traditional fire test facilities. The use of enclosed furnaces to simulate the thermal effects of a hydrocarbon fire is discussed.

**X2.2** Traditionally, enclosed furnace-type facilities have been used for testing of structural response of materials (for example, for Test Methods E 119 testing). These furnaces normally are fueled by a clean burning gas such as natural gas or propane. Experimental experience to date indicates that gas-fired enclosed furnaces are in concept also usable to simulate the pool fire conditions specified in Section 6 for the purposes specified in Section 1. The reason that an enclosed furnace type facility appears applicable to simulating the pool fire can be understood by referring to the discussion in X1.4.2, which explained that the 50 000-Btu/ft\(^2\)-h heat flux condition simulates total engulfment in the luminous portion of the flame plume. That is, the view factor \(F\) and emissivity are at the maximum value of 1.0. In addition, the fire is conceptualized as being at a uniform temperature of 1865°F (1018°C), as explained in X1.4.5.2. Consider a 2.7-m (9-ft) column in an enclosed furnace with optically opaque walls at 1865°F (1018°C) and with optically transparent gases in the furnace also at 1865°F (1018°C). The view factor of the column to the walls of the furnace is 1.0. If the walls of the furnace and the surface of the column are at a uniform temperature, the effective emissivity of the walls is 1.0 (Note Note X2.1). The radiant heat flux to the specimen in accordance with Eq X1.1 is the specified 65 000 Btu/ft\(^2\)-h. As long as the temperatures are uniform throughout the furnace, the same discussion for radiant heat fluxes holds true even if the gases in the furnace are not transparent.

**NOTE X2.1—**For the case of a fully enclosed furnace with optically opaque walls and at a uniform temperature, the radiosity (that is, the sum of the emitted and reflected radiation) of the walls is constant and equal to that of a blackbody at the same temperature, regardless of the materials of construction of the furnace (34). The walls have an effective emissivity of 1.0, regardless of the actual emissivity of the wall material. If the test specimen is at a temperature lower than that of the furnace walls, the heat flux to the specimen will drop below the blackbody flux based on the wall temperature. The size of the effect depends on the size of the test specimen relative to the furnace volume, the temperature difference, and the radiative properties of the test specimen and the furnace materials (35).

Standard Specification for
Sound-Absorbing Board, Fibrous Glass, Perforated Fibrous Glass Cloth Faced

This standard is issued under the fixed designation F 2154; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This specification covers fibrous glass sound-absorbing board with a perforated fibrous glass cloth facing for sound reduction in ship spaces with high noise levels. This specification is primarily for materials used on ships. Additional requirements, testing, and certification are required for use of this material aboard U.S. Coast Guard inspected vessels in the United States.

1.2 This standard measures and describes the response of materials, products, or assemblies to heat and flame under controlled conditions, but does not by itself incorporate all factors required for fire hazard or fire risk assessment of materials, products, or assemblies under actual fire conditions.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.

2. Referenced Documents

   E 84 Test Method for Surface Burning Characteristics of Building Materials\(^4\)

2.2 ANSI Standard:
   ANSI/ASQC Z1.4 Sampling Procedures and Tables for Inspection by Attributes\(^5\)

2.3 Other Documents:
   46 CFR 164.012 Code of Federal Regulations—Interior Finishes for Merchant Vessels\(^6\)
   Navigation and Vessel Inspection Circular (NVIC) 9-97\(^7\)

3. Terminology
3.1 For definitions of terms used in this specification, see Terminology C 634.

4. Ordering Information
4.1 Title, number, and date of this specification.
4.2 First article sample, when required (see 7.1).
4.3 Width and length required, if other than 24- by 36-in. (609.6- by 914.4-mm) board (see 8.1).
4.4 Thickness required (see 8.2).
4.5 Density of waffle board (see 10.1).
4.6 Conformance inspection reports required (see 11.1).

5. Materials and Manufacture
5.1 See typical construction details located in Supplementary Requirements Section S3.

6. Performance Requirements
6.1 Surface Flame Spread and Smoke Generation Properties—The sound-absorbing board shall meet the requirements for surface flame spread and smoke generation properties for an U.S. Coast Guard Approved Interior Finish in accordance with 46 CFR 164.012 or NVIC Circular 9-97.

6.2 Facing Separation—When the sound-absorbing board is cut or sawed, the threads of the fibrous glass cloth facing across which the cut is made shall not be separated from the face over a distance of more than 3.0 mm (¼ in.). In case the fibrous glass cloth facing does not cover the entire surface of the board, the uncovered portion of the board shall not extend further than 3.175 mm (¼ in.) from any edge. The fibrous glass cloth facing shall not extend over the edge of the board.

---

\(^*\) This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.02 on Insulation/Processes.

\(^3\) Annual Book of ASTM Standards, Vol 04.07.

\(^4\) Available from American National Standards Institute, 25W. 3rd St., 4th Floor, New York, NY 10036.

\(^6\) Available from Superintendent of Documents, P.O. Box 371954, Pittsburgh, PA 15250–7954.
6.3 Sound-Absorption—When tested as specified in 10.3, the sound-absorbing board shall have coefficients of absorption that are equal to or greater than those shown in Table 1.

7. Other Requirements

7.1 First Article—When specified (see Section 4), the contractor shall furnish sample unit(s) for first article inspection and approval (see 11.1).

8. Dimensions and Tolerances

8.1 Width and Length—Unless otherwise specified (see Section 4), the sound-absorbing board shall be furnished in a width of 609.6 mm (24 in.) and a length of 914.4 mm (36 in.) (see 11.2).

8.2 Thickness—The sound-absorbing board shall be furnished in thicknesses of 25.4 mm (1 in.) or 50.8 mm (2 in.), as specified (see Section 4 and 11.2).

8.3 Tolerances—Tolerances on length and width shall not exceed ±6.35 mm (¼ in.). Tolerance on thickness shall not exceed ±2.38 mm (⅜ in.) –0 mm (0 in.).

9. Sampling

9.1 Inspection Lot—For the purpose of sampling, a lot shall consist of all boards of the same thickness produced under essentially the same conditions, and offered for delivery at one time.

9.2 Sampling for Visual and Dimensional Examination—A random sample of board shall be selected from each lot offered for inspection in accordance with ANSI Z1.4 at Inspection Level II. No defects shall be allowed.

9.3 Conformance Test Sampling—When density and surface flame spread and smoke generation property tests are required in accordance with 11.1.2, the samples shall be selected in accordance with 9.3.1 and 9.3.2.

9.3.1 Sampling for Density Test—Sample boards shall be selected in accordance with ANSI Z1.4 at Inspection Level S-4 for the density test of 10.1. No defects shall be allowed.

9.3.2 Sampling for Surface Flame Spread and Smoke Generation Properties—A sufficient number of boards shall be randomly selected and joined end-to-end to form a specimen 50.8 cm (20 in.) wide by 50.8 mm (2 in.) thick by 731.5 cm (24 ft) long. The specimen shall be subject to the surface flame spread and smoke generation property test of 10.2.

10. Test Methods

10.1 Density—The density of the waffle board fibrous glass layer (see S3.1.2) shall be tested at the location of manufacture prior to fabrication into final form panels. Density is determined by dividing sample mass by sample volume. Sample mass is measured to the nearest 1.0 g and sample volume is measured to the nearest 1 cm³ of water displaced by one standard board as specified (see 9.3.1).

10.2 Surface Flame Spread and Smoke Generation Properties—The test specimens (see 9.3.2) shall be tested in accordance with Test Method E 84 (see S5).

10.3 Sound Absorption Coefficients—The sound-absorbing board shall be laid directly on the floor of a reverberation room and tested in accordance with Test Method C 423.

11. Inspection

11.1 Type approvals for 46 CFR 164.012 include inspection requirements as part of the specific type approval.

12. Packaging

12.1 Commercial Packaging—Commercial packaging shall be in accordance with Practice D 3951.

13. Keywords

13.1 fibrous glass cloth; perforated fibrous glass cloth; reverberation room method; sound absorbing; sound absorption coefficient; sound reduction; surface flame spread and smoke generation properties; waffle board

SUPPLEMENTARY REQUIREMENTS

(Mandatory Information for U.S. Navy)

This specification is adapted from MIL-A-23054.

S1. Supplemental Requirements and Exceptions to the Requirements of This Specification for Ships of the U.S. Navy

S1.1 DoD Intended Use—The sound-absorbing board covered by this specification is intended for reduction of sound in spaces where there is a high level of noise.
S2. Referenced Documents

S2.1 Military Specifications:
- MIL-I-742 Insulation Board, Thermal, Fibrous Glass
- MIL-A-3316 Adhesives, Fire-Resistant, Thermal Insulation
- MIL-C-20079 Cloth, Glass; Tape, Textile, Glass; and Thread, Glass

S3. Materials and Manufacture

S3.1 Material—The sound-absorbing board shall be a laminate consisting of a perforated fibrous glass cloth facing, a high-density fibrous glass layer waffle board, and a fibrous glass backing board. Asbestos fibers and components containing asbestos fibers are prohibited.

S3.1.1 Backing Board—The backing board shall conform to Type II of MIL-I-742 unfaced board except that the board shall be furnished in nominal thickness of 19.05 mm (3/4 in.) or 44.45 mm (1 3/4 in.) (see 5.1.2 and 8.2).

S3.1.2 High-Density Fibrous Glass Layer—The fibrous glass layer shall have a density of not less than 160 kg/m³ (10 lb/ft³) (see 10.1). The layer shall consist of glass fibers impregnated with a suitable binder and compressed or otherwise formed into a waffle. The nominal thickness of the high-density fibrous glass layer shall be 6.35 mm (1/4 in.).

S3.1.2.1 Waffle—The waffle shall be constructed having 4.76–mm (3/16-in.) deep indentations tapering from a nominal 6.0–mm (1/4-in.) diameter to a nominal 3.175–mm (5/32-in.) diameter indentations on a 12.7–mm (1/2-in.) center.

S3.1.3 Fibrous Glass Cloth Facing—The cloth used for facing the high-density fibrous glass layer shall conform to Type I, Class 2 of MIL-C-20079. The cloth facing shall be impregnated with a hardening agent. The cloth facing shall be perforated with nominal 4.76–mm (3/16-in.) diameter holes on a 12.7-mm (1/2-in.) center.

S3.1.3.1 Facing Adhesive—The impregnated fibrous glass cloth facing shall be compatible with adhesive conforming to Type II of MIL-A-3316. The adhesive strength requirements for securing fibrous glass cloth facing to the high-density fibrous glass layer shall conform to MIL-A-3316.

S3.2 Recycled, Recovered, or Environmentally Preferable Materials—Recycled, recovered, or environmentally preferable materials should be used to the maximum extent possible provided that the material meets or exceeds the operational and maintenance requirements, and promotes economically advantageous life cycle costs.

S3.3 Construction—One side of the high-density fibrous glass layer shall be adhered to the backing board and the other side adhered to the fibrous glass cloth facing, using adhesive. The fibrous glass cloth facing shall be free of wrinkles or other irregularities. The sound-absorbing board shall be so designed that the perforations in the fibrous glass cloth facing shall be centered over the indentations in the waffle-type high-density fibrous glass layer.

S4. Department of Defense Packaging

S4.1 DoD Packaging—For acquisition purposes, the packaging requirements shall be as specified in the contract or order. When actual packaging of material is to be performed by DoD personnel, these personnel need to contact the responsible packaging activity to ascertain requisite packaging requirements. Packaging requirements are maintained by the Inventory Control Point’s packaging activity within the Military Department or Defense Agency, or within the Military Department’s System Command. Packaging data retrieval is available from the managing Military Department’s or Defense Agency’s automated packaging files, CD-ROM products, or by contacting the responsible contracting activity.

S5. Performance Requirements

S5.1 Surface Flame Spread and Smoke Generation Properties—The sound-absorbing board shall have a flame spread index less than 30 and smoke development less than 100 when tested as specified in 10.2.

S6. Inspection

S6.1 Classification of Inspections—The inspection requirements specified herein are classified as follows: (1) first article inspection (see 11.1.1), and (2) conformance inspection (see 11.1.2).

S6.1.1 First Article Inspection—The first article inspection shall consist of the examination and tests shown in Table S6.1.

S6.1.2 Conformance Inspection—Conformance inspection shall consist of the visual and dimensional examination of S6.2. The density test of 10.1 shall be tested on each lot of material. New tests for density (10.1) and fire resistance (10.2) are required whenever the manufacturing methods or component materials are changed and reports supplied when requested.

S6.1.3 Examination—Each of the boards selected in accordance with 9.2 shall be examined to verify compliance with the dimensional requirements of this specification. When measuring length, width, or thickness, any convenient measuring rule graduated to 1.59 mm (1/16-in.) shall be used. Any board in the sample containing one or more defects shall be rejected. If the sample contains 3% or more of defective boards, the entire lot represented by the sample shall be rejected. The facing separation and workmanship examinations shall be included.

S6.1.4 Workmanship—The insulation shall be free of visual defects that will adversely affect the service quality. For example, holes or delamination of the facing when occurring to an excessive degree shall be judged to adversely affect the service quality of the material.

Standard Specification for
Packing Material, Graphitic, Corrugated Ribbon or Textured
Tape, and Die-Formed Ring

This standard is issued under the fixed designation F 2168; the number immediately following the designation indicates the year of
original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A
superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 Scope—This specification covers various types, classes,
and grades of flexible graphite material in which valve media
temperatures are limited to a maximum of 1050°F (966°C).
Where this specification is invoked as ASTM F 2168, Sections
1-18 apply. Where this specification is invoked as ASTM/DoD
F 2168, Sections 1-18 and the Supplementary Requirements
are applicable.

1.2 The values stated in SI units are to be regarded as
standard.

2. Referenced Documents

2.1 ASTM Standards:
- C 559 Test Method for Bulk Density by Physical Measure-
ments of Manufactured Carbon and Graphite Articles
- C 561 Test Method for Ash in a Graphite Sample
- C 816 Test Method for Sulfur in Graphite by Combustion-
Iodometric Titration Method

Combustion Methods

3. Terminology

3.1 Definitions:
- accordion crease, n—because of the method of con-
struction of die-formed rings, an accordion-like linear indica-
tion (crease) may appear singularly or in multiple locations
around the inside and outside diameter surface.
- corrosion inhibitors, n—additives to the products to
function in a passive or sacrificial manner to reduce galvanic
corrosion. These additives are typically embedded zinc pow-
der, phosphorus, or barium molybdate.
- corrugated ribbon, n—graphite ribbon or tape that is
subjected to mechanical pressure in a consistent manner to
apply surface indentations to the tape or ribbon.
- density, n—the mass per unit volume at a specified
temperature.
- detrimental materials, n—abrasive or chemically ac-
tive constituents such as ash particles (in high ash content foils)
or elemental materials that can cause galvanic action or
corrosion in long-term storage or service environments.
- die-formed ring, n—a packing ring made by mechani-
cally compacting winds of graphite ribbon or braided packing
in a die or fixture.
- lot, n—all finished packing of one size, type, class,
and grade produced in a continuous run or at the same time
under essentially the same conditions.
- set, n—the packing components required to pack one
valve.
- size, n—refers to the physical dimensions of the
packing material.

4. Classification

4.1 Classification—The material shall be of the following
types, classes, and grades as specified (see Section 5).

4.1.1 Type I—Corrugated ribbon or textured tape.

---

1 This specification is under the jurisdiction of ASTM Committee F25 on Ships
and Marine Technology and is the direct responsibility of Subcommittee F25.02 on
Insulation Systems.
3 Annual Book of ASTM Standards, Vol 15.01.
5 Annual Book of ASTM Standards, Vol 10.03.
7 Annual Book of ASTM Standards, Vol 05.06.
4.1.2 Type II—Die-formed ring.
4.1.3 Class I—For use where detrimental material content of the packing need not be controlled beyond normal manufacturing limit (commercial grade).
4.1.4 Class 2—For use where detrimental material content must be controlled to the limits specified herein.
4.1.5 Grade A—Treated with corrosion inhibitor.
4.1.6 Grade B—No corrosion inhibitor.

5. Ordering Information
5.1 Contracts or orders for the units under this specification shall include the following information:
5.1.1 Title, number, and date of this specification.
5.1.2 Type, class, and grade.
5.1.3 Type of corrosion inhibitor (see 6.1.3 and Supplementary Requirements).
5.1.4 Specify density of die-formed rings.
5.1.5 Inspection, testing, and certification of the material should be agreed upon between the purchaser and the supplier as part of the purchase contract (see Sections 14 and 16).
5.1.6 When die-formed (Type II) packing rings are desired, the ring height, inside diameter, outside diameter, number of cuts, and number of packing rings required per set (see 9.2 and 9.3).
5.1.7 Marking requirements (see Section 17 and Supplementary Requirements).
5.1.8 Packaging requirements (see Section 18 and Supplementary Requirements).
5.1.9 Application data (to include operating pressure, operating temperature, and media).
5.1.10 Specify thickness of Type I.

6. Materials and Manufacture
6.1 Material—Requirements specified herein apply to Class 1 and Class 2 and Grade A and Grade B packing, except where noted.
6.1.1 Type I—The packing shall be made entirely of flexible graphitic material having no binders and meeting the requirements of Tables 1 and 2.
6.1.2 Type II—Die-formed packing rings shall be manufactured from flexible graphitic material conforming to the requirements of Tables 1 and 2.
6.1.3 Coating and Corrosion-Inhibiting Treatments:
6.1.3.1 Grade A—Grade A packing shall be provided with a powdered zinc active corrosion-inhibiting treatment or a passive inhibiting treatment such as phosphorous or barium molybdate, as specified (see Section 5). If the use of inhibitors is required, both passive and active inhibitors shall be permitted to be used.
6.1.3.2 Grade B—Grade B packing shall not contain corrosion-inhibiting additives.

6.1.4 Mercury Exclusion—During manufacturing, fabrication, handling, packaging, and packing, the packing material shall not come in contact with mercury or mercury containing compounds.

7. Properties
7.1 Chemical and Physical Properties—Unless otherwise specified, the properties of the finished packing shall conform to the requirements of Table 1. Class 2 also requires compliance with Table 2.
7.2 Prohibited Additions—There shall be no intentional additions of any of the detrimental materials of Table 2 or antimony (Sb), arsenic (As), bismuth (Bi), cadmium (Cd), gallium (Ga), indium (In), lead (Pb), mercury (Hg), silver (Ag), or tin (Sn) during the manufacturing, fabrication, handling, packaging, and packing of the product.

8. Other Requirements
8.1 No other requirements noted.

9.1 Type I Ribbon Packing—Unless otherwise specified (see Section 5), the packing shall be uniformly coiled, spooled, or reeled in accordance with Table 3.
9.2 Type II Die-Formed Packing—Unless otherwise specified (see Section 5), the tolerances for Type II packing shall be in accordance with Table 4. The tolerance applies to finished rings before any cutting operations.
9.3 Split Rings—The number of cuts (zero, one, or two) shall be as specified (see Section 5). Cuts shall be made at approximately a 45° angle such that an overlapping joint is formed in the compressed state. When two cuts are required (separating the ring into two parts), the resulting parts shall be approximately the same dimension. If the number of cuts is not specified, single-cut rings shall be provided.

10. Workmanship, Finish and Appearance
10.1 Workmanship—The packing shall be free from extraneous material and visual defects that may affect its serviceability, as defined in Table 5.

13. Test Methods

13.1 Tests—In the event tests are required as part of the purchasing requirements (see 5.1.5), tests shall be made in accordance with the following tests or by way of alternate methods of analysis with equal to or improved accuracy and precision. The use of an alternate analytical method requires prior written consent of the purchasing party before acceptance will be allowed. Except for the corrosion-inhibiting treatment exceptions of 13.3 and 13.4, all testing shall be performed on final product after completion of all processing, including application of any binders and, if required, corrosion inhibitors.

13.2 Size—The size shall be determined by measuring each sample selected for visual examination (see Table 4).

13.3 Ash Content—The ash content shall be determined in accordance with Test Method C 561 (see Table 1). For Grade A packing only, the test shall be conducted before the corrosion-inhibiting treatment or the added mass of the corrosion inhibitor shall be determined and subtracted from the base mass of the sample.

13.4 Graphite Purity—The sample shall be dried to a constant mass at 300 ± 5°F (149 ± 3°C) before testing. For Grade A packing only, the test shall be conducted before the corrosion-inhibiting treatment or the added mass of the corrosion inhibitor shall be determined and subtracted from the base mass of the sample. The percent carbon shall be based upon mass of the dried sample. This determination shall be made in accordance with Test Methods D 3178 or an alternate method of analysis with equal or improved accuracy and precision (see Table 1).

13.5 Bulk Density—The bulk density of the Type I and Type II materials shall be determined in accordance with Test Method C 559.

13.6 Detrimental Material Tests—For determination of the detrimental materials listed in Table 2 for Class 2 only, the test methods of Table 6 or alternate methods of equal or improved accuracy and precision shall be used.

14.1 Inspection and testing of the material should be agreed upon between the purchaser and the supplier as part of the purchase contract (see 5.1.5).

15. Rejection

15.1 Materials that fail to conform to the requirements of this specification shall be rejected. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of testing, the producer shall make claim for a rehearing or provide for third party testing.

16. Certification

16.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been tested and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

16.2 Detrimental Materials Control—For Class 2 material only, the vendor shall provide certification that the limits of Table 2 have been met and that low melting metals (Sh, As, Bi, Cd, Pb, Sn, Ga, In, Ag, Hg and Zn [Zn for Grade B only]) have not been added as intentional constituents. In lieu of specific test results for the lot to be delivered, certifications shall be based on tests of both raw materials and production lots of similar finished packing material over an extended time period (not exceeding three years between tests). Any change to manufacturing processing that affects product composition, including changes to raw material, binders, or inhibitors (Grade A) shall require additional testing to form the basis for future certifications.

17. Product Marking

17.1 Marking—For commercial shipment, marking shall be in accordance with accepted industry practices or as required in the purchase contract (see 5.1.1). Marking shall include type of corrosion inhibitor, if any.

18. Packaging

18.1 Commercial Packaging—Commercial packaging shall be in accordance with Practice D 3951 or as required in the purchase contract (see 5.1.1).

19. Keywords

19.1 flexible graphite material; packing material

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract or order. All of these supplementary requirements, and Sections 1-18, are applicable where this specification is invoked as ASTM/DoD F 2168. This specification is adapted from MIL-P-24503.

S1. Scope

S1.1 DoD Intended Use—Packing is intended for general shipboard service in valves with the exception of potable water. Grade A packing is intended for use in valves with noncorrosion-resistant (for example, carbon steel, 400 series stainless steel) stem and packing gland parts.

S1.1.1 Type I—Type I packing is in corrugated ribbon or textured tape form for use where packing gland dimensions are not uniform or known. Type I packing may be used to manufacture Type II packing locally.

S1.1.2 Type II—Because Type II packing is die formed, it is designed for applications in new equipment or equipment in which packing gland dimensions are uniform or known and in excellent mechanical condition. The die-molded ribbon packing requires only a drop-in, but not loose, clearance with final gland compression setting the rings for proper operation.

S1.1.3 Class 1—Class 1 is intended for use where detrimental materials content of the packing need not be controlled beyond normal manufacturing limits.

S1.1.4 Class 2—Class 2 is intended for use where detrimental materials content must be kept to a minimum.

S2. Classification

S2.1 The type and class classifications of this specification correspond to the type and class classifications of MIL-P-24503.

S2.2 The Grade B classification of this specification corresponds to the Grade N classification of MIL-P-24503.

S2.3 The Grade A classification of this specification, using zinc powder corrosion inhibitor only, corresponds to the Grade I classification of MIL-P-24503.

S3. Materials and Manufacture

S3.1 Density Requirements:

S3.1.1 Type I—Unless otherwise specified (see Section 5), density of corrugated ribbon/textured tape shall be 65 ± 10 lb/ft³ (1040 ± 160 kg/m³).

S3.1.2 Type II—Unless otherwise specified (see Section 5), density of finished die-formed rings shall be 90 ± 10 lb/ft³ (1440 ± 80 kg/m³).

S3.2 Coating and Corrosion-Inhibiting Treatments:

S3.2.1 Grade A—Grade A packing shall be provided with a powdered zinc active corrosion-inhibiting treatment (2% Zn by weight, minimum) only.

S3.2.2 Grade B—Grade B packing shall not contain corrosion-inhibiting additives.

S4. Dimensions and Tolerances

S4.1 Type I—Unless otherwise specified, (see Section 5), thickness of Type I packing shall be nominal 0.015 in. (0.38 mm).
S5. Quality Assurance

S5.1 As a minimum, manufacturers shall provide and maintain an inspection system that meets the requirements of ANSI/ASQC Q9003\(^9\).

S6. Test Methods

S6.1 Examination for Visual and Dimensional Defects—Each unit selected for visual and dimensional examination shall be surface examined and measured to determine conformance with the requirements that do not require tests (see Section 10, including Table 5, and 13.2, including Table 6).

S6.2 Examination for Preparation for Delivery—Each unit selected shall be visually examined to determine compliance with packaging requirements (see Section 5 and 9.1) and marking requirements (see Section 5 and 9.9).

S6.3 Simulated Performance—The test shall be conducted in an apparatus designed to simulate conditions in valves in actual service. A schematic of the test rig is shown in Fig. S6.1. The valves used in the simulator shall have glands and stems that are in as new condition. The entire piping system and valves shall be insulated so as to minimize heat loss. Thermocouples shall be installed so as to indicate the actual steam temperature. The simulator shall be capable of holding a temperature of 975 ± 25°F (524 ± 14°C) and a pressure of 1200 ± 50 lb/in.\(^2\) (84 ± 3.5 kg/cm\(^2\)) for the duration of the test. The packing shall be installed and the gland initially adjusted so that no leakage occurs with the system at its operating temperature and pressure. While pressurized, the valve shall be fully cycled manually not less than once every half hour (full close to full open). The following schedule shall be followed for running the test (test need not be conducted over a weekend period, if desired):

- 12 days ± 1 day at temperature 975 ± 25°F (524 ± 14°C) and 1200 ± 50 lb/in.\(^2\) (84 ± 3.5 kg/cm\(^2\)) pressure
- 35 days ± 5 days at ambient temperature and pressure (system shut down; valves need not be cycled)
- 5 days ± 1 day at temperature 975 ± 25°F (524 ± 14°C) and 1200 ± 50 lb/in.\(^2\) (84 ± 3.5 kg/cm\(^2\)) pressure

There shall be no steam leakage from the packing gland during the simulated performance test at a temperature 975 ± 25°F (524 ± 14°C) and 1200 ± 50 lb/in.\(^2\) (84 ± 3.5 kg/cm\(^2\)) pressure. There shall also be no corrosion or degradation of the packing gland at the completion of the test. Any leakage or gland adjustment shall be recorded. This test is equivalent to the simulated performance test of MIL-P-24503.

S7. Inspection and Testing

S7.1 Unless otherwise specified (see Section 5), first-article testing and quality conformance testing are required. The inspections and tests making up the first-article and quality conformance testing are as follows:

S7.2 Sampling for First-Article Testing—A sample shall be subjected to the first-article testing of Table S7.1.

S7.3 Sampling for Quality Conformance Testing:

S7.3.1 Sampling for Visual and Dimensional Examination—As a minimum, the contractor shall randomly select a quantity of sampling units from each lot in accordance with Table S7.2 and subject them to the examination for visual and dimensional defects of S6.1. The sample size depends on the lot size. If one or more defects are found in any sample, the entire lot shall be rejected. The contractor has the option of screening 100% of the rejected lot for the defected characteristics or providing a new lot, which shall be inspected in accordance with the sampling plan herein. The contractor shall maintain for a period of three years after contract completion, records of inspections, tests, and any resulting rejections.

S7.3.2 Sampling for Chemical and Physical Property and Detrimental Materials Tests—A single random sample shall be selected from each lot for the testing of 13.3-13.6.

S7.3.3 Sampling for Examination for Preparation for Delivery—The lot size is the number of shipping containers. Sampling shall be in accordance with Table S7.2.

S8. Certification

S8.1 Simulated Performance Test—After the simulated performance test is once performed acceptably, providing product composition or processing has not changed, a certificate of compliance, citing the test report or document accepting compliance with the test requirement, may be provided thereafter.

S9. Product Marking

S9.1 Item description marking shall include, as a minimum, the size, class, grade, and type of inhibitor (if any) of the graphitic packing material. In addition, the item description marking shall include the phrase “ASTM/DoD F 2168” to identify the applicability of this specification and any special marking which shall be required, such as bar coding (see Section 5).

\(^9\) Available from the American National Standards Institute, 25 W. 43rd St., 4th Floor, New York, NY 10036.
S10. Rejection

S10.1 Known Defects—Materials that fail to conform to the requirements of this specification shall not be offered for delivery.

S10.2 Buyer Testing—The buyer reserves the right to perform any of the inspections and tests set forth in this document. Materials that fail to conform to the requirements of this specification shall be rejected. Rejection will be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of testing, the producer may make claim for a rehearing or provide for third party testing.

S10.3 Replacement of Test Specimens—A test specimen shall be discarded and a replacement specimen selected from the same lot of material under the following conditions:

S10.3.1 Where the specimen is incorrectly prepared,
S10.3.2 Where the test procedure is incorrect,
S10.3.3 Where there is a malfunction of the testing equipment, and
S10.3.4 Where a flaw that is not indicative of an inferior or defective lot of material develops during the test.

S10.4 Retests—Retests are only permitted for ash content, graphite purity, bulk density, and detrimental material tests. Retests shall be performed on twice the number of specimens that were originally nonconforming. Retest specimens shall be taken in the vicinity of the initial location of a failed specimen. If any of the retest specimens fail, the lot shall be rejected with no further retesting permitted.

S10.5 Resubmittal of Rejected Lots—A rejected lot shall be resubmitted for acceptance provided that the rejected lot is reworked, as necessary, to correct the nonconforming condition. Reworking shall consist of any procedure required to correct physical, mechanical, or dimensional deficiencies in nonconforming material to meet specification requirements without adversely affecting its other required characteristics.

APPENDIX

(Nonmandatory Information)

X1. RATIONALE

X1.1 This appendix provides general background information for the specification which is an adaptation of the former MIL-P-24503, “Packing Material, Graphitic, Corrugated Ribbon or Textured Tape and Die-Formed Ring.” The intent of this specification is to provide general guidance describing commercial packing requirements in the main body and military ship requirements in the supplementary requirements section. Note that Grade A military (ASTM/DoD) packing is restrictive in terms of the corrosion inhibitor allowed.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for
Packing Material, Graphitic or Carbon Braided Yarn

This standard is issued under the fixed designation F 2191; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers staple or continuous filament carbon/graphite yarn valve stem compression packing, suitable for use as end-rings on packing systems for valves. Intended services include steam, hydrocarbons, water and non-oxidizing chemicals. Where this specification is invoked as ASTM F 2191, Sections 1-18 apply. Where this specification is invoked as ASTM/DoD F 2191, Sections 1-18 and the Supplementary Requirements are applicable.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3. Terminology

3.1 base fiber density—bulk density of the base fiber before being coated or impregnated and braided into packing; expressed as lb/ft³.

3.2 braided flexible graphite—a braid constructed of continuous strands or strips of expanded flexible graphite tape or ribbons which may have been overwrapped or have imbedded reinforcing fibers.

3.3 carbon fibers—fibers used in braided packing are produced from viscose rayon, pitch, or polyacrylonitrile (PAN) and are defined as a yarn with a carbon assay of less than 99 %.

3.4 carbon yarns—manufactured from continuous or staple carbon fibers that are twisted or plied into continuous individual strands of between 6 and 18 µm in diameter.

3.5 carbon/graphite fibers—carbon/graphite fibers used in braided packing are produced from viscose rayon, pitch, or polyacrylonitrile (PAN).
3.6 *center or corner filler strands*—strands of fiber/yarn that run parallel to the longitudinal axis of the braid in the corners or center to control the internal density and dimensional stability of the braid.

3.7 *continuous*—individual fibers are almost infinite in length.

3.8 *continuous or staple carbon/graphite*—continuous or staple defines the length of the individual fibers in the carbonaceous yarn. Continuous means the fibers are infinite in length and staple means the individual fibers are at least 75 mm (3 in.) long and preferably 150 to 200 mm (6 to 8 in.) long. All of the fibers are between 6 to 18 µm in diameter and are twisted/plied into continuous strands called yarns.

3.9 *corrosion inhibitors*—additives to the yarn or braid to function in a passive or sacrificial manner to reduce galvanic corrosion such as embedded zinc powder, phosphorus, or barium molybdate.

3.10 *detrimental materials*—abrasive or chemically active constituents such as abrasive ash particles (in high ash content foils) or elemental materials as in Table 2.

3.11 *diagonal interlocking braid*—these strands criss-cross from the surface of the braid diagonally through the body of the braid and each strand is strongly locked by other strands to form an integral structure (see Fig. 1).

3.12 *dispersion*—various coatings or impregnants added to the base fibers or braid to facilitate handling, lubricate the fibers, accelerate break-in, or act as blocking agents during use.

3.13 *graphite fibers*—fibers used in braided packing are produced from viscose rayon, pitch, or polyacrylonitrile (PAN) and are defined as a yarn with a carbon assay of 99 % or higher.

3.14 *graphite yarns*—manufactured from continuous or staple graphite fibers that are twisted or plied into continuous individual strands between 6 to 18 µm in diameter.

3.15 *lot*—all finished packing of one size, type, class, and grade produced in a continuous run or at the same time and under essentially the same conditions.

3.16 *PAN*—polyacrylonitrile fibers used as precursors to manufacture carbon/graphite for braided packing.

3.17 *PTFE*—polytetrafluoroethylene. (Warning—Graphitic valve packing containing PTFE has been associated with accelerated valve stem corrosion.)

3.18 *specific gravity*—the ratio of the mass of a unit volume of a material at a stated temperature to the mass of the same volume of distilled water at the same temperature.

3.19 *square plait braid*—the strands in this type of braid interlock in a single plane and do not interlock through the body of the braid (see Fig. 1).

3.20 *staple carbon/graphite*—individual fibers are at least 75 mm (3 in.) long and preferably 150 to 200 mm (6 to 8 in.) long.

3.21 *unraveling*—a loss of the original braiding shape or dimensions of the cut end extending from the cut for a distance greater than that specified along the axis of the packing.

### 4. Classification

4.1 Classification—The material shall be of the following types, classes, and grades, as specified (see 5.1):

- **Type I**—Continuous carbon or graphite yarn.
- **Type II**—Staple carbon or graphite yarn.
- **Type III**—Braided flexible graphite.

4.1.1 Class 1—For use where detrimental material and lubricant content of the packing need not be controlled beyond normal manufacturing limits.

4.1.2 Class 2—For use where detrimental materials content must be controlled to limits specified herein.

4.1.3 Class 3—For use where detrimental materials content need not be controlled beyond normal manufacturing limits, and media temperatures do not exceed 500°F (260°C).

- **Grade A**—Treated with corrosion inhibitor.
- **Grade B**—No corrosion inhibitor.

### 5. Ordering Information

5.1 Acquisition Requirements—Acquisition documents must specify the following:

- **Title**, number, and date of this specification.
- **Type**, Class and Grade required (see Section 4).
- **Carbon** or graphite.
- **Type** of corrosion inhibitor.
- **Chemical properties** (see 7.1).
- **Inspection**, testing, and certification of the material shall be agreed upon between the purchaser and the supplier as part of the purchase contract.

5.1.1 Title, number, and date of this specification.

5.1.2 Type, Class and Grade required (see Section 4).

5.1.3 Carbon or graphite.

5.1.4 Type of corrosion inhibitor.

5.1.5 Chemical properties (see 7.1).

5.1.6 Inspection, testing, and certification of the material shall be agreed upon between the purchaser and the supplier as part of the purchase contract.

5.1.7 Size required (see 9.1). When pre-cut rings are desired, specify the braid cross-section, inside diameter, outside diameter, and number of rings required.

5.1.8 Put-up, if other than required by Table S4.1 (see Supplementary Requirements).

5.1.9 Application data.

5.1.10 Packaging requirements (see Section 18 and Supplementary Requirements).

5.1.11 Marking requirements (see 17.1 and Supplementary Requirements).

### 6. Materials and Manufacture

6.1 Materials and Manufacture—The material shall be as specified in 6.1.1-6.1.5.
6.1.1 Yarn:
6.1.1.1 Type I packing shall be made of continuous filament carbon or graphite yarn.
6.1.1.2 Type II shall be made of staple carbon or graphite yarn.
6.1.1.3 Type III shall be made of flexible graphite.

6.1.2 Packing:
6.1.2.1 Class 1 packing shall be made of Type I or Type II yarn and shall have a pure graphitic dispersion or carbon dispersion.
6.1.2.2 Class 2 packing shall be made of Type I yarn and shall have a pure graphite or carbon dispersion.
6.1.2.3 Class 3 packing shall be made of Type I or Type II yarn and shall have a pure graphite, or carbon dispersion and may be coated with polytetrafluoroethylene (PTFE) (see 7.2 and 13.9).

6.1.3 Coating and Corrosion Inhibiting Treatments:
6.1.3.1 Grade A—Grade A packing shall be provided with a powdered zinc (Zn) active corrosion inhibiting treatment or a passive inhibiting treatment such as phosphorus or barium molybdate. If required, both active and passive inhibitors shall be used.

6.1.3.2 Grade B—Grade B packing shall not contain corrosion inhibiting additives.

6.1.4 Packing Construction (Type I and Type II)—Packing shall be square (plait) braided for cross-sectional sizes smaller than 6 mm (1/4 in.). Cross-sectional sizes of 6 mm (1/4 in.) or greater shall use a diagonal interlocking type construction. The diagonal interlocking constructions shall consist of either single or plied yarns braided on 12, 18, 20, 24, 32, or 36 carrier braiding machines. Additional axial center, corner, and (stuffer) warp yarn(s) can be added within the braid as necessary to produce a dense square cross-section packing profile with good dimensional stability.

6.1.5 Mercury Exclusion—During manufacturing, fabrication, handling, packaging, and packing, the packing material shall not come in contact with mercury or mercury containing compounds.

7. Properties
7.1 Chemical and Physical Properties—Unless otherwise specified, the properties of the finished packing shall conform to the requirements of Table 1. Class 2 also requires compliance with Table 2.
7.2 PTFE Coating (Class 3 only)—If PTFE is used, it shall not exceed 10 % by mass of the packing (see 13.9) unless otherwise agreed to by the purchaser. (Warning—Graphitic valve packing containing PTFE has been associated with accelerated valve stem corrosion.)

7.3 Prohibited Additions—There shall be no intentional additions of any of the detrimental materials listed in Table 2 or any antimony (Sb), arsenic (As), bismuth (Bi), cadmium (Cd), gallium (Ga), indium (In), lead (Pb), mercury (Hg), silver (Ag), or tin (Sn), or, in the case of Grade B packing, zinc (Zn).

8. Other Requirements

8.1 Braid Geometry Retention—Untaped, cut ends shall not unravel more than 3 mm (1/8 in.) with the packing dry or wet (see 13.11). For example, packing 12 mm (1/2-in.) in cross section shall not unravel more than 3 mm (1/8 in.) at either end of the packing.

9.1 Sizes and Mass—Packing shall be furnished in the sizes shown in Table 3, or other size(s) as is ordered by the customer, (see Section 5 and 6.1.4). Packing shall be formed approximately square or rectangular in cross-section (either when straight or when placed about a shaft) within the dimensional tolerances of Table 3. When specified in the purchase document (see 5.1 and 13.2), the mass per linear foot (or other measure) shall be in accordance with the sizes listed in Table 4. Sizes not listed in Table 4 shall be as agreed between purchaser and manufacturer and specified in Section 5, Ordering Information. Minimum mass per linear foot should be included as a part of the bid and purchase documents.

9.1.1 Tolerance and Measurement Standards—The generally accepted method of measurements in the packing manufacturing environment is a hand held, direct reading, vernier caliper. To ensure concentricity, the inside diameter is measured using a ground dimensional plug gauge and the outside diameter is measured by the above (caliper) while the plug is inserted. Information regarding tolerance and measurement is available in the Guidelines for the Use of Compression Packings published by the FSA.

10. Workmanship, Finish and Appearance

10.1 Workmanship—The packing shall be free of defects that have the potential to affect its serviceability as defined in Table 5.

10.2 Construction—The sample shall be visually examined and confirmed to be of the correct braid construction (square plait braid or diagonal interlocking braid) for the ordered size (see 5.1 and 6.1.4).

11. Quality Assurance

11.1 Quality Systems—Manufacturers shall be prepared to document use of a quality system such as compliance with an ISO 9000 series program or similar program.

12. Specimen Preparation

12.1 Specimen Preparation—Buyer and seller shall agree on specimen preparation.

13. Test Methods

13.1 Tests—In the event that tests are required as part of the purchasing requirements 5.1, tests shall be made in accordance with the following tests or by way of alternate methods of analysis with equal to or improved accuracy and precision. The use of an alternate analytical method requires the prior written consent of the purchasing party before acceptance will be allowed.

13.2 Size—Before unbraiding, the size shall be determined by measuring each sample selected for visual examination (see Table 3). A steel rule with 1 mm (1/32 in.) divisions accurate to 1 mm (1/32 in.) or a steel slide caliper with 0.5 mm (1/64 in.) divisions shall be used (see 9.1).

13.3 Mass—The mass shall be determined using a specimen at least 609.6 mm (2 ft) in length for measurement in conjunction with the values of Table 4.

13.4 Carbon Assay—The sample shall be dried to a constant mass at 149 ± 3°C (300 ± 5°F) before testing. For Grade A packing only, the test shall be conducted prior to the corrosion inhibiting treatment or the added mass of the corrosion inhibitor shall be determined and subtracted from the base mass of the sample. The percent carbon shall be based upon mass of the dried sample. This determination shall be made in accordance with Test Methods D 3178 or an alternate method of analysis with equal or improved accuracy and precision (see Table 1).

13.5 Ash Content—The ash content shall be determined in accordance with Test Method C 561 (see Table 1). For Grade A packing only, the test shall be conducted prior to the corrosion inhibiting treatment or the added mass of the corrosion inhibitor shall be determined and subtracted from the base mass of the sample.

13.6 Specific Gravity—This determination shall be made in accordance with Test Method C 135, modified as follows: (Alternative methods of analysis with equal or improved accuracy and precision (see Table 1) can be used upon receipt of prior written consent and approval by the purchaser.)

13.6.1 Preparation for Test Method C 135—A 50 g (1.7637 oz) sample shall be prepared for grinding by unbraiding, cutting, or otherwise reducing the braided packing to pieces not larger than 3 mm (1/8 in.).

NOTE 1—Test Method C 135 uses a water pycnometer test method. Test procedures using a gas pycnometer-based analytical method shall forego the need to reduce of the sample to its fiber state.

13.7 Moisture Content—The moisture content shall be determined in accordance with Test Method C 562 (see Table 1).

13.8 Detrimental Materials Tests—For determination of the detrimental materials listed in Table 2 for Class 2 only, the test
methods of Table 6 or alternate methods of equal or improved accuracy and precision shall be used.

13.9 Analysis for PTFE Coating (Class 3 only)—A 5 g specimen of packing shall be placed in a crucible and heated at 104 ± 6°C (220 ± 6°F) to constant mass (original dry mass) at room temperature. Then the specimen shall be heated at 316 ± 6.5°C (600 ± 10°F) for 24 h, cooled, and the mass determined. The same specimen shall then be heated at 482 ± 16°C (900 ± 25°F) for 3 h, cooled, and the mass determined. After the 482°C (900°F) heating, the crucible mass shall be redetermined without the specimen unless a platinum crucible was used. The new mass of the crucible shall be used to determine the mass of the residue after heating. Heating shall be done in a ventilated hood to avoid exposure to toxic vapors. The percentage of PTFE shall be calculated as follows, based on an average of three determinations (see 7.2).

\[
\text{Percent PTFE} = \frac{100(F - N)}{W}
\]

where:

\( W \) = average original dry mass of specimens after extraction,

\( F \) = average mass of residue in crucibles after heating at 316°C (600°F), and

\( N \) = mass of the crucible.

</table>
13.10 Compression Recovery—Three specimens, each 44 ± 3 mm (1.750 ± 0.125 in.) long, shall be prepared from the sample and the results of the following test of each specimen averaged for comparison with the compression recovery limit of Table 1.

13.10.1 Center the specimen on a flat plate which is larger than the specimen and has its upper surface perpendicular (±2°) to the load to be applied. Place a flat plate of similar size on top of the specimen so that its lower surface is parallel (±2°) to the upper surface of the bottom plate. The upper plate shall weigh 2.27 ± 0.45 kg (5 ± 1 lb). Both plates shall be rigid and maintained parallel during the testing. After the weight of the upper plate has been applied to the specimen for at least 15 s, measure and record the thickness \( P \) of the preloaded specimen. Several measurements about the circumference of the test plate shall be taken and averaged for this, and subsequent, measurements.

13.10.2 Apply the major load, by either the top or bottom plate, along an axis passing through the center of the specimen in a slow, uniform manner so that the major load is attained within 20 ± 5 s. The major load is that load which will produce a stress of 316.4 kg/cm² ± 10 % (4500 lbs/in.² ± 10 %) on the area of the specimen initially in contact with the lower test plate.

13.10.3 Maintain the major load for at least 60 s and measure and record the thickness \( M \) of the fully loaded specimen.

13.10.4 Immediately remove the major load and after about 60 s measure and record the recovered thickness \( R \) under the original preload.

13.10.5 Calculate the percent compression recovery (PCR) as follows:

\[
\text{PCR} = \left( \frac{R - M}{P - M} \right) \times 100
\]

13.11 Braid Geometry Retention—Cut a 50 ± 1.5 mm (2 ± ½ in.) length packing (the ends shall not be taped prior to or after cutting). Soak the test piece in room temperature water for 15 min, minimum. The packing shall not unravel at the ends more than 3 mm (½ in.) at either end (see 8.1).

14.1 Inspection and testing of the material shall be agreed upon between the purchaser and the supplier as part of the purchase contract (see 5.1).

15. Rejection

15.1 Materials that fail to conform to the requirements of this specification shall be rejected. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of testing, the producer shall make claim for a rehearing or provide for third party testing.

16. Certification

16.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been tested and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

16.2 Detrimental Materials Control—For Class 2 material only, the vendor shall provide certification that the limits of Table 2 have been met and that low melting metals (anitmony (Sb), arsenic (As), bismuth (Bi), cadmium (Cd), lead (Pb), tin (Sn), gallium (Ga), indium (In), silver (Ag), mercury (Hg) and zinc (Zn) [zinc for Grade B only]) have not been added as intentional constituents. Instead of specific test results for the lot to be delivered, certifications shall be based on tests of both raw materials and production lots of similar finished packing material over an extended time period (not exceeding three years between tests). Any change to manufacturing processing which affects product composition, including changes to raw material, binders, or inhibitors (Grade A) shall require additional testing to form the basis for future certifications.

17. Product Marking

17.1 Marking—For commercial shipment, marking shall be in accordance with accepted industry practices or as required in the purchase contract (see 5.1). Marking shall include type of corrosion inhibitor, if any.

18. Packaging

18.1 Commercial Packaging—Commercial packaging shall be in accordance with Practice D 3951 or as required in the purchase contract (see 5.1).
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract or order. All of these Supplementary Requirements and Sections 1–18 are applicable where this specification is invoked as ASTM/DoD F 2191. This specification is adapted from MIL-P-24583.

S1. DoD Intended Use

S1.1 Type I packings are intended for general shipboard service as anti-extrusion end-rings to be used in conjunction with corrugated ribbon or preformed ring graphitic packing material in valves. Grade A packing is intended for use in valves with non-corrosion resistant (for example, carbon steel, 400 series stainless steel) stem and packing gland parts.

S2. Classification

S2.1 The Type (I and II) and Class classifications of this specification correspond to the Type and Class classifications of MIL-P-24583.

S2.2 The Grade B classification of this specification corresponds to the Grade N classification of MIL-P-24583.

S2.3 The Grade A classification of this specification, utilizing zinc powder corrosion inhibitor only, corresponds to the Grade I classification of MIL-P-24583.

S3. Materials and Manufacture

S3.1 Coating and Corrosion Inhibiting Treatments:

S3.1.1 Grade A—Grade A packing shall be provided with a powdered zinc (Zn) active corrosion inhibiting treatment only (2 % zinc, by weight, minimum).

S3.1.2 Grade B—Grade B packing shall not contain corrosion inhibiting additives.

S4. Dimensions and Tolerances

S4.1 Put-Up—Unless otherwise specified (see Section 5), packing shall be uniformly coiled on spools or reels of the size specified (see Section 5) in accordance with Table S4.1. No more than three segments of packing shall be provided on the smallest spool or reel.

S5. Quality Assurance

S5.1 As a minimum, manufacturers shall provide and maintain an inspection system that meets the requirements of ANSI/ASQC Q9003.

S6. Test Methods

S6.1 Examination for Visual and Dimensional Defects—Units shall be examined for visual and dimensional defects as follows:

S6.1.1 Size—The size of each unit selected shall be measured for conformance with the requirements of Section 9, including Table 3, and 13.2.

S6.1.2 Visual Examination—Each unit selected shall be visually examined to determine conformance with the requirements of 10.1, including Table 5.

S6.1.3 Construction—Each unit selected shall be visually examined to determine conformance with the requirements of 10.2.

S6.2 Examination for Preparation for Delivery—Each unit selected shall be visually examined to determine compliance with packaging requirements (see Sections 5 and 18) and marking requirements (see Sections 5 and 9).

S6.3 Simulated Performance—The test shall be conducted in an apparatus designed to simulate conditions in valves in actual service. A schematic of the test rig is shown in Fig. S6.1. The valves used in the simulator shall have glands and stems that are in new condition. The entire piping system and valves shall be insulated so as to minimize heat loss. Thermocouples shall be installed so as to indicate the actual steam temperature. The simulator shall be capable of holding a temperature of 524 ± 14°C (975 ± 25°F) and a pressure of 84 ± 3.5 kg/cm² (1200 ± 50 lb/in.²) for the duration of the test. The packing shall be installed and the gland initially adjusted so that no leakage occurs with the system at its operating temperature and pressure.

pressure. The valve shall be fully cycled manually not less than once every half-hour (full close to full open). The following schedule shall be followed for running the test (test need not be conducted over a weekend period, if desired):

- 12 days at temperature 524°C (975°F) and 84.35 kg/cm² (1200 ± 50 lb/in.²) pressure
- 35 ± 5 days at ambient temperature and pressure (system shut down; valves need not be cycled)
- 5 days at 524°C (975°F) and 84 ± 3.5 kg/cm² (1200 ± 50 lb/in.²) pressure

There shall be no steam leakage from the packing gland during the simulated performance test at a temperature of 524°C (975°F) and a pressure of 84 ± 3.5 kg/cm² (1200 ± 50 lb/in.²). There shall also be no corrosion or degradation of the packing gland at the completion of the test. Any leakage or gland adjustment shall be recorded. This test is equivalent to the simulated performance test of MIL-P-24503.

S7. Inspection and Testing

S7.1 Unless otherwise specified (see Section 5), first article testing and quality conformance testing are required. The inspections and tests making up the first article and quality conformance testing are as follows:

S7.2 First Article Tests—First article testing shall consist of the examinations and tests of Table S7.1.

S7.3 Quality Conformance Tests—Quality conformance testing shall be in accordance with Table S7.1.

S7.4 Sampling:

S7.4.1 Sampling for Visual and Dimensional Examination (S6.1)—As a minimum, the contractor shall randomly select a quantity of sampling units from each lot of graphitic or carbon braided yarn packing material in accordance with Table S7.2 and subject them to the examinations for visual and dimensional defects of S6.1. The sample size depends on the lot size. If one or more defects are found in any sample, the entire lot shall be rejected. The contractor has the option of screening 100% of the rejected lot for the defected characteristics or providing a new lot, which shall be selected in accordance with the sampling plan herein. The contractor shall maintain for a period of three years after contract completion, records of inspections, tests, and any resulting rejections.

S7.4.2 Sampling for Chemical and Physical Property and Detrimental Material Tests—A single random sample shall be selected from each lot for the testing of 13.3-13.11.

S7.4.3 Sampling for Examination for Preparation for Delivery (S6.2)—The lot size shall be the number of shipping containers. Sampling shall be in accordance with Table S7.2.

S7.4.4 Sampling for Simulated Performance Test (S6.3)—A sample of sufficient size shall be selected for the simulated performance test.

S8. Certification

S8.1 Simulated Performance Test—After the simulated performance test is once performed acceptably, providing product
composition and processing has not been changed, a certificate of compliance, citing the test report or document accepting compliance with the test requirement, shall be provided thereafter.

S9. Product Marking

S9.1 Minimum Product Marking—Item description marking shall include, as a minimum, the size, type, class, grade and type of inhibitor (if any) of the packing material. In addition, the item description marking shall include the phrase “ASTM/DoD F 2191” to identify the applicability of this specification and any special marking which may be required, such as bar coding (see Section 5). Marking for DoD procurements shall be in accordance with MIL-STD-129.

S9.2 Spool/Reel Marking—If packing is to be provided on spools or reels, the required information of S9.1, and the National Stock Number and contract number, shall be marked on the spool or reel.

S10. Rejection

S10.1 Known Defects—Materials that fail to conform to the requirements of this specification shall not be offered for delivery.

S10.2 Buyer Testing—The buyer reserves the right to perform any of the inspections and tests set forth in this specification. Materials that fail to conform to the requirements of this specification shall be rejected. Rejection will be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of testing, the producer shall make claim for a rehearing or provide for third party testing.

S10.3 Replacement of Test Specimens—A test specimen shall be discarded and a replacement specimen selected from the same lot of material under the following conditions:

S10.3.1 Where the specimen is incorrectly prepared.
S10.3.2 Where the test procedure is incorrect.
S10.3.3 Where there is a malfunction of the testing equipment.
S10.3.4 Where a flaw that is not indicative of an inferior or defective lot of material develops during the test.

S10.4 Retests—Retests are only permitted for ash content, graphite purity, bulk density and detrimental material tests. Retests shall be performed on twice the number of specimens that were originally nonconforming. Retest specimens shall be taken in the vicinity of the initial location of a failed specimen. If any of the retest specimens fail, the lot shall be rejected with no further retesting permitted.

S10.5 Resubmittal of Rejected Lots—A rejected lot can be resubmitted for acceptance provided that the rejected lot is reworked, as necessary, to correct the nonconforming condition. Reworking shall consist of any procedure required to correct physical, mechanical or dimensional deficiencies in nonconforming material to meet specification requirements without adversely affecting its other required characteristics.

APPENDIX

(Nonmandatory Information)

XI. RATIONALE (COMMENTARY)

This appendix provides general background information for this specification, which is an adaptation of the former MIL-P-24583, “Packing Material, Graphitic or Carbon Yarn.” The intent of this specification is to provide general guidance describing commercial packing requirements in the main body and military ship requirements in the supplementary requirements section. It is noted that some Grade A military ASTM/DoD packings are restrictive in terms of the corrosion inhibitors.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Test Method for Determining and Reporting the Berthing Energy and Reaction of Marine Fenders

This standard is issued under the fixed designation F 2192; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

A marine fender is an energy-absorbing device that is typically secured against the face of a marine facility or a ship’s hull for the purpose of attenuating the forces inherent in arresting the motion of berthing vessels safely. Most modern fenders fall into three general classifications based on the material used to absorb energy: (1) solid rubber fenders in which the material absorbs the energy, (2) pneumatic (air-filled) fenders in which air absorbs the energy, and (3) foam-filled fenders in which the foam core absorbs the energy.

1. Scope

1.1 This test method establishes the recommended procedures for quantitative testing, reporting, and verifying the energy absorption and reaction force of marine fenders. Marine fenders are available in a variety of basic types with several variations of each type and multiple sizes and stiffnesses for each variation. Depending on the particular design, marine fenders may also include integral components of steel, composites, plastics, or other materials. All variations shall be performance tested and reported according to this test method.

1.2 There are three performance variables: berthing energy, reaction, and deflection. There are two methods used to develop Rated Performance Data (RPD) and published performance curves for the three performance variables.

1.3 The primary focus is on fenders used in berthing and ship-to-ship applications for marine vessels. This testing protocol does not address small fendering “bumpers” used in pleasure boat marinas, mounted to hulls of work boats, or used in similar applications; it does not include durability testing. Its primary purpose is to ensure that engineering data reported in manufacturers’ catalogues are based upon common testing methods.

1.4 The values stated in SI units are to be regarded as the standard.

1.5 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

3. Significance and Use

3.1 General:

3.1.1 All testing shall define fender performance under velocities that decrease linearly or that are proportional to the square root of percent of remaining rated energy.

3.1.2 Rated performance data (RPD) and manufacturers’ published performance curves or tables, or both, shall be based on: (1) initial deflection (berthing) velocity of 0.15 m/s and decreasing to no more than 0.005 m/s at test end, (2) testing of fully broken-in fenders (break-in testing is not required for pneumatic fenders), (3) testing of fenders stabilized at 23 ± 5°C (excluding pneumatic fenders; see 6.3), (4) testing of fenders at 0° angle of approach, and (5) deflection (berthing) frequency of not less than 1 h (use a minimum 5-min deflection frequency for pneumatic fenders.).

3.1.3 Catalogues shall also include nominal performance tolerances as well as data and methodology to adjust performance curves or tables or both for application parameters different from RPD conditions. Adjustment factors shall be provided for the following variables: (1) other initial velocities: 0.05, 0.10, 0.20, 0.25, and 0.30 m/s; (2) other temperatures: +50, +40, +30, +10, 0, −10, −20, −30; and (3) other contact angles: 3, 5, 8, 10, 15°. In addition, RPD shall contain a cautionary statement that published data do not necessarily apply to constant-load and cyclic-loading conditions. In such cases, designers are to contact fender manufacturers for design assistance.

---

1 This test method is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.

3.1.4 Adjustment factors for velocity and temperature shall be provided for every catalogue compound or other energy absorbing material offered by each manufacturer.

3.2 Fender Testing—Performance testing to establish RPD must use either one of two methods:

3.2.1 Method A—Deflection of full-size fenders at velocities inversely proportional to either (1) the percent of either (a) rated deflection or (b) remaining rated energy or (2) the square root of the percent of rated energy absorbed. Test parameters shall be as defined for published RPD. RPD tests shall start at 0.15 m/s. Tests to establish adjustment factors for initial berthing velocities other than 0.15 m/s shall start at those other initial velocities.

3.2.2 Method B—Deflection of full size fenders at constant velocity with performance adjusted by velocity factors developed from model tests. Velocity factors shall be the ratio of performance test results of models under the following conditions: (1) a constant strain rate similar to the strain rate of the full-size fender at its test speed, and (2) decreasing speed deflection with initial strain rate similar to that of the full-size fender under RPD deflection conditions.

3.2.3 The RPD for pneumatic fenders shall be determined using either Method A or Method B with miniature-size fenders; in which case, the compression performance of air shall be directly extrapolated from the test data of reduced scale models.

4. Apparatus

4.1 The test apparatus shall be equipped with load cell(s) and linear transducer(s) capable of providing continuous monitoring of fender performance. The test apparatus shall be capable of recording and storing load-cell and transducer data at intervals of <0.01 H, where H is a fender’s nominal height, and storing manually entered inputs. Output information shall include, as a minimum:

4.1.1 Serial number and description of test item,
4.1.2 Date, time at start, and time at end of test,
4.1.3 Location of test facility and test apparatus ID,
4.1.4 Stabilization temperature of test specimen,
4.1.5 Test ambient temperature, and
4.1.6 Graphic plot(s) of: (1) deflection velocity versus deflection (optional) (If not plotted, deflection velocity and its characteristics shall be separately noted.), (2) reaction versus deflection, and (3) energy versus deflection.

4.2 For fender tests, all equipment used to measure and record force and deflection shall be calibrated and certified accurate to within ±1%, in accordance with ISO or equivalent JIS or ASTM requirements. Calibration shall be performed within one year of the use of the equipment, or less, if the normal calibration interval is shorter than one year. Calibration of test apparatus shall be performed by a qualified third-party organization, using instrumentation that is traceable to a certified, national standard.

4.3 The test apparatus shall deflect specimens according to Section 5.

5. Procedure

5.1 The performance test shall deflect specimens according to either of the two methods listed below. Clear and unambiguous calculations must be provided for any adjustments made to the test results.

5.2 Method A:

NOTE 1—Steps 5.2.1 and 5.2.2 do not apply to pneumatic fenders. Step 5.2.3 may be omitted for pneumatic fenders, provided internal pressure is adjusted to the manufacturer’s specified value for the ambient test temperature.

5.2.1 Break in the specimen by deflecting it three or more times to its rated deflection, or more, as recommended by the manufacturer.

5.2.2 Remove load from specimen and allow it to “recover” for 1 h or more, as recommended by manufacturer.

5.2.3 Before conducting performance test, stabilize fender temperature in accordance with 6.1. Temperature-stabilizing time can include time for 5.2.1 and 5.2.2.

5.2.4 Deflect specimen once at a continuously decreasing deflection velocity as defined in one of the equations below:

\[ V = V_0 \frac{(D - d)}{D} \text{ or } 0.005 \text{ m/s whichever is greater} \quad (1) \]

or

\[ V = V_0 \sqrt{(E - e)/E} \text{ or } 0.005 \text{ m/s whichever is greater} \quad (2) \]

where:

- \( V \) = instantaneous deflection velocity of fender,
- \( V_0 \) = initial deflection velocity, where \( V_0 = 0.05, 0.10, 0.15, 0.20, 0.25, \) or \( 0.30 \) m/s,
- \( D \) = rated deflection,
- \( d \) = instantaneous deflection,
- \( E \) = rated energy absorption of fender, and
- \( e \) = instantaneous running total of energy absorbed.

Initial velocity shall be appropriate for particular testing purpose.

5.2.5 Stop test when deflection reaches rated deflection, or more, as recommended by the manufacturer.

5.2.6 Adjust performance to rating temperature (23 ± 5°C), if required, or to desired application temperature by multiplying both energy and reaction results by temperature factor (TF) (see 6.3).

5.3 Method B:

NOTE 2—Steps 5.3.1 and 5.3.2 do not apply to pneumatic fenders. Step 5.3.3 may be omitted for pneumatic fenders, provided internal pressure is adjusted to the manufacturer’s specified value for the ambient test temperature.

5.3.1 Break in specimen by deflecting three or more times to its rated deflection, or more, as recommended by the manufacturer.

5.3.2 Remove load from specimen and allow it to “recover” for 1 h or more, as recommended by manufacturer.

5.3.3 Before conducting performance test, stabilize fender temperature in accordance with 6.1. Temperature-stabilizing time can include time for 5.3.1 and 5.3.2.

5.3.4 Deflect specimen once at a constant deflection velocity.

5.3.5 Stop test when deflection reaches rated deflection, or more, as recommended by the manufacturer.
5.3.6 Adjust performance to rated temperature (23 ± 5°C), if required, or to desired application temperature by multiplying both energy and reaction results by temperature factor (TF) (see 6.3).

5.3.7 Adjust performance to RPD initial deflection velocity (0.15 m/s) or to desired initial berthing velocity, if required, by multiplying both energy and reaction results by velocity factor (VF) (see 6.2).

6. Supporting Procedures

6.1 Temperature Stabilization:

6.1.1 Test temperature for full-size specimens is defined as the same as stabilization temperature, as long as ambient temperature at test apparatus is within ±15°C of stabilization temperature and testing is completed within 2 h of the specimen’s removal from the temperature-controlled environment.

6.1.2 To stabilize temperature, store specimen at a constant temperature ±5°C. Record air temperature of space where specimen is stored within 3 m of specimen surface, either continuously or twice a day, no less than 10 h apart.

6.1.3 Stabilization time shall be not less than 20x 1.5 days or more as recommended by the manufacturer, rounded to the next whole day (x = dimension of greatest rubber thickness, in meters), after curing plus 20x 1.5 days, rounded to the next whole day, after being in an ambient temperature differing from stabilization temperature by more than 10°C for more than 8 h.

6.2 Velocity Factor (VF)—One of the following protocols shall be followed to determine VF for every combination of fender configuration, initial velocity other than RPD velocity, fender element standoff and energy-absorbing material. Specimens for determining VF may be either full-size fenders or models, as noted below. Pneumatic fenders do not require a VF.

6.2.1 Method A—Testing of full-size fenders at actual, decreasing rate deflection velocity.

6.2.1.1 Test full-size fenders per 5.2 at 0.15-m/s initial velocity and 23 ± 5°C.

6.2.1.2 Repeat at other initial velocities.

6.2.1.3 Derive the VFs from the data in 6.2.1.1 and 6.2.1.2 per the following method:

1. Energy velocity factor and reaction velocity factor by Method A, VF<sub>ea</sub> and VF<sub>ra</sub>, shall be defined by the following equations:

\[ VF_{ea} = \frac{E_a}{E_{RPD}} \]
\[ VF_{ra} = \frac{R_a}{R_{RPD}} \]

where:
- \( E_a \) = energy at alternative initial velocity,
- \( R_a \) = reaction at alternative initial velocity,
- \( E_{RPD} \) = energy at RPD initial velocity, and
- \( R_{RPD} \) = reaction at RPD initial velocity.

6.2.2 Method B—Testing of model at both constant and decreasing strain rates.

6.2.2.1 Calculate the strain rate of the full-size fender when it is deflected at the constant velocity of 0.0003 to 0.0013 m/s (2 to 8 cm/min).

6.2.2.2 Test the model, per 5.3, at 23 ± 5°C, at the strain rate calculated in 6.2.2.1 (± 10%).

6.2.2.3 Calculate the initial strain rate of the full-size fender when it is deflected at the desired initial berthing velocity.

6.2.2.4 Test the same model used in 6.2.2.2 per 5.3, at 23 ± 5°C, beginning at the initial strain rate calculated in 6.2.2.3 (±10%).

6.2.2.5 Derive velocity factors for energy and reaction, VF<sub>e</sub> and VF<sub>r</sub>, from the data in 6.2.2.2 and 6.2.2.4 per the following equations:

\[ VF_e = R_e/R_{test} \]
\[ VF_r = E_r/E_{test} \]

where:
- \( E_e \) = energy per 6.2.2.4,
- \( E_{test} \) = energy per 6.2.2.2,
- \( R_e \) = reaction per 6.2.2.4, and
- \( R_{test} \) = reaction per 6.2.2.2.

6.3 Temperature Factor (TF)—Temperature factors (TF) for pneumatic fenders may be calculated using ideal gas laws. For every urethane, foam or rubber compound, the TFs shall be determined by the following procedure.

6.3.1 Conduct standard performance tests on temperature-stabilized specimens using either Method A or Method B, per one of the two methods described below:

6.3.1.1 (A)—Stabilize specimens at test temperature per 6.1.2 and 6.1.3. Specimens shall be either full-size fenders or models not smaller than 0.1 m in height. Test specimens in test apparatus maintained at test temperature for duration of test.

6.3.1.2 (B)—Stabilize specimens at test temperature per 6.1.2 and 6.1.3. Specimens shall be either full-size fenders or models not smaller than 0.3 m in height. Test specimens at room temperature. Test must be completed within 15 min of sample’s removal from temperature-controlled environment.

6.3.2 Specimens shall be stabilized at the following temperatures: -30, -20, -10, 0, +10, +23, +30, +40, and +50°C. The TFs for each of these temperatures, TF<sub>t</sub>, where \( t \) is the number designating the reference temperature, shall then be calculated by the following equations:

\[ TF_t = R_t/R_{23} \]
\[ TF_{23} = E_{23}/E_{23} \]

where:
- \( R_t \) = reaction at temperature other than 23°C (highest reaction below 0.35 H deflection),
- \( R_{23} \) = reaction at 23°C (highest reaction below 0.35 H deflection),
- \( E_t \) = energy at temperature other than 23°C, and
- \( E_{23} \) = energy at 23°C.
7. Verification/Quality Assurance Testing

7.1 Energy/Reaction Compliance Testing—Verification/quality assurance testing to determine compliance with either RPD or other customer-specified energy and reaction requirements (required performance) shall be performed in a test apparatus, as described in Section 4. Samples for verification testing shall be actual fender elements fabricated for the project location. For cylindrical foam, pneumatic, and hydropneumatic fenders larger than 1800-mm diameter by 3600-mm long, the tests of a 1200-mm diameter by 2000-mm long or larger fender may be scaled to demonstrate the energy and reaction ratings of the fender. The projected fender and the test fender shall both be constructed with the same materials, have the same general configurations of the ends, and have the same skin thickness-to-diameter ratio. Scaling shall be conducted per the following equations:

\[
\text{Energy} = \frac{\text{test fender energy} \times \text{diameter ratio squared} \times \text{overall length ratio}}{\text{test fender reaction} \times \text{diameter ratio} \times \text{overall length ratio}}
\]

7.1.1 Test sample according to Method A (5.2) or Method B (5.3), adjusting performance to required performance as specified in 5.2.6 or 5.3.6, and 5.3.7.

7.1.2 A fender provides the required performance (required energy and reaction) within production tolerances if it meets both the following requirements simultaneously at any point during the test described in 7.1.1:

7.1.2.1 Velocity-and-temperature-adjusted energy absorbed is equal to or greater than the required energy multiplied by the nominal energy tolerance (low end) specified in its catalogue data.

7.1.2.2 Velocity-and-temperature-adjusted reaction is no more than the required reaction multiplied by the nominal reaction tolerance (high end) specified in its catalogue data.

7.2 Other Testing—Other testing requirements, including selection of sampling scheme, shall be as agreed between customer and fender manufacturers.

8. Effect of Contact Angle Testing

8.1 Manufacturers shall include graphs or tables defining the effect of deflecting fenders at the contact angles listed in 3.1.3 (3). This data may be generated mathematically or by testing performed on either actual fender elements or on scale models or arrays. It must reflect the effect of angle contact on an entire fender assembly, not just an individual element.

8.2 The following is the procedure for defining the effect of each contact angle/configuration combination. The test shall be made on the horizontal and vertical axes of the fender unit:

8.2.1 Using a test apparatus as described in Section 4, execute the steps of the test procedure defined in 5.2 or 5.3.

8.2.2 Determine the base-case energy rating for 0° contact angle of the specimen at the deflection or reaction limit recommended by the manufacturer.

8.2.3 Allow the specimen to recover outside the test apparatus for at least 1 h or more as recommended by the manufacturer.

Note: A 5-min recovery period is sufficient for pneumatic fenders.

8.2.4 Attach a “wedge” to the test apparatus’ moveable surface to simulate the desired contact angle and repeat the test cycle only of 8.2.1.

8.2.5 Determine the energy rating of the specimen in the contact angle test at the manufacturer’s recommended deflection or reaction limit.

8.2.6 The contact-angle factor is the energy determined in 8.2.5 divided by that determined in 8.2.2.

8.3 This factor is applied to energy only. No factor need be applied to reaction, since the maximum reaction is as defined by the 0° contact-angle performance. For combined horizontal and vertical contact angles, multiply the contact-angle factor for the horizontal direction by the contact-angle factor for the vertical direction.

9. Precision and Bias

9.1 No information is presented about either the precision or bias of Test Method F 2192 measuring the performance of fenders. The precision and bias information is being determined and will be available on or before May 2006 following Practice E 691.

10. Keywords

10.1 berthing; berthing energy; deflection; energy absorption; fender; fender testing; rated performance data; reaction; temperature factor; velocity factor
1. Scope

1.1 This guide provides assistance in the choice of computing hardware resources for ship and marine environments and describes:

1.1.1 The core characteristics of interoperable systems that can be incorporated into accepted concepts such as the Open System Interconnection (OSI) model;

1.1.2 Process-based models, such as the Technical Reference Model (TRM), that rely on interoperable computing hardware resources to provide the connection between the operator, network, application, and information; and,

1.1.3 The integrated architecture that can be used to meet minimum information processing requirements for ship and marine environments.

1.2 The use of models such as OSI and TRM provide a structured method for design and implementation of practical shipboard information processing systems and provides planners and architects with a roadmap that can be easily understood and conveyed to implementers. The use of such models permit functional capabilities to be embodied within concrete systems and equipment.

1.3 The information provided in this guide is understood to represent a set of concepts and technologies that have, over time, evolved into accepted standards that are proven in various functional applications. However, the one universal notion that still remains from the earliest days of information processing is that technological change is inevitable. Accordingly, the user of this guide must understand that such progress may rapidly invalidate or supersede the information contained herein. Nonetheless, the concept of implementing ship and marine computing systems based on these functional principles allows for logical and rational development and provides a sound process for eventual upgrade and improvement.

3. Significance and Use

3.1 This guide is aimed at providing a general understanding of the various types of hardware devices that form the core of information processing systems for ship and marine use. Ship and marine information processing systems require specific devices in order to perform automated tasks in a specialized environment. In addition to providing information services for each individual installation, these devices are often networked and are capable of supplementary functions that benefit ship and marine operations.

3.2 A variety of choices exists for deployment of information processing devices and greatly increases the complexity of the selection task for ship and marine systems. The choice of a particular device or system cannot be made solely on the singular requirements of one application or function. Modern information processing systems are usually installed in a complex environment where systems must be made to interact with each other. Ship and marine installations add an even further layer of complexity to the process of choosing adequate computerized systems. This guide aims to alleviate this task by giving users specific choices that are proven technologies that perform in a complex environment.

3.3 Hardware resources used in ship and marine installations are a result of careful consideration of utility and function. These resources may require some physical special-
expensive and tailored to the user’s individual preference because application interoperability will not be a significant factor.

4.5 Today, however, most application software is hosted on the client and interoperability among clients is a critical factor. Even within the client-server application architecture, application specific software resident on the client is still prevalent. This demands consistency of client workstations across an entire installation to achieve seamless interoperability. Table 1 outlines a rationale for the client-server deployment strategy.

4.6 Driven by the current state of client-server technology, the general philosophy for implementing computing resources is the concept of homogeneous clients and heterogeneous servers. Homogeneous clients facilitate providing a consistent interface between the user and the system and make system support and maintenance less complex. Heterogeneous servers support the various computing requirements of applications needed to support ship and marine operations. The same advantages that homogeneous clients enjoy can be achieved if servers are homogeneous as well. Independent of whether or not the server suite employed is heterogeneous or homogeneous, it is important that they perform their function transparently to the user (that is, the user neither knows nor cares about the location, number, or vendor of the server being used.) Requiring servers to be homogeneous would restrict the introduction of new server technology, choking innovation and preventing the installation from taking advantage of advances in computing such as massively parallel processors.

5. Computing Hardware

5.1 Computing Resources—Computing resources consist of many computing hardware components and configurations of these components. This section covers the various hardware components that make up a computing resource system and examines how these components are commonly configured.

<table>
<thead>
<tr>
<th>TABLE 1 Client-Server Deployment Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Rationale for Heterogeneous Servers</strong></td>
</tr>
<tr>
<td>The server must be tailored to the specific application that may not be supportable by computers most prevalent in the marketplace. Many applications work well in their current computing environment and it is not cost effective to change. It is not practical to have all applications on a common server for multiple reasons including the need to maintain competition between computer developers and vendors. Encourages innovation by not restricting the type of computer used for the development of applications. Allows for a common, consistent user interface. Maximizes interoperability.</td>
</tr>
<tr>
<td><strong>Rationale for Homogeneous Clients</strong></td>
</tr>
<tr>
<td>Minimizes re-training required as users transfer to different organizations within the enterprise. Maximizes the ability to use common support and maintenance skills, parts and labor; thereby minimizing cost. Maximizes portability of support for applications across the enterprise as well as portability of user skills. Allows for economies of scale in both procurement (volume discounts) and support (more focused skill set for help desk personnel).</td>
</tr>
</tbody>
</table>
5.2 Component Technologies—The major hardware components of Computing Resources are the Central Processing Unit (CPU), one or more backplane buses, main memory (both RAM and cache), Input/Output (I/O) interfaces, and peripherals. This section will examine each of these areas and provide guidance on the selection of these component technologies as part of a computing resource system.

5.2.1 CPU—The CPU is the “engine” of the computer system and, combined with the OS (operating system), forms the core of the computing resource. Since the OS drives many decisions concerning the computer resource, a CPU that is compatible with the OS becomes an overriding factor in determining the type of CPU. Other than the OS, the main factors to consider in determining the type of CPU for the computer are processing speed (performance) and cost. For computing resources, such as servers and multiprocessors, scalability of the number of processors can be a significant factor in determining CPU.

5.2.2 Bus—The computer bus connects the different components of the computer resource together and allows them to pass data between them at high speeds. Computer resource configurations, such as personal workstations, often limit or determine the type of bus that will be used. Often there are multiple buses connected together to allow for multiple types of component cards or to extend a non-expandable system bus. Considerations in determining the type of bus to use are: number and type of commercial products compatible with the bus architecture, number of parallel data bit lines, clock speed, and cost. Once the appropriate bus architecture is determined, an important computer resource factor becomes how many interface slots are available on the bus for component cards.

5.2.2.1 Use buses that provide the necessary performance economically and are compatible with the board level components that are needed to meet requirements. For buses that provide slots for component cards, use standard buses that are supported by multiple vendors providing compatible component cards.

5.2.3 Main Memory—Main memory is the storage warehouse of the computer where data and programs are stored for efficient processing. In the context of this section, main memory refers to cache and RAM. The main factor to consider in acquisition of a computer system is the quantity (in megabytes) of RAM. Other considerations are access speed, mounting design, and parity. Computer systems with too little memory run slowly, won’t load, and crash often. Mounting designs today generally provide for easily upgradeable Memory Modules. SDRAM (Synchronous Dynamic Random Access Memory) has long been a standard for memory, but more advanced designs such as DDR (Double Data Rate) and Rambus memory offer better speed and throughput and are rapidly gaining wide acceptance. Older architecture memory designs are generally slower and less efficient and should be avoided to the extent possible.

5.2.3.1 Cache is usually hard wired to the motherboard and has a faster access time than RAM. Computer system caches of 512 KB or larger are generally satisfactory.

5.2.3.2 RAM can often be on a separate memory board and is used to store the OS, applications that are running, and data files. The amount of RAM needed for a computer system can vary with the environment and the OS. Servers generally need about an order of magnitude more RAM than personal workstations. For personal workstations with a 16/32 bit operating system, 64 MB or more of RAM is recommended; for workstations with 32/64 bit operating systems, 128 MB or more is recommended. For servers, use the Network Operating System (NOS) guidelines based on the environment. The three major factors used to determine the amount of RAM for a server are number of user connections, number of processes running, and amount of hard drive space.

5.2.4 Input/Output (I/O) Interfaces—I/O interfaces allow the computing resource to move data between the “outside world” and the CPU and main memory. Operations like loading a program or file from a floppy or CD, sending and receiving information over the LAN or WAN, or sending a document to the printer to get a hardcopy use I/O interfaces. Quite often the information is sent to or received from a peripheral, which is discussed in the next section.
NOTE 1—Extended Data Out (EDO) DRAM was long a standard for mass-market memory, but Synchronous DRAM (SDRAM) is now the standard for currently installed machines. SDRAM is a memory architecture that incorporates many improvements over traditional DRAM technologies. SDRAM is a new technology that runs at the same clock speed as the microprocessor. The clock on the memory chip is coordinated with the clock of the CPU, so the timing of both the memory and the CPU are “in synch.” This reduces or eliminates wait states, and makes SDRAM significantly more efficient than Fast Page Mode (FPM) or even Extended Data Out (EDO) memory.

NOTE 2—Even more speed and throughput improvements are being realized with Double Data Rate (DDR) and Rambus Memory; selection of a memory architecture will need to be made according to a careful consideration of cost (particularly over the anticipated service life of a system) and performance considerations.

5.2.4.1 Use I/O interfaces that use open access standards, support open device connections, and are platform independent.

5.2.5 Peripherals—Peripherals provide data access, input, storage, and connectivity for a computing resource. The number of peripherals available on the commercial market continues to explode, generally driven by processor speeds, memory/storage capacities, and I/O speeds. Although there are many different types of peripherals, such as printers, facsimiles, modems, scanners, video cameras, microphones, speakers, and so forth, the main issue in specifying/procuring these items is the compatibility of their I/O interfaces with the computer (see 5.2.4) and application software. Apart from these compatibility issues, the major considerations for acquiring peripherals are cost and performance (which can include both speed and quality). A major category of peripherals is static storage devices. As distinguished from main memory (covered in 5.2.3), static storage devices retain data when the power is off. The remainder of this section will discuss storage devices. Use peripherals that support standard I/O interfaces and are platform independent.

5.2.5.1 Storage Device Standards—Storage refers to the capability to store information outside the central processor. For most computers, the predominant technology for storage has been magnetic disk and will remain so for the next few years.

</table>

NOTE 1—Fibre Channel (FC-PH) is emerging as a host-level interface standard for delivery of high I/O data transfers. FC-PH provides connections for workstation clustering, storage clustering and network-based storage concepts, parallel processing, load leveling, host-to-host or server-to-server communications, host- or server-to-mass storage communications, bulk data transfer, and multimedia. FC-PH is also being used as a system bus at the CPU and memory level as well as a way to cluster multiple systems similar to Non-Uniform Memory Access (NUMA). NUMA describes an architectural approach to clustering multiple systems such that distributed memory appears to the operating system as shared memory. This architectural approach allows a benefit to the user of a shared memory programming model with the scalability of a massively parallel processor’s (MPPs) distributed memory model. FC-PH currently provides up to 1.062 GigaBits Per Second (Gbps) bandwidth using optical fiber.

NOTE 2—FC-PH-based storage subsystems will be supported on mainframes; therefore, the Enterprise Systems Connection or ESCON-based systems will be phased out.

NOTE 3—The Upper Layer Protocol (ULP) over FC-PH from the mainframe will initially deploy as SCSI-2 or SCSI-3 and migrate quickly to Intelligent Peripheral Interface (IPI). IPI will be deployed on large servers before it will be deployed on mainframes. Note that IPI is a protocol only; SCSI is both a protocol and an interface. FC-PH is an interface that can support various ULPs.

NOTE 4—For servers and higher end personal workstations, SCSI is the predominant host-level interface for current disk and peripheral devices. As the demand for higher data transfer rates and expanded connectivity requirements increase, SCSI-2 and SCSI-3 over FC-PH in a PCI form factor will be the appropriate long-term direction.

NOTE 5—Enhanced IDE is the predominant peripheral interface for lower end personal workstations. SCSI is the current interface of choice for high-speed devices, such as high-capacity disk and tape drives and is the appropriate long-term direction for both the commodity level and high capacity devices.

NOTE 6—Personal Computer Memory Card International Association (PCMCIA) announced that PCMCIA cards are now referred to as PC Cards. The PC Card Standard defines a 68-pin interface between the peripheral card and the PC Card “socket” into which it gets inserted. It also defines three standard PC Card sizes, Type I, Type II and Type III. All PC Cards measure the same length and width, roughly the size of a credit card. Where they differ is in their thickness. Type I, the smallest form factor, often used for memory cards, measures 3.3 mm in thickness. Type II, available for those peripherals requiring taller component such as LAN cards and modems, measures 5 mm thick. Type III is the tallest form factor and measures 10.5 mm thick. Type III PC cards can support small rotating disks and other tall components.

NOTE 7—As mentioned under “Bus” (see 1.1.2), CardBus is a new standard introduced as an addendum to the PCMCIA PC Card standard. CardBus is a 32-bit bus-mastering card operating at 33 Mhz transferring data at up to 132 MBytes per second. (The 16-bit PC Card bus data rate is 20 MBytes per second.) Like PC Cards, CardBus uses the 68-pin interface but operates at 3.3 volts versus the 5 volts used by PC Cards. CardBus slots are backward compatible with PC Cards. Card sockets can support PC Cards only or CardBus cards only, but not a mixture of the two.

NOTE 8—Serial I/O refers to standard serial interfaces such as RS 232, 422, 423, and 449.

NOTE 9—Parallel I/O refers to standard parallel interfaces such as micro-Centronix.

NOTE 10—XIO is an emerging I/O solution based on Specialist’s S1 controller, and incorporating the high performance I/O processor and communication technology introduced in the RIO range. XIO is ideal for the 16-32 user system where sustaining high performance is essential.

NOTE 11—IEEE 1394, also known as “Firewire,” is a high speed serial I/O that supports data rates up to 400Mbps.
5.2.5.2 RAID Technology—Redundant Array of Independent Disks (RAID) technology protects from data loss by providing a level of redundancy immediately within an array. The array contains removable disk drive modules that are automatically rebuilt in the event of a device failure without causing the system to shut down. When RAID levels other than 0 are used, no downtime is required to replace a failed disk drive. Data is continuously available while reconstruction of the failed disk occurs in the background. Much of the benefit of RAID technology lies in its capability to off-load storage management overhead from the host system. To realize this benefit, RAID developers endow their array controllers with significant levels of intelligence. For instance, Adaptive RAID supports multiple RAID levels based on workload characteristics. Choose the RAID level based on your specific need.

5.3 System Configurations—The hardware component technologies mentioned in 5.2 can be configured in many different ways to accomplish different tasks and meet different requirements. This section examines some of the common configurations (Personal Workstations, Servers and Embedded Computers) with guidance on what component technologies to use for each configuration.

5.3.1 Personal Workstation—Personal Workstations (PW) are devices that contain at least one CPU (sometimes several) and provide a user interface, typically a GUI, as well as personal productivity tools, local data storage, and a flexible method for accessing and manipulating data. These PWs are commonly known as Personal Computers or PC’s, desktop computers, portables (laptops or notebooks), or workstations and use one of several bus architectures. Low-end PWs are used primarily to support the general office workplace. More powerful PWs are predominantly used in high-end computer applications such as Computer-Aided Design/Computer-Aided Manufacturing/Computer-Aided Engineering (CAD/CAM/CAE), application development, multimedia, and decision support data analysis presentation.

5.3.1.1 Also included in PWs are handheld computers—Personal Digital Assistants (PDAs), also referred to as Personal Information Managers (PIMs). Handhelds are computer systems that fit in a person’s hand and are extremely portable. Handheld systems also tend to have two types of input methods: pen or keyboard. The pen input can be used as digital ink, a mouse, or for handwriting recognition.

5.3.1.2 Combine components that provide flexible, scalable, and easy-to-use personal workstations that support the Client/Server model of computing, data access, and multimedia. Allow for an external communication device such as a modem or network interface card.

5.3.1.3 Table 9 provides a quick summary of the nominal specifications for Personal Workstation implementation.

5.3.2 Servers—Servers are computing resources that can be configured to support groups from small teams (work group

### TABLE 6 Storage Device Media

<td>4 mm DAT</td>
</tr>
<tr>
<td>DLT Tape</td>
</tr>
<tr>
<td>3490E cartridge tape</td>
</tr>
</tbody>
</table>

Note 1—8-mm helical tape is appropriate for backup and archive use; however, it is slow and unreliable for near-line storage solutions where frequent access is required. 4mm DAT offers a faster, more reliable solution to high-capacity and high-access applications.

Note 2—½-in. helical tape offers higher storage capacity than 4 mm or 8 mm; however, it is expensive, proprietary, and only Storage Technology supports it.

Note 3—3490E square cartridge ½-in. tape is predominantly a mainframe technology for off-line data storage.

Note 4—Higher capacity tape applies capacity multipliers of $2^X$ to $4^X$ to current technology. Gains are achieved through increased density factors as well as media length (number of media ft per unit).

Note 5—Flash Memory Storage devices are finding wide acceptance in Asia. They can hold as much as 128 MB of data in a keychain form factor that plugs into an available USB port.

Note 6—Smart cards are being used in Europe and Asia. Smart cards will be used predominantly as an intelligent storage media for providing services to individuals.

Note 7—the Digital Video Disk (DVD, also known as Digital Versatile Disk) allows for dual-sided as well as dual-layered implementations that will increase CD-ROM capacities significantly. In addition, transfer rates may improve to as high as 16 Mega Bits Per Second (Mbps).
servers) to entire ships (campus servers). Work group servers provide support, such as directory, file, print, and authentication services, in a LAN environment. Campus servers may augment and, for many new applications, replace traditional mainframes. Selecting systems that address and support features and services of both systems management and reliability, availability, and serviceability is important. Campus servers often implement RAID storage technology to provide services with high reliability and availability (see 5.2.5.2).

5.3.2.1 There are different types of servers, performing more specific functions. Some of these server types include: database servers, multimedia servers, data push server, applications server, optical disk servers, and mail servers. A brief description of these servers follows:

1. **Database Servers**—Large databases make extensive use of disk space and processor power and typically require their own dedicated database server hardware. Increasingly these database servers have more than one CPU and more than one network interface channel to keep up with the demands placed upon them by large numbers of simultaneous users.

2. **Multimedia Servers**—If an installation has a large archive of audio or video data, or if it intends to distribute audio or video data in real-time, it will require a multimedia data server. Archives of audio and video data require huge amounts of disk space. Moving this data over the network (typically through streaming audio or video services and protocols) is also resource intensive. Both requirements typically require the dedicated use of a multimedia server.

3. **Data Push Servers**—If an installation implements a data push mechanism for distributing information to internal and/or external desktops, it will have to host that push function on a data push server. Depending on the number and volume of channels being pushed, the data push server software may reside on hardware that is also performing other server functionality (typically the web server).

4. **Application Servers**—One option for centralizing system management and reducing total cost of ownership in a network environment is to run the actual application programs on a few high-powered application servers rather than on the desktop clients. This is a common approach in UNIX-based computing environments through the use of the X Windows graphical interface to open display and control windows on one system for an application running on another system. A new variation of this approach brings current Microsoft Windows applications to systems that are under-powered (old 286 or 386 CPU PCs) or that are not running the 16/32 bit based Windows operating system (UNIX workstations, Java Network Computers). This is made possible by running the applications on shared Windows NT/2000 application servers and just sending the user interface over the network to the user’s local system.

5. **Optical Disk Servers**—With the huge amounts of reference data available on CD ROM and the increasing availability of CD ROM writers for organizations to use to create their own archival data storage on CD ROM, there is a growing need to have multiple CD ROM disks online at once. A new class of hardware, the CD ROM Server, is a stand-alone network device that includes a large number of CD ROM drives which can be made available as shared disks to all users on a network.

6. **Mail Servers**—In an organization that has a number of networked PW clients, mail servers provide store and forward functions for electronic messages. These servers receive, store, and distribute electronic messages and require a large amount of storage, proportional to the number of e-mail accounts they carry. They also require numerous network connections and modem connections to receive and distribute messages from/to users and other organizations.

5.3.2.2 Evaluate servers for their interoperability, portability, reliability, availability, serviceability, and scalability. The capability to easily upgrade processor performance or to add additional processors, disk storage, and communications supports extend the life of the platform and enhances the return on investment. Use hardware components that are standards-based, primarily those that are compatible with interface bus standards. Select scalable servers that can increase performance by adding components and by supporting standards-based network protocols. Through the use of a multiprocessing architecture, hardware should be scalable and should enable parallel processing.

5.3.3 **Embedded Computers**—When readily available computers do not meet the requirements, components must be integrated to form a system. This often involves a design of board level components to perform the necessary functions. The major design consideration is the selection of a back plane

bus that will allow all of the components to communicate with each other. This decision can impact dramatically the cost, both in the development and the logistics support of the system. Considerations in determining the bus include availability of components and existing systems bus architectures (to reduce the logistics support costs). Commercially available components should be considered first before custom designing and building the components. When designing embedded computer systems, use industry standard buses and standard components to the maximum extent possible.

6. Cable Plant

6.1 The cable plant includes copper cable and fiber optic cable. Fiber optic cable is the solid media preferred for its current high-capacity (100’s of Mbps), future bandwidth potential (Gbps to Tbps), reliability, reduced susceptibility to Electromagnetic Interference (EMI), and security. (Although fiber cannot be made completely secure without encryption or proper physical protection, it cannot be “tapped” without physical manipulation.)

6.2 Fiber optic cable is required to support voice and high-speed data. Fiber optic cable is recommended in other areas where feasible. If cost limits its use, then fiber optic cable should be run at least in the backbone of the network and to areas, which are already wired. However, it is recognized when linking distant, or otherwise limited-access areas, that can be easily, and inexpensively, rewired with fiber when appropriate. If copper is used, select only properly terminated and tested Category 5 (“Cat 5”) cable for cable from the telecommunications closet to the desktop. (Unshielded Twisted Pair (UTP) Cat 5 is the copper standard for data rates up to 155 Mbps.) Thin-wire coax, thick-wire coax, RS-232/422, Category 3 and “telephone” wire should be avoided—the minor cost savings is not usually justifiable because of limited data rates and degraded interoperability. (Allowable exceptions are recognized when linking distant, or otherwise limited-access areas, which are already wired.)

6.4 Definitions:

6.4.1 Trunk Cable—A trunk cable is a cable that connects two main interconnection boxes or patch panels. It is used to provide connectivity between the service areas of the cable plant.

6.4.2 Local Cable—A local cable is a cable that connects a main interconnection box or patch panel to user system equipment or a local breakout box.

6.4.3 System Specific Cable—A system specific cable directly connects two pieces of user system equipment, independent of the cable plant. A system specific cable is typically used to connect equipment within the same service area of the cable plant.

6.4.4 Drop Cable—A drop cable is a system specific cable between a ready movable piece of user system equipment, such as a PC or printer, and the local breakout box in the area. A drop cable is not considered to be part of the cable plant.

6.5 Fiber Optic Cable—Fiber optic cable is the preferred media for all network applications due to its growth potential. (In shipboard and other high Electromagnetic Interference (EMI) environments, fiber optic cable is critical in eliminating the effects of noise.) The backbone network must use fiber optic cabling, as part of the Fiber Optic Cable Plant (FOCP)—twisted pair (shielded or unshielded) or coaxial cable should not be used. Where possible, multimode graded index fiber with a 62.5-micrometre (µm) core/125 µm cladding should be used. Due to the low relative marginal cost, single-mode fiber (8 µm core/125 µm cladding) should be provided in at least the backbone FOCP and preferably to major junction points.

6.5.1 Multimode fiber (62.5 µm) is easier to terminate and test, especially in the field. However, there are distance and bandwidth limitations that cannot be overcome and single-mode fiber must be used. (Multimode fiber can support rates of up to 155 Megabits per second (Mbps) at distances up to 2 kilometres (km). It can only support 622 Mbps for hundreds of feet. Single-mode fiber (8 µm), however, can easily support units of Gigabits per second (Gbps) at up to 30 kms. Further, it can support multiple wavelengths, each operating at units of Gbps. Thus today’s single-mode fiber can support tens of Gbps.

(A) Varies widely based upon system requirements.

Note 1—Although VME bus is more popular and offers a wider variety of vendor products, VXI bus offers a greater degree of standardization and therefore a greater degree of interoperability among vendors’ products. These are the buses of choice for embedded systems.

Note 2—As the popularity of PCI bus rises and the number of available products increases, PCI becomes a more desirable architecture for embedded systems.
for tens of kilometres. Laboratory tests have shown this limit to be at least 2 orders of magnitude higher, namely Terabits per second (Tbps).

6.5.2 Unshielded Twisted Pair (UTP)—Category 5 UTP cable may be used only for the cabling between the appliance and the network edge device or between the workstation and other network equipment under certain conditions. Shielded Twisted Pair (STP) cable should not be used. The following factors should be taken into consideration when using Category 5 UTP cable:

6.5.2.1 Mission criticality of the application (The UTP copper cable may exhibit a lower availability than fiber due to EMI problems.)

6.5.2.2 Bandwidth or signaling rate (UTP may be used for short runs of 100BaseT, but should not be used at higher data rates or for long runs.)

6.5.2.3 Security level (UTP is easy to tap if not run in conduit.)

6.5.2.4 Length of cable run (UTP should be limited to intra-compartment runs.)

6.5.2.5 Installation factors (UTP requires exceptional care during installation, and should be thoroughly tested.)

6.5.2.6 Environmental Factors—EMI (UTP is subject to interference from radar and nearby high-powered equipment.)

6.5.3 In ship and marine environments, UTP cable should meet general flammability, smoke, acid gas generation, halogen content, and toxicity index requirements. Further, UTP should be limited in critical systems to due to EMI, shock, and vibrations (RJ-45 plastic connectors for UTP are not designed to withstand significant shock loads and may crack or disconnect under long-term vibration conditions).

6.5.4 Legacy Copper-Media Networks—For installations with copper-based legacy systems, it is recommended that those systems be selectively upgraded to fully integrate users of the backbone network based on capability requirements and funding availability. In ship and marine environments where upgrade funding availability or system requirements cannot support the decision to upgrade the system, connectivity to the ship’s backbone network can be accomplished at either the backbone or workgroup switch, providing that those devices can support the legacy network protocols. In such a configuration, the backbone network switch acts as a gateway between the legacy system and the rest of the backbone. If some limited funding for system upgrade is available, and such upgrades suit the needs of the ship, a lower cost interim upgrade would be to replace the legacy copper links with fiber optic links, and integrate those links into the ship’s FOCP. This interim physical integration will simplify the further upgrade from a separate legacy system to an integrated network application.

6.5 Patch Panels, Interconnection Boxes, and Connectors:

6.5.1 FOCP Interconnection Boxes—FOCP interconnection boxes and patch panels should hold a minimum of 48 connector pairs. Interconnection boxes should be sized to accommodate all of the fibers (allocated, spare, and growth) that enter the box.

6.5.2 Local Breakout Boxes—Local breakout boxes may be used to provide additional flexibility in locating workstations or easily moved equipment. The interconnection box should completely enclose the fiber terminations. Local breakout boxes should not be used as a substitute for rack-mounted patch panels for the interconnection of rack-mounted equipment.

6.6.3 Location of Tx-Rx Pairs and Optical Crossover—In FOCP Interconnection Boxes, local breakout boxes, and in rack-mounted patch panels, the pair of ST connectors associated with one full-duplex optical circuit should be located in a vertical line, one above the other, with the transmit (Tx) connector above the receive (Rx) connector. In a complete optical link, there must be one (or an odd number of) crossover(s) in order to connect the optical transmitter at one end to the optical receiver at the other end, and vice versa.

6.7 Connectors

6.7.1 Fiber Optic Cable:

6.7.1.1 ST-type—ST-type connectors were, until recently, the standard for all multimode connections. In commercial applications, SC is rapidly becoming the standard. It is becoming hard to find host network interface cards with ST connectors.

6.7.1.2 SC-type—SC-type connectors are becoming the industry standard for both host network interface cards and backbone connections. While this is acceptable for multi-mode fiber, it has debatable merit for single-mode fiber. (Pros: more common connector, easier to insert/remove; Cons: can more easily confuse multi-mode with single-mode fiber, if single-mode transmitter accidentally plugged into multi-mode receiver, the receiver could be permanently damaged.)

6.7.1.3 FCPC-type—FCPC-type connectors are the standard for single-mode fiber. Many equipment vendors, however, are beginning to use SC-type connectors. Because the risk of accidentally switching multi-mode and single-mode connections exists when the same connector is used for both, it is recommended that FCPC-type be used for single-mode fiber (see discussion in the previous paragraph).

6.7.1.4 MIC-type—MIC-type connectors are not recommended for use within the backbone network. However, if MIC-type connectors are the only available option, it is recommended that a MIC-ST jumper cable be fabricated to allow the MIC connector at the equipment interface, but with an ST connector for connection to the FOCP or rack-mounted patch panel. MIC connectors should not be used within FOCP interconnection boxes.

6.7.1.5 Heavy-Duty Multiple Terminus—Heavy-duty multiple terminus connectors are recommended for equipment interfaces that require a rugged interface that is easily disconnected and reconnected.

6.7.1.6 Mechanical Splice—Mechanical splices are recommended only for those applications requiring higher optical performance than is available with ST-type connectors. Mechanical splices may be used in interconnection boxes, and may also be used inside rack-mounted patch panels where needed for higher optical performance.

6.7.2 Copper Cable:

6.7.2.1 RJ-45 Connectors—Category 5 cable specifications limit the connector type to RJ-45. However there are a number of pin-out standards from which to choose. Because ISDN also specifies the use of RJ-45, the ISDN pin-out specification will
be used: ANSI/EIA/TIA-568-1991 Standard, Commercial Building Telecommunications Wiring. This variant is designated EIA/TIA T568A (also called ISDN, previously called EIA).

6.7.3 Ship and Marine Environment—In ship and marine environments, ST-type connectors are recommended for all light-duty multi-mode fiber applications. ST-type connectors may be used as the interface to equipment if sufficient cable strain-relief and protection are provided. Failure to provide sufficient strain relief and protection will result in connector breakage or failure.

6.7.3.1 Until such time as SC-type connectors are evaluated against shock, vibration, and wear, they are not recommended for use within the backbone network. However, if SC-type connectors are the only available option associated with the network equipment, it is recommended that an SC-ST jumper cable be fabricated to allow the SC connector at the equipment interface with an ST connector for connection to the FOCP or the rack-mounted patch panel. SC connectors should not be used within FOCP interconnection boxes.

6.8 Topology, Security, and Integrated Cabling:

6.8.1 Basic Topology—The recommended physical topology is a mesh, as opposed to a ring or star configuration. If a logical ring or star topology is required for near-term cost reasons, the physical mesh cable plant infrastructure can be configured to provide the required logical topology. The mesh physical architecture will support the future expansion or upgrade to a full mesh logical topology.

6.8.2 Network Node Locations—Node locations should be selected based on the concentrations of current and planned network users. Nodes should be located in secure areas, to preclude unauthorized access to the equipment. Nodes should also be located in temperature controlled compartments, to optimize equipment reliability. Note that there is a trade-off between the number of nodes and the total quantity of local cable required to connect users. These two parameters should be considered in conjunction with the system requirements for survivability when determining the appropriate number of nodes.

6.8.2.1 Users should be connected to nodes within the same fire zone for survivability. Also, the number of nodes installed should be selected to provide maximum coverage of the ship’s fire zones, while minimizing the total network cost.

6.8.3 Patch Panel and Interconnection Box Locations—Main interconnection boxes or patch panels should be collocated with the network nodes. For maximum installation and connection flexibility, it is recommended that the patch panels be installed in the same rack as the network node equipment. These rack-mounted patch panels can also be used to provide a convenient means of interconnecting equipment within the same rack, and to provide a simplified disconnect point in the event that racks must be moved.

6.8.3.1 For racks containing connection-intensive network devices, the use of a rack-mounted patch panel should be considered to serve as the interconnection box for that zone.

6.8.4 Trunk Cable Routing—In general, trunk cables should be routed along diverse physical paths to ensure a survivable FOCP. The degree of redundant/fail-over equipment is cost-driven but with a proper FOCP mesh, outages can be quickly restored using alternate cable paths.

6.8.4.1 Trunk cables should be routed to provide survivable signal paths between interconnection boxes. In general, each trunk cable should have an identical redundant cable following a separate route between the two interconnection boxes. In addition, the cables should be routed on opposite sides of the ship, with at least two decks separating them vertically.

6.8.5 Local Cable Distribution—If a single user has multiple local cables for redundancy or survivability, those local cables should be routed to two different interconnection boxes, and should be separated within 60 ft of the equipment.

6.8.6 Network Fiber Allocations:

6.8.6.1 Inter-node—Fibers should be allocated for all inter-node connections. The level of inter-node connectivity should be determined based on current technical requirements, future projections of requirements, and overall program cost constraints. In general, it is desirable to include sufficient fiber in the FOCP to allow for full inter-node connectivity in a mesh topology. Any interim logical configurations, such as rings or stars, should also be considered when determining fiber requirements.

6.8.6.2 Redundancy—Redundant fibers in survivable separated trunk cables should be provided for each active and spare user system fiber. This is particularly critical in ship and marine environments.

6.8.6.3 Spares—Spare fibers should be provided on a 100 % basis; that is, each actively used fiber should have an assigned spare. This is particularly critical in ship and marine environments.

7. Wireless Networking

7.1 The establishment of standards such as IEEE 802.11 has created the ability of computers to communicate via network protocols without physical wiring. Commonly known as wireless Local Area Networks, this innovation provides practical interconnectivity without the investment or labor required to establish physical media.

7.2 Wireless networks operate on a range of frequencies and bandwidths, with newer systems functioning at 2.4 GHz frequencies and with a bandwidth of approximately 11 Mbs. These networks operate at a range of up to 90 m indoors, and out of doors can operate up to 300 m. Actual communication methods may vary, however, and care must be exercised to ensure that equipment from various vendors is compatible.

7.3 Workstations equipped with compatible wireless networking cards can operate in a peer-to-peer fashion, but in a larger installation a more reasonable design would be to establish distinct Wireless Access Point (WAP) devices that connect directly to the cable plant and act as gateways to the physically wired network and attached servers. In this scenario, wireless workstations may be moved from location to location within a ship and connect to the network wherever a WAP is established. Laptops and PDAs are particularly well suited to support WAP installations, due to their inherent mobility.

7.4 The ability of a wireless-configured device to easily connect to another wireless device or WAP also highlights one of the disadvantages of wireless networks. Security of operating data, services and systems can be seriously compromised in
8. Ship and Marine Facility Requirements

8.1 Racks—Ship and marine networking equipment should never be installed by setting them upon desks, tables, filing cabinets, etc. Small equipment can be bulkhead-mounted or hung from the overhead; however, the preferable technique for ship and marine installation of standard information processing equipment is in racks.

8.1.1 Suitable racks can be obtained from a number of vendors. However, heavy duty, industrial grade or ruggedized racks should be used, not lightweight racks intended for shore-based office environments. Standard rack widths are 19 in. and 24 in. Nearly all typical networking equipment is designed to fit into 19-in. wide racks. (Note that these are mounting widths; the overall external width of a 19-in. rack is about 24 in., and the outside width of a 24-in. rack is about 30 in.)

8.1.2 Standard 19-in. racks come in several depths, typically 17 in., 24 in., 29 in., and 36 in.. When deciding on the depth of a rack, remember to allow enough depth for recessing equipment that have front-access cabling, and to allow air exhaust space for equipment with rear-facing fans. Many pieces of networking equipment have modular assemblies that are removed from the front, and the cables attach to these assemblies from the front. This requires that the unit be recessed at least 4 in. to allow a reasonable cable bending radius. (For units that have rear-accessible modules, it is often desirable to mount them in backwards for easier access to removable modules.)

8.1.3 If there is sufficient space in the compartment to mount the racks away from the bulkhead for both front and rear access, a sufficiently deep rack will permit electronics units and fiber patch panels to be placed back-to-back at the same vertical level within the rack.

8.1.4 Consider cable entry when ordering racks. If the rack is to be located on a raised false deck, then the cabling can enter from the bottom. Otherwise the cable should enter the rack from the lower half of the rear panel. For all cable entrances, a minimum of three in. of slack should be provided to allow for movement of the rack under shock and vibration. There should also be a minimum length of 18 in. between the last cable support and the cable’s entrance to the equipment.

8.1.5 Racks should be ordered with removable, but lockable, side, front and rear panels for maximum equipment accessibility. Note that the location of louvers in rack panels depends upon the cooling method that is used (see below).

8.1.6 The location of equipment within racks is a trade-off among the often-conflicting parameters of accessibility, weight, and cooling. Heavy equipment should be located low in the rack for stability and ease of removing. Equipment that requires reading of displays, LEDs, or patching should be located at eye level. Heat-dissipation equipment should be located near the air exhaust, not near the cold air inlet, to avoid pre-heating the air flowing over the rest of the equipment.

8.1.7 Heavy equipment should be mounted using front-to-rear angle brackets or slide trays to simplify installation and removal, and to avoid the need to carry the weight of the equipment on the front panel screws.

8.1.8 Rack Cooling—Racks that contain equipment whose total power dissipation is more than 100 W should be provided with rack-mounted blowers or fans to augment any cooling that might be provided by fans inside the equipment.

8.1.8.1 The ft³/min (CFM) rating of the rack blower/fans can be estimated from the following equation:

\[
CFM = 4P/T
\]

where:

\[
CFM = \text{airflow, ft}^3/\text{min},
\]

\[
P = \text{total rack power dissipation, W, and}
\]

\[
T = \text{temperature rise (inlet to outlet), } ^\circ\text{F.}
\]

For example, a rack with 1000 W of electronics will need a 400-CFM blower to limit the temperature rise to 10°F.

8.1.8.2 Since heated air tends to rise, the airflow from fans or blowers should be bottom-to-top. This means placing a blower at the bottom of the rack, or an exhaust fan at the top of the rack. In either case, a washable air filter should be placed at the air entry point. Note that the blower, as opposed to the exhaust fan, has the added advantage of putting a positive pressure within the rack to keep out dust and dirt from unfiltered air entry.

8.1.8.3 If a blower is placed at the bottom of the rack, then the rear or side panels, or both, should have louvers near the top for exhaust air to exit. Do not use fully louvered panels that would short circuit the air flow. If exhaust fans are used, then the doors and panels should have no louvers; the cold air enters from the air filter near the bottom and the warm air exits via the top-mounted exhaust fan.

8.1.9 Shock Isolation—Ship and marine equipment racks should not be hard-mounted to deck foundations, but should be shock isolated via coil springs or other acceptable isolation mechanisms. Tall racks (over 1.5 m tall) should also have shock-isolated anti-sway mounting from the top of the rack to the bulkhead or to the overhead (see 8.5.5).

8.2 Line Conditioning and UPS—Ship and marine ac power is often unreliable, noisy, and subject to over-voltage and under voltage conditions that can seriously damage networking equipment. Network equipment should never be connected directly to shipboard power without the protection of a line conditioner and an uninterruptible power supply (UPS). (Printers need not be connected to UPS.)

8.2.1 Line conditioners protect against over/under voltage conditions, and provide some degree of noise suppression, but do not protect against total loss of power. UPSs provide over/under voltage protection, noise suppression, and supply ac power (generated from dc batteries within the UPS) for a limited time. (The loss-of-power protection interval varies with the size of the UPS batteries, but should be designed to operate for a minimum of 30 min when the UPS is operated at the recommended 50 % rated load.)
8.2.2 Unlike shore-based ac distribution systems, ship and marine power uses an ungrounded (floating) neutral. If ordinary line conditioners or UPSs are connected to shipboard power, the grounded neutral will cause a ground-fault indication. Line conditioners and UPSs with floating neutral can be obtained, but they must be special-ordered for ship and marine service.

8.3 Electrical System Interfaces:

8.3.1 Electric Load Analysis—Prior to installation, an electrical load analysis should be performed to calculate the electrical system impact associated with the new equipment, taking into consideration any removed equipment as well.

8.3.2 Local Distribution—if adequate electrical distribution is not available to supply the new loads, install additional equipment and cable as required. If the existing electrical distribution system is modified, circuit breakers and cables should be examined for adequacy and modified or replaced as necessary to support the new loads.

8.3.3 Bonding and Grounding—Secure electrical information processing equipment and cables should be bonded and grounded.

8.3.4 Power Source for Backbone Switches—Backbone switches should be supplied ac power from two independent power sources via an automatic power bus transfer system.

8.4 Air Conditioning—Prior to installation, the ability of the existing ship’s air conditioning system (High Volume Air Conditioning (HV AC) system) to support the equipment installations in each compartment on the ship must be verified.

8.5 Special Considerations for Ship and Marine Critical Systems:

8.5.1 Shock Equipment shall meet grade “A” shock requirements. Equipment shall operate before, during and after shock conditions resulting from high impact shock testing of hardware, mounting rack, and shock mounting devices. For critical signals that cannot accept momentary disruption of a circuit, multi-mode fiber is preferred over single-mode fiber because multi-mode fiber connectors withstand shock more readily than single-mode connectors.

8.5.2 Humidity—Using commercially available hardware in environments with condensing 100% relative humidity can lead to shorting of printed circuit cards which are normally not conformally coated in commercial equipment. One solution to this problem is the use of specially treated equipment rooms (node rooms) or controlled spaces where highly reliable air conditioning is always available.

8.5.3 Temperature—Most electronic equipment is designed to temperature ranges of 0 to 30, 40, or 50°C. Ship and marine operation outside of this range can cause failure or improper operation of LED displays, hard drives, and CD-ROM drives at the low temperature extremes, and power supplies and other electronics at the higher temperature extremes. The concept noted in the previous paragraph of air-conditioned node rooms can be used to solve this problem. Temperature testing shall be conducted with the equipment operational in a controlled environment of 0 to 55°C.

8.5.4 Magnetic Field—The high magnetic fields caused by ship degaussing can disturb the displays on CRT screens. If critical information needs to be read during degaussing, consider the use of flat-panel displays instead of CRT displays.

8.5.5 Vibration Equipment shall be subjected to endurance testing at fixed frequencies based upon the critical frequencies determined from the vibration response testing. When vibration response investigation does not identify any critical frequencies, testing shall be conducted at the maximum vibration frequency of 100 Hz and 0.076 mm vibration amplitude.

8.5.6 Electromagnetic Susceptibility—The equipment shall not be susceptible to electromagnetic emission in the room or area in which it is installed.

8.5.7 Fungus/mold—The equipment shall not support fungal or mold growth.

8.5.8 Salt Fog—Equipment shall be tested to withstand salt fog when used in ship and marine locations that are susceptible to salt fog conditions.

Standard Guide for
Ordering Low Voltage (1000 VAC or Less) Alternating Current Electric Motors for Shipboard Service—Up to and Including Motors of 500 Horsepower

This standard is issued under the fixed designation F 2361; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers the required basic ordering information for low voltage (1000 VAC or less) general-purpose, commercial, universal, small and medium sized alternating current electric motors for shipboard use, up to and including motors of 500 hp.

1.2 The electric motors covered by this guide are general-purpose (GP) motors intended to drive common shipboard mechanical machinery such as fans, blowers, centrifugal and screw pumps.

1.3 This guide is not intended to be used to order special-purpose (SP) motors or definite-purpose motors (for example, cryogenic service) or motors for use in hazardous (classified) locations as defined by the National Electrical Code (NFPA 70).

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 closed-coupled—a special design where the motor features a face mounting flange that the pump casing mounts to, and a motor shaft extension on which the pump impeller is mounted.

3.1.2 dripproof—a machine enclosure that allows the motor to be cooled by ambient air having ventilation openings that allow operation when drops of liquid or solid particles strike the enclosure at any angle from zero to 15°.

3.1.3 drive method—the method of driving the equipment, such as direct, belt, gearbox, or chain.

3.1.4 efficiency classes—standard efficiency classes established by NEMA based on motor performance.

3.1.5 end shield—a machined flange or base which have rabbets and bolt holes for mounting equipment to the motor or for overhanging the motor on a driven machine.

3.1.6 frame size—standard sizes established by NEMA based on motor power and speed.

3.1.7 mounting arrangement—the installed operating position of the motor, such as horizontal, vertical shaft up, or vertical shaft down.

3.1.8 multi-speed—a motor that can operate at more than one speed, typically at two or three speeds.

3.1.9 NEMA design classes—design classifications designated by NEMA (See NEMA Standard MG-1) for motors that provides information to the end user on characteristics such as motor starting, torque, voltage, and so forth.

3 Available from Institute of Electrical and Electronics Engineers, Inc. (IEEE), 445 Hoes Ln., P.O. Box 1331, Piscataway, NJ 08854-1331
4 Available from National Electrical Manufacturers Association (NEMA), 1300 N. 17th St., Suite 1847, Rosslyn, VA 22209.
5 Available from National Fire Protection Association (NFPA), 1 Batterymarch Park, Quincy, MA 02269-9101.
3.1.10 **NEMA insulation classes**—NEMA system that classifies motor insulation systems by their ability to withstand a specified temperature for a specified length of time with minimum deterioration.

3.1.11 **polyphase medium motors**—motors which have windings so arranged to accept to polyphase voltage sources.

3.1.12 **service factor**—service factor for an ac motor is a multiplier, which when applied to the rated horsepower, indicates a permissible horsepower loading which may be carried under the conditions specified for the service factor.

3.1.13 **single-phase fractional horsepower motors**—motors with ratings up to 1 hp which use single-phase power.

3.1.14 **single-phase integral horsepower motors**—motors with ratings of 1 hp up to and including 10 hp, which normally use single-phase power but at the upper end of their specified range may also utilize polyphase power.

3.1.15 **slip**—the difference between synchronous speed and full load speed. Normal slip is less than 5%.

3.1.16 **speed**—the number of revolutions per minute (r/min) at which an induction motor operates, which is dependent upon the input power, frequency, and the number of magnetic poles in the machine.

3.1.17 **temperature, ambient**—the temperature of the air surrounding the machine.

3.1.18 **temperature rise**—the difference between the hot spot temperature and the ambient temperature times a constant (see NEMA MG-1).

3.1.19 **totally-enclosed air over (TEAO)**—an enclosure similar to a TEFC except the cooling air is provided by a fan that is not part of the motor.

3.1.20 **totally-enclosed fan-cooled (TEFC)**—a totally-enclosed machine equipped for exterior cooling by means of a fan or fans integral with the machine but external to the enclosed parts.

3.1.21 **totally-enclosed non-ventilated (TENV)**—a machine enclosed to prevent the free exchange of air between the inside and outside of the case, but not sufficiently enclosed to be airtight.

3.1.22 **totally-enclosed water-air cooled (TEWAC)**—a totally-enclosed machine with integral water-to-air heat exchanger and internal fans to provide closed-loop cooling of the windings.

3.1.23 **universal motors**—typically small motors, which can operate on ac or dc current, or both.

3.1.24 **variable speed drive (VSD)**—a method used to permit an operator to vary the speed of a motor.

3.1.25 **weather protected**—a machine with ventilating passages so constructed as to minimize the entrance of rain, snow and airborne particles to the electrical components.

### 4. General Requirements for Electric Motor Ordering

4.1 **Electric Motor Ordering Requirements:**

4.1.1 With each electric motor ordered for marine service, provide the following, to the greatest extent practicable:

4.1.1.1 **Electrical Input**—Voltage, phases and frequency.

4.1.1.2 **Speed (Synchronous or Full Load)**—r/min.

4.1.1.3 **Power**—The horsepower of the motor must be stated as a standard NEMA rating. At a minimum, consideration should be given to the needed starting torque, capability to accelerate the load to full running speed and maximum overload.

4.1.1.4 **Enclosure**—Select in accordance with IEEE Standard 45. DP or TEFC are normally specified for below deck applications and WP for above deck applications.

4.1.1.5 **Duty Cycle**—Continuous duty is normally specified since it demands operation at an essentially constant load for an indefinitely long time. If intermittent or varying duty cycles are required, special motor selection criteria will apply.

4.1.1.6 **Ambient Temperature**—Standard motors are designed for 400°C ambient. If a higher ambient is required, this will reduce the service factor or reduce the motor rating thus requiring a larger size motor.

4.1.1.7 **Insulation Class**.

4.1.1.8 **Design Class**—NEMA designated design class.

4.1.1.9 **Service Factor (SF)**.

4.1.1.10 **Drive Method**.

4.1.1.11 **Mounting Arrangement**—If vertical, specify with or without feet.

4.1.1.12 **Mounting Flange (End Shield):**

   1. **C-face**
   2. **D-flange**
   3. **P-base**

4.1.1.13 **Rotation**—The rotation of the motor must be specified as clockwise, counter-clockwise or reversible.

4.1.1.14 **Conduit Box Location**—View from the non-shaft end of the motor:

   1. **Right (standard)**—F1
   2. **Left**—F2

4.1.1.15 **Closed-coupled**—Specify when the motor will mount the pump on a flange and the motor shaft mounts the pump impeller.

4.1.1.16 **Efficiency**—If compliance with the Energy Policy Act of 1992 is necessary, it should be stated that motors shall be furnished with a nominal efficiency as defined in Table 12-10, NEMA MG-1.

4.1.1.17 **Special Requirements**—This shall include, but not be limited to, space heaters, temperature protection, additional

regulatory or classification society requirements. Specific specification sections and paragraphs must be cited.

4.2 Other Requirements:

4.2.1 Marine Service—Each motor specified for installation on board ship shall as a minimum comply with the requirements of IEEE Standard 45.

4.2.2 General Testing—Unless otherwise stated, all motors shall be tested in accordance with the requirements of IEEE Standard 112.

4.3 Electric Motor Ordering Checklist:

4.3.1 It is recommended that the minimum information shown in Table 1 be provided to the supplier when ordering an electric motor for marine service.

Standard Specification for Temperature Monitoring Equipment

This standard is issued under the fixed designation F 2362; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the requirements for equipment intended to provide control input and monitoring of temperatures in general applications. Equipment described in this specification includes temperature indicators, signal conditioners and power supplies, and temperature sensors such as thermocouples and resistance temperature element assemblies.

1.2 Special requirements for Naval shipboard applications are included in the Supplementary Requirements section.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:

D 3951 Practice for Commercial Packaging
E 344 Terminology Relating to Thermometry and Hydrometry

3. Terminology

3.1 Definitions—Definitions of terminology shall be in accordance with Terminology E 344.

4. Classification

4.1 General—Temperature measuring devices are generally classified as either temperature sensors or thermometers. Thermometers are not covered by this specification. Temperature sensors are classified by design and construction. Sensors may also be classified by the manner of response, basically mechanical or electrical, to a change in temperature. Mechanical response is characterized by some mechanical action as temperature changes. Electrical response is characterized by the production or change of an electrical signal or property as temperature changes. The following describes the most common types of sensors:

4.2 Thermocouples—Thermocouples are constructed in a variety of designs to provide measurement of direct or differential temperature. Thermocouples are commonly installed using a thermowell which protects the thermocouple but also delays the rapid response time characteristic of thermocouples.

4.2.1 Principle of Operation—Most thermocouples utilize two wires fabricated from dissimilar metals joined at one end to form a measuring junction that is exposed to the process medium being measured. The other ends of the wires are usually terminated at a measuring instrument which forms a reference junction. When the two junctions are exposed to different temperatures, electrical current will flow through the circuit (Seebeck Effect). The measurement of millivoltage resulting from the current is proportional to the temperature being sensed.

4.2.2 Types of Thermocouples—Thermocouples can be divided into functional classes by materials and therefore, temperature ranges. The three classes are base metal, noble metal, and refractory metal. Although many types are commonly used in industrial applications, the Instrument Society of America (ISA) has assigned letter designations to seven types. By convention, the practice of using a slash mark to separate the materials of each thermocouple wire is widely accepted. Likewise, the order in which the materials appear also denotes polarity of the wires; positive/negative when the measuring junction is at a higher temperature than the reference junction. The following are examples of typical thermocouples:

4.3 Resistance Temperature Measuring Devices—Resistance thermometers measure changes in temperature based on changes in resistance of the sensor element exposed to the temperature. Two common types are resistance temperature detectors which have metal sensor elements and thermistors which have semiconductor sensor elements.
4.3.1 Resistance Temperature Detectors (RTDs)—An RTD consists of a sensor which uses a metal wire or fiber which responds to changes in temperature by changing its resistance. The sensor is connected to a readout via a bridge circuit or other means of translating the resistance to a temperature value.

4.3.1.1 Types of RTDs—RTD designs include averaging RTDs, annular RTDs, and combination RTD-thermocouples. Averaging RTDs are characterized by a long resistance element. Annular RTDs have sensors that are designed to provide a tight fit within the inner walls of thermowells. Combination RTD-thermocouples have both an RTD and a thermocouple housed in the same sheath.

4.3.2 Thermistors—Thermistors are made of solid semiconductor materials, usually complex metal oxides, that have a high coefficient of resistance. Thermistors are available with positive and negative temperature coefficients of resistance and are usually designated PTC and NTC thermistors, respectively. The temperature range for typical thermistors is 100 to 300°C (212 to 572°F).

4.3.2.1 Types of Thermistors—Thermistors are classified by the configuration of the semiconductor material. Common types are the bead, disc, washer, and rod thermistors. Leads are attached to semiconductor materials, except where metal plated faces are used for contact to complete the circuit.

5. Ordering Information

5.1 The purchaser should provide the manufacturer with all of the pertinent application data outlined in the acquisition requirements.

5.2 Acquisition Requirements—Acquisition documents should specify the following:

5.2.1 Title, number and date of this specification,
5.2.2 Classification required,
5.2.3 Quantity of units required,
5.2.4 Type of enclosure mounting,
5.2.5 Power requirements,
5.2.6 Equipment temperature ranges,
5.2.7 Size or weight limitations,
5.2.8 Disposition of qualification test samples,
5.2.9 Product marking requirements, and
5.2.10 Special preservation, packaging, packing and marking requirements.

6. Materials and Manufacture

6.1 Temperature Sensors—The materials for all wetted parts shall be selected for long term compatibility with the process medium.

7. Physical Properties

7.1 Description—The equipment specified herein in conjunction with the thermocouples or resistance temperature measuring elements comprise a temperature instrument. The temperature monitoring equipment may consist of the following units and may be built integrally together and housed in the same enclosure:

7.1.1 Signal Conditioner—The signal conditioner shall convert the sensing element output to a continuous linear analog signal directly proportional to temperature.

7.1.2 Power Supply—The power supply shall provide excitation energy to the signal conditioner and sensor.

7.1.3 Test Device—A test device shall be furnished to provide a calibrated test signal used for calibrating the equipment.

7.2 Size and Weight Considerations—A dimensional outline of the temperature monitoring equipment showing overall and principle dimensions in sufficient detail to establish space requirements in all directions necessary for installation and servicing will greatly assist proper selection. In many applications weight is a critical limitation.

7.3 General Features—Requirements for general features shall be specified. General features consist of the following:

7.3.1 Output,
7.3.2 Equipment range,
7.3.3 Adjustments,
7.3.4 Failsafe output,
7.3.5 Isolation,
7.3.6 Enclosure,
7.3.7 Power supply requirements, and
7.3.8 Cable entrance and connection.

8. Performance Requirements

8.1 Service Life—The purchaser may have a minimum specified service life requirement. Critical service life requirements shall be specified in the acquisition requirements.

8.2 Performance Considerations—Certain performance characteristics may be deemed critical to the intended or desired function of temperature monitoring equipment. Performance tolerances are usually expressed in percent of equipment span. The following performance characteristics and environmental exposures should be tailored to each purchaser’s intended application:

8.2.1 Accuracy,
8.2.2 Repeatability,
8.2.3 Threshold and deadband,
8.2.4 Ripple,
8.2.5 Warm-up time,
8.2.6 Input resistance,
8.2.7 Supply voltage or frequency, or both,
8.2.8 Temperature error,
8.2.9 Response time,
8.2.10 Temperature,
8.2.11 Insulation resistance,
8.2.12 Vibration, and
8.2.13 Shock.

9. Workmanship, Finish and Appearance

9.1 Finish and Appearance—Any special surface finish and appearance requirements shall be specified in the acquisition requirements.

10. Number of Tests and Retests

10.1 Test Specimen—The number of test specimens to be subjected to qualification testing shall depend on the sensor design. If each range is covered by a separate and distinct design, a test specimen for each range may require testing. In instances where a singular design series may cover multiple
ranges and types, only three test specimens may need to be tested provided the electrical and mechanical similarities are approved by the purchaser. In no case, however, should less than three units, one unit each representing low, medium, and high ranges, be tested, regardless of design similarity.

11. Test Data

11.1 Test Data—All test data shall remain on file at the manufacturer’s facility for review by the purchaser upon request. It is recommended that test data be retained in the manufacturer’s files for at least three years, or a period of time acceptable to the purchaser and manufacturer.

12. Inspection

12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

12.1.1 Qualification testing, and
12.1.2 Quality conformance testing.

12.2 Qualification Testing—Qualification test requirements shall be specified where applicable. Qualification test methods should be identified for each design and performance characteristic specified. Test report documentation requirements should also be specified.

12.3 Quality Conformance Testing—Quality conformance testing is accomplished when qualification testing was satisfied by a previous acquisition or product has demonstrated reliability in similar applications. Quality conformance testing is usually less intensive than qualification, often verifying that samples of a production lot meet a few critical performance requirements.

13. Certification

13.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

14. Product Marking

14.1 Purchaser specified product marking shall be listed in the acquisition requirements.

15. Packaging and Package Marking

15.1 Packaging of Product for Delivery—Product should be packaged for shipment in accordance with Practice D 3951.
15.2 Any special preservation, packaging, or package marking requirements for shipment or storage shall be identified in the acquisition requirements.

16.1 Warranty:

16.1.1 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:
16.1.1.1 All materials used to produce a unit, and
16.1.1.2 Manufacturer will warrant his product to be free from defect of workmanship to produce the unit.

17. Keywords

17.1 resistance temperature detector (RTD); thermistor; thermocouple

SUPPLEMENTARY REQUIREMENTS

TEMPERATURE MONITORING EQUIPMENT (NAVAL SHIPBOARD USE)

The following supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard (ASTM F 2362) and this supplement, the requirements of this supplement shall take precedence for equipment acquired by this supplement. This document supercedes MIL-T-15377, Temperature Monitor Equipment, Naval Shipboard, for new ship construction.

S1. Scope

S1.1 This supplement covers temperature monitoring equipment which continuously monitors and selectively indicates, at a central location, a number of temperatures at remote equipment locations on board naval ships.

S1.2 Monitoring Equipment—Monitoring equipment, in conjunction with the temperature sensor assemblies and interconnecting cabling, comprise a temperature measuring and alarm system. In order to warn operating personnel of abnormal temperature conditions, the system shall energize an audible and visual alarm when the temperature at a particular location is below or above a preset limit. Monitoring of temperatures shall be accomplished by measuring the electromotive force (emf) output of thermocouples or by measuring the signal output due to changes in resistance of temperature sensing elements. Temperature monitoring equipment shall actuate external audible alarms specified herein.

S1.3 Selective Temperature Readout Equipment—Selective temperature readout equipment, in conjunction with temperature sensor assemblies and interconnecting cabling, comprise a temperature measuring system. In order to enable operating personnel to measure a number of temperatures at remote points, the system shall enable the operator to manually select the desired point to be measured, convert the selected temperature sensor output to a signal proportional to temperature, and display this signal on a meter calibrated in temperature °C (°F). Readout of temperatures shall be accomplished by measuring the output of thermocouples or by measuring the signal output due to changes in resistance of temperature sensing elements.

S1.4 The U.S. Government preferred system of measurement is the metric SI system. However, since this item was
originally designed using inch-pound units of measurement, in the event of conflict between the metric and inch-pound units, the inch-pound shall take precedence.

S.2. Referenced Documents

S.2.1 Commercial Documents:
- ANSI C96.1 Temperature Measurement Thermocouples
- S.2.2 Government Documents:
- S.2.2.1 Military Standards:
  - MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment
  - MIL-STD-1399 Interface Standard for Shipboard Systems
  - MIL-S-901 Shock Tests, H.I. (High-Impact); Shipboard Machinery, Equipment and Systems, Requirements for
  - MIL-PRF-19207/1 Fuseholders, Extractor Post Type, Blown Fuse Indicating, Type FHL10U
  - MIL-PRF-19207/2 Fuseholders, Extractor Post Type, Blown Fuse Indicating, Type FHL11U

S.3. Terminology

S.3.1 Definitions:
- S.3.1.1 "temperature monitoring equipment"—the necessary equipment required to continuously or selectively sense and indicate various temperatures including audible and visual alarms when specified.

S.4. Classification

S.4.1 Classification—Monitoring and selective temperature readout equipment classification shall be of following format:
Example: ASTM F2362S1-IC/A-1-RTE-40

<table>
<thead>
<tr>
<th>Specification</th>
<th>Type</th>
<th>Alarm</th>
<th>Sensing Techniques</th>
<th>Number of Channels</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2362S1</td>
<td>IC/A</td>
<td>1</td>
<td>RTE</td>
<td>40</td>
</tr>
</tbody>
</table>

S.4.2 Type—The equipment shall be designated by the 3 letter symbols as follows:
- IC/A—Continuous, simultaneous monitoring of remote temperature sensors for alarm and also manual selective temperature readout.
- IC/I—Manual selective temperature readout for measuring temperatures at several remote locations.
- IC/S—Continuous, sequential scanning of remote temperature sensors for indication and alarm.

S.4.3 Alarm—The alarm technique shall be designated by a single number as follows:
1—Alarm on temperature above the set level or (exclusive or) below the set level as operator selected.
2—No alarm provision—temperature readout only.

S.4.4 Temperature Sensing Technique—The temperature sensing technique shall be designated by 3 letter symbols as follows:

---

S.4.4.1 Readout Ranges—Readout ranges shall be provided as specified as follows:
(1) For RTE type sensors, the following ranges and meter scales shall be provided:
(a) 5 to 127°C (-40 to 260°F)
(b) 18 to 205°C (0 to 400°F)
(c) 18 to 427°C (0 to 800°F)
(d) 18 to 538°C (0 to 1000°F)
(2) For type TCE sensors, the following ranges and meter scales shall be provided:
(a) 5 to 127°C (-40 to 260°F)
(b) 18 to 205°C (0 to 400°F)
(c) 18 to 427°C (0 to 800°F)
(d) 205 to 816°C (400 to 1500°F)
(e) 260 to 1093°C (500 to 2000°F)

S.4.5 Number of Channels—The number of channels, corresponding to the number of remote sensors that monitored shall be designated by its numerical value.

S.5. Ordering Information

S.5.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with S.5.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S.5.2 Acquisition Requirements—Acquisition documents should specify the following:
(1) Title, number and date of this specification,
(2) Classification required,
(3) Quantity of items required,
(4) Number of temperature sensors to be monitored,
(5) Setting of alarm channels, if other than 93.3°C (200°F),
(6) Height and weight of equipment assembly,
(7) Number of remote resistance temperature sensors or remote thermocouple temperature sensors monitored by equipment,
(8) Equipment alarm and readout temperature range,
(9) Accuracy or other performance requirements,
(10) Disposition of qualification test samples, and
(11) Unique preservation, packaging and marking requirements.

S.6. Materials and Manufacture

S.6.1 Unless otherwise specified, equipment shall be fabricated from corrosion resistant materials compatible with system piping materials and process medium.

S.7. Physical Properties

S.7.1 Enclosure Assembly:
- S.7.1.1 Temperature Monitor Equipment—Equipment enclosure assembly shall be of sheet metal, splash-proof construction, and shall be suitable for either panel or bulkhead mounting. Splash-proof construction shall be such that water or solid particles directed at the enclosed equipment or its mounting surface shall have no harmful effect on equipment operation.
S7.1.2 Continuous Parallel Monitoring (IC/A)—Enclosure assembly for IC/A monitor equipment shall contain one temperature readout module and the number of alarm modules required to provide the number of alarm channels specified, up to a maximum of 60. Modules shall be readily removable from the enclosure assembly by means of integral plug-in features operable from the front of the enclosure. Access to the interior or back of the enclosure assembly shall not be required to accomplish removal of any module.

S7.1.3 Temperature Readout Module—The temperature module shall be a temperature readout device and associated circuits. Necessary controls shall be located on the front panel of the module.

S7.1.4 Alarm Module (IC/A and IC/I)—Indicator lights and controls shall be located on the front panel of each alarm module to perform the following functions. Multi-position switches may be utilized to combine control functions specified.

1. Power on light (white lens).
2. Alarm light for each temperature monitoring channel (red lens).
3. External alarm cut-out (silence) switch for each temperature monitoring channel.
5. External alarm cut-out (silence) switch for temperature monitoring channels (one per equipment).
6. Alarm circuit reset switch: one per module (if required).
7. Test switch to verify continuity of alarm circuit, alarm light, and temperature sensor (one per module).
8. Read (indicate) light on each temperature monitoring channel to light when it has been selected at the readout module.

S7.1.5 Access (IC/A)—Electrical connection between alarm and readout modules and between modules and the other circuits within the enclosure assembly shall be by means of quick-disconnect connectors. Required auxiliary circuits, such as the power supply, shall be located within the enclosure assembly in such a location as to be readily accessible from the front of the enclosure assembly. Required controls and indicators, associated with the power supply, shall be on the front panel. Fold down or slide drawer chassis construction may be used. Terminals and terminal boards shall be provided for interconnection to ships power, temperature sensors, and external audible alarm. These terminals shall also be located to be accessible from the front of the enclosure assembly. Three 2.44 m (8 ft) long cable assemblies shall be provided and stowed securely inside each equipment enclosure. With these cable assemblies, it shall be possible to remove any one alarm module and the power supply, readout, alarm, and calibration modules to operate the equipment in a normal manner on a work bench away from the installed console. These cable assemblies shall only be required to obtain access for special testing, trouble shooting, and repair.

S7.1.6 Manual Selective Temperature Readout Equipment (IC/I)—Enclosure assembly shall contain the temperature indicating meter, selector switch for selecting the desired temperature sensor to be read, all required, associated functional circuits and parts, and terminals for interconnection to external power and temperature sensors.

S7.1.7 Continuous Scanning Monitoring (IC/S)—Enclosure assembly for IC/S shall contain a readout, a micro processor, input multiplexers, A/D converters, and alarm circuits required to provide the number of channels specified, up to a maximum of 60. Operating controls and the readout shall be accessible from the front panel. A provision shall be included whereby the function of the front panel controls can be disabled to prevent tampering by unauthorized personnel.

S7.1.8 Temperature Monitor Equipment (IC/A)—One identification plate shall be provided for each enclosure assembly. Individual identification plates shall be provided on each module (alarm and indicator unit) showing the location of the associated temperature sensing element, next to each alarm light, and identifying the function of controls and indicators located on the front of each module. As an alternate, identification plates showing location of temperature sensor elements may be provided on the overall equipment frame adjacent to each module location. Plates shall also provide for indicating the proper scale to use on the readout for each channel if a dial type meter is used. Adjustment, calibration, setting, and standardization controls located within the enclosure assembly, shall also be identified by means of identification plates. Temperature sensor connection terminals shall be marked to correspond with the position identification for monitor point.

S7.1.9 Selective Temperature Readout Equipment (IC/I)—The position of all selector switches shall be marked to identify the temperature sensor selected to be measured. Adjustment, calibration, and sensor connection terminals located within the enclosure assembly shall be identified and marked.

S7.1.10 Continuous Scanning Monitoring (IC/S)—The equipment display shall identify the location of the temperature element when an alarm condition occurs.

S7.2 System Requirements:

S7.2.1 Temperature Monitor Equipment (IC/A)—IC/A temperature monitor equipment shall provide for continuous paralleled monitoring of up to 60 temperature sensors. Equipment shall be modular, with individual modules having plug-in features as specified in S7.1.2. There shall be at least 3 types of modules:

1. Monitor and alarm,
2. Readout, and
3. Power supply module.

Each monitor and alarm module shall monitor 4 temperature sensors. Equipment shall be capable of operating, as specified herein, with each of the 60 temperature alarm set points adjusted for a different temperature setting. Any alarm may be activated regardless of the state of any other alarm. For purposes of standardization, the factory setting shall be approximately 93.3°C (200°F) for points, unless otherwise specified in the acquisition requirements.

S7.2.2 Visual Alarm—Each monitor point shall be uniquely associated with a specific remote temperature sensor and shall have its own individual indicating light. When the temperature at the point being monitored reaches a predetermined temperature setting (alarm point), the indicator light shall be energized and remain energized until manually reset.
S7.2.3 *Audible Alarm*—One relay or electronic switch having 5 A minimum rating DPDT operation shall be provided for supplying 115 V alternating current (ac) power for actuating an external audible alarm simultaneously with activating the visual alarm. The alarm relay switch shall be wired to the panel terminal boards in the cable entrance stuffing box. The audible alarm shall be activated when any one or more of the temperatures being monitored reaches the predetermined (alarm) setting. Each channel shall provide a manual switch for cutting out the audible alarm for its own monitoring point. This cut-out shall not prevent any of the other channels from sounding the audible alarm should the temperature at any other monitored point reach the predetermined (alarm) setting. A single, master cut-out switch with associated indicator light shall be provided, which will disable the sounding of the external audible alarm for the entire system.

S7.2.4 *Independent Action*—The monitoring and alarm action of individual points shall be independent of each other. Action of indicating an alarm condition at one or more monitor points shall not prevent the system (equipment) from indicating an alarm condition at other monitor points.

S7.2.5 *Temperature Readout*—The temperature readout device and channel selector switch shall be provided in a readout module. The selector switch shall be depressed to turn so that momentary contact is not made with intermediate channels. The continuous, automatic monitor and alarm capability of the system shall not be affected by the selection of a temperature sensor for reading. When a channel temperature reading is being taken, the alarm feature of all points including the one being measured shall be maintained. The operation of the readout module shall not depend on balancing motors, slidewires, potentiometers, or similar devices. The use of potentiometers shall be limited to test, adjustment, and calibration purposes only.

S7.2.6 *Test Feature*—A test switch shall be provided for each monitor and alarm module for testing alarm lights and continuity of each temperature sensor and alarm circuits of that module. When the switch is operated to the “test” position, the channel alarm light shall indicate an alarm condition. Failure of the channel alarm light on the module to light shall indicate an open circuit in the lamp, temperature sensor, or in the associated alarm circuit. This test operation shall not change the normal state of the alarm relays or external relays.

S7.2.7 *Fail Safe Design*—The IC/A temperature monitor equipment shall have an inherent “fail safe” feature. An open circuit in the external temperature sensor or its connecting cabling shall result in an alarm condition.

S7.2.8 *Calibration and Setting of Alarm Point*—Design of the IC/A temperature monitor equipment shall be such as to facilitate calibration and adjustment of the individual alarm set points. Self calibration capability shall be an inherent design feature. Test jacks shall be provided to facilitate direct connection to external instrumentation for test, calibration, and trouble shooting. Calibration, alarm set point adjustment and access to the test jacks shall not require disassembly or changes to the electrical wiring connections.

S7.2.9 *Cold Junction Compensation*—Cold junction compensation for equipment for thermocouple sensing shall be self-contained, automatic, and shall be referenced to 0°C (32°F).

S7.2.10 *Lead Length Compensation*—Equipment for resistance temperature sensing shall provide an input terminal for 3 wire sensor configuration. A means shall be provided to compensate for the resistance of interconnecting wiring between sensor and monitor equipment. This compensating provision and associated sensor input terminal configuration shall be arranged that it can be easily by-passed (removable jumper, alternate terminals, or similar means) for use with 2 wire resistance temperature elements. Equipment for thermocouple sensing shall provide for thermocouple lead length compensation. Accuracy, calibration, and response time shall be independent of thermocouple extension lead length.

S7.2.11 *Size and Weight*—Individual modules (alarm or readout) shall not exceed 15.24 cm (6 in.) in height, 7.62 cm (3 in.) in width, and 30.48 cm (12 in.) in depth. Total weight per module shall not exceed 5.44 kg (12 lb). The equipment assembly, containing the required number of alarm modules, the readout module, and power supply module shall not exceed 50.8 cm (20 in.) in width, and 35.6 cm (14 in.) in depth. The height and weight, determined by the number of temperatures the equipment is designed to monitor, shall be as specified in the acquisition requirements. The equipment assembly, containing the required number of alarm modules to monitor 60 temperatures, shall not exceed 129.6 cm (51 in.) in height. Total weight shall not exceed 90.7 kg (200 lb). For a 40 point monitor system, the equipment assembly shall not exceed 91.44 cm (36 in.) in height, and weight shall not exceed 68 kg (150 lb).

S7.2.12 *Selective Temperature Readout Equipment (IC/I)*—Equipment shall provide for the manual selection of any one of several remotely located temperature sensors and converting the signal output of the selected sensor to the signal required for display on a read-out device, calibrated in °C (°F). The operation of the readout equipment shall not depend on balancing motors, slide-wires, potentiometers, or similar devices. Use of potentiometers shall be limited to test, adjustment, and calibration purposes only. The equipment shall facilitate calibration without disassembly or changes to the electrical wiring connections. Test jacks shall be provided to permit direct connection to test and calibration instruments. An inherent “fail safe” feature shall be incorporated which will result in an off-scale (high or low) reading to signal a failure in the manual selector, associated readout circuits, or an open or short in the external temperature sensor.

S7.2.12.1 *Size and Weight*—Selective temperature readout equipment assembly shall not exceed 30.48 cm (12 in.) in width, 30.48 cm (12 in.) in height, and 35.6 cm (14 in.) in depth. The total weight shall not exceed 18.14 kg (40 lb).

S7.2.13 *Continuous Scanning Monitoring, Indicating, and Alarm Equipment (IC/S)*—IC/S temperature monitor equipment shall provide for continuous scanning via micro processor of up to 60 temperature sensors. Equipment shall be modular, with individual modules having plug-in features. The equipment shall scan at a rate which will allow all channels to be
scanned in 5 s or less. Alarm set points and temperature input characteristics shall be able to be re-programmed from the front panel. The equipment shall be capable of annunciating alarms regardless of number (up to 60) and regardless of previous alarm history.

S7.2.14 Number of Readout Points (IC/A, IC/I, and IC/S)—The number of remote resistance temperature sensors or remote thermocouple temperature sensors monitored by the equipment shall be specified in the acquisition requirements.

S7.3 Parts Requirements—Electrical parts, mechanical parts, processes, and material shall be selected and applied to meet the requirements herein.

S7.3.1 Batteries—Batteries shall not be used.

S7.3.2 Electrical Indicating Meters—Electrical indicating meters shall be high-impact shock resistant, watertight, or hermetically sealed types, in accordance with one of the following:

1. 11.43 cm (4-1/2 in.) 250º nominal scale length.
2. Panel mounted, edgewise type.

S7.3.3 Digital Readout—Digital meters utilized in lieu of an electrical indicating meter (analog type readout) shall have a minimum of 4 digits. The meters shall be high-impact shock resistant, and watertight, or hermetically sealed.

S7.3.4 Fuses—Fuses shall be selected so that the overload blowing characteristics and short circuit interrupting capacity matches the overload protection requirements of the equipment and wiring being protected and the short circuit capacity of the supply circuit.

S7.3.5 Fuse Mounting—Fuses shall be mounted in panel mounted, indicating type fuse-holders. Fuse-holders FH10 in accordance with MIL-PRF-19207/1 or FH11 in accordance with MIL-PRF-19207/2 are preferred types.

S7.3.6 Terminal Boards and Mounting—Terminal boards shall be stud type and shall be secured only by bolts (machine screws) and shall be capable of ready removal and replacement. They shall be accessible from the front of the enclosure with the front cover plate removed or access door open.

S7.3.7 Switches—Switches shall be selected so that rated currents and voltages (make, break, carry) are not exceeded in the intended application, as well as for their ability to withstand the shipboard environments. Rotary switches are preferred for power circuit interruption. Readout channel selector switch shall be a "push to turn" type so that momentary contact is not made with intermediate channels while turning the switch.

S8. Performance Requirements

S8.1 Calibration and Accuracy—Temperature monitoring equipment, selective temperature readout equipment, and continuous scanning temperature monitoring equipment shall comply with the calibration and accuracy requirements specified below. Equipment performance requirements specified herein are specified on the basis of simulating the signal output of the appropriate temperature sensors and applying this signal to the input terminals (temperature sensor terminal points) of the equipment.

S8.1.1 Accuracy of Alarm Set Point—Temperature monitoring equipment (IC/A, IC/I, and IC/S) shall permit the setting of the alarm point at any value over the designated temperature span. The error band of the alarm level setting shall be one-half the error band of the temperature readout on any full scale range.

S8.1.2 Accuracy of Readout—The readout error of the equipment shall not exceed ±2 % of the readout range for any readout range setting. The temperature indicated on the readout device shall be within ±2 % of the temperature equivalent to the simulated temperature sensor output in ohms or millivolts, as applicable.

S8.2 Ambient Temperature Error—The change in temperature reading (temperature error) of the equipment due to any changing ambient temperature from 4.5 to 65ºC (40 to 149ºF) shall not exceed 0.18 (0.1) % of full scale per °C (°F) change in ambient temperature.

S8.3 Response Time:

S8.3.1 Alarm Circuits (IC/A and IC/I)—The alarm shall be actuated within 0.1 s when a step signal change of 1.5 % of full scale is applied when the monitoring systems are reading 1.4 % of full scale below the alarm setting for any alarm setting from 5 to 100 % of full scale.

S8.3.2 Alarm Circuits (IC/S)—The alarm shall be actuated on the first scan cycle after the alarm condition appears at the input of the equipment. Alarms shall be programmable to actuate either above a set condition or below a set condition.

S8.3.3 Temperature Readout—Equipment shall display the steady state temperature reading ±2.0 % in less than 3 s when a step signal equivalent to 80 % (from 10 to 90 %) of full temperature span is applied to the temperature sensor input terminals of the temperature monitoring equipment console.

S8.3.4 Compensation for RTE—Equipment shall provide for 3 wire temperature sensor inputs. Means shall be provided to compensate for the resistance of interconnecting wiring between temperature sensor and the indicator equipment. Compensating provision and associated sensor input terminal configuration shall be so arranged that it can be easily bypassed (removable jumper, alternate terminals, or similar means) for use with 2 wire uncompensated resistance temperature sensors.

S8.3.5 Compensation for TCE—Cold junction compensation shall be self-contained, automatic, and shall be reference to 0ºC (32ºF).

S8.4 Operation:

S8.4.1 Temperature Monitor Equipment—When the equipment is operated under nominal conditions simulating shipboard service (see S11.3), equipment operation shall comply with the following:

1. Individual visual alarm indicators light when associated test switch is operated (applicable to IC/A and IC/S equipment).

2. Test, reset, and audible alarm cut out switches operate as required.

3. Indicator reads required temperature when test and select (or indicate as applicable) switches are operated. Readout accuracy shall be in accordance with S8.1.2.

4. Alarm indication activated with temperature sensor terminals open or short circuited, except instruments for thermocouple sensors need not detect a short.

S8.4.2 Selective Temperature Readout Equipment—When the equipment is operated under nominal conditions simulating
shipboard service (see S11.3), equipment operation shall comply with the following:

(1) Accuracy of readout (see S8.1.2).

(2) Selector switch operates in accordance with S8.4.1.(3).

(3) Indicator scale is driven to either extreme low or high with temperature sensor terminals open or short circuited.

S8.4.3 Power Supply Requirements—Equipment shall operate normally from type I power as defined in MIL-STD-1399, Section 300. Nominal power input voltage and frequency shall be 115 V, 60 Hertz (Hz), single phase. Power line transients and spikes with magnitudes, duration, repetition rates, and decay characteristics as specified in MIL-STD-1399, Section 300 shall not cause equipment damage or affect equipment operation. The maximum difference in indicator reading and alarm setting level at any voltage and frequency condition and nominal (115 V, 60 Hz) with the same input, shall not exceed 1/2 of 1 % of full scale on all ranges.

S8.5 Warm-up Time—Transducer output shall attain a value within ±1 % of the steady-state output with no overshoot in excess of 1 %. Output shall reach this band in 30 min or less and shall remain in this band (see S11.4).

S8.6 Inclination—Maximum deviation of indication resulting from inclination shall not exceed 1.0 % (see S11.5).

S8.7 Enclosure—There shall be no evidence of water leakage into the equipment enclosure (see S11.6).

S8.8 Insulation Resistance—The insulation resistance shall be not less than 10 megohms between power input lines and ground (hull).

S8.9 Shock—The temperature monitoring equipment shall show no evidence of mechanical or electrical damage or loosening of parts, when exposed to shock in accordance with MIL-S-901.

S8.9.1 Temperature Monitor and Readout Equipment (IC/A, IC/I, and IC/S)—Operating controls shall not change status during shock. There shall be no transfer of switch or relay contacts or change in selector switch position during shock. After shock, without any adjustments, the equipment shall meet the following requirements:

(1) Alarm set point accuracy as specified in S8.1.1 (as applicable).

(2) Indicator accuracy in accordance with S8.1.2.

(3) Operation shall be in accordance with S8.4.

S8.10 Vibration—Temperature indicating and monitoring equipment shall operate in accordance with the requirements herein when exposed to type I environmental vibration of MIL-STD-167-1. Equipment range and accuracy requirements shall be demonstrated during and after completion of vibration. Equipment shall show no evidence of mechanical or electrical damage or loosening of parts. Operating controls and relays shall not change status during vibration. There shall be no momentary or permanent transfer of switch or relay contacts or change in selector switch position during vibration.

S8.11 Temperature—Equipment shall operate in accordance with S8.4 when exposed to ambient temperature conditions from 0 to 65°C (32 to 149°F). The equipment shall not be damaged in a non-operating condition when exposed to ambient temperatures of -40 to 70°C (-40 to 158°F).

S9. Workmanship, Finish, and Appearance

S9.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burr-through. There shall be no warpage or dimensional change due to heat from welding operation. There shall be no damage to adjacent parts resulting from welding.

S10. Number of Tests and Retests

S10.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S11. Test Methods

S11.1 Calibration and Accuracy—Monitor and readout equipment calibration and accuracy measurements shall be accomplished by simulating temperature sensor signal output over the designated temperature span. Simulated signal for equipment using the resistance sensing technique shall be resistance values as specified in Appendix B and shall be simulated by a resistance decade (or similar device) having an accuracy of ±0.055 Ω. The simulated signal for equipment using the thermocouple sensing technique shall be millivolts (mV) as specified in ANSI C96.1 and shall be simulated by a stable direct current (dc) voltage source having an accuracy of ±0.025 mV.

S11.1.1 Accuracy of Alarm Set Point—Alarm set points shall be calibrated and adjusted in accordance with the instructions contained in the technical manual furnished with the equipment. The accuracy of the alarm set point shall be checked at 5 different temperatures approximately equally spaced over the temperature span for each alarm channel. A signal simulating the temperature sensor output shall then be applied to the equipment input terminals. The accuracy of the alarm set point shall be checked with both increasing and decreasing signals. The signal required to actuate the alarm shall be within the limits specified in S8.1.1.

S11.1.2 Accuracy of Readout—The accuracy of the readout portion of equipment types shall be determined at approximately equally spaced intervals over each readout temperature span. The reading, at each simulated temperature input, shall be as specified in S8.1.2.

S11.1.3 Lead Resistance Compensation—For equipment which operates with RTE sensors, one of the measurements specified in S11.1.1 and S11.1.2 shall be repeated by inserting a resistance in series with each lead of the resistor simulating the RTE to simulate lead resistance. The resistance in each lead shall be any value between 20 and 30 Ω, but the resistance for each lead shall be equal to each other within 0.1 Ω.

S11.2 Response Time:

S11.2.1 Alarm Circuits—Compliance with S8.3.1 shall be demonstrated by testing at 10, 20, 50, 90, and 100 % of the full alarm setting range.

S11.2.2 Temperature Readout—A step input signal, equal to 80 % of the temperature span (from 10 to 90 % of the span) for
shall be subjected to the following examinations and tests:

S11.3 Operation (Monitor and Readout Equipment)—Equipment shall be energized with nominal voltage and frequency (115 V, 60 Hz) and allowed to stabilize for at least 30 min. Input signals, simulating temperature sensor outputs equivalent to approximately mid-range of the temperature span, shall be connected to all equipment input terminals. Equipment controls shall then be actuated in turn to verify compliance with S8.4.1 and S8.4.2. Indicator readings shall be noted and recorded. The supply voltage and frequency shall then be adjusted to the lower limit of permissible variation (see S8.4). Equipment shall be stabilized at this input power for at least 15 min and indicator reading shall be noted and recorded. Supply voltage and frequency shall then be adjusted to the higher limit, stabilized for at least 15 min, and the indicator reading noted and recorded. Temperature sensor inputs during these tests shall remain constant. The change in indicator reading, due to variations in input power shall be within the limits specified in S8.4.

S11.4 Warm-up Time—Test shall be conducted to determine the elapsed time between the application or line power to the equipment and the point at which the indication reaches the conditions specified in S8.5.

S11.4.1 The transducer shall be placed in an ambient temperature of 25 ± 2°C (77 ± 3.6°F) for not less than 2 h de-energized. Recording equipment and other auxiliary equipment shall be energized to assure complete warm-up. A simulated signal equal to 80 % of span shall be applied and maintained constant during this test. Performance shall conform to S8.5.

S11.5 Inclination—The equipment shall be inclined for a period of at least 1 min in each of the following positions:

1. 45° forward
2. 45° backward
3. 45° to the left
4. 45° to the right

In each position a reference measurement (see S11.1) shall be made. Performance shall conform to S8.6.

S11.6 Enclosure—The enclosure shall be subjected to a solid stream of water from a 2.54 cm (1 in.) nozzle at 246 L (65 gal) per minute at a distance from the equipment of approximately 3.05 m (10 ft). The water stream shall be directed at all surfaces of the enclosed equipment and its mounting surface for a minimum of 5 min. Performance shall conform to S8.7.

S11.7 Insulation Resistance—Insulation resistance shall be determined with a test potential of 50 Vdc applied for a minimum of 60 s.

S11.8 Shock—Equipment and sensor assemblies shall be tested in accordance with the high-impact shock test specified in MIL-S-901 for grade A, class I, type C equipment.

S11.8.1 Monitor and Readout Equipment—The equipment shall be energized during the test with nominal voltage and frequency (115 V, 60 Hz) and sensor input signals shall be 80 % of span. During the test, all operating controls shall be observed for change in status. After the shock test, equipment shall be subjected to the following examinations and tests:

1. Alarm set point accuracy (see S11.1.1),
2. Readout accuracy (see S11.1.2),
3. Operation at nominal voltage and frequency (see S11.3),
4. Examination for evidence of mechanical damage or loosening of parts.

S11.9 Vibration—Equipment and sensor assemblies shall be tested in accordance with type I vibration of MIL-STD-167-1. Energization, input signals, observations during test and examinations after vibration shall be as specified in S11.8 for the shock test. IC/A system shall have the alarm point set within 4 % of full scale of the incoming temperature level. The temperature level shall be at 90 % of full scale. If an alarm occurs during vibration, any vibration test is a failure and corrective action is required. Frequency variation tests of MIL-STD-167-1 are required with the same settings. It shall be demonstrated that vibration from 1 to 50 Hz in accordance with MIL-STD-167-1 shall not cause alarm.

S11.10 Temperature:

S11.10.1 Operating—The equipment shall be subjected to the following temperature cycles:

<table>
<thead>
<tr>
<th>Period (h)</th>
<th>Temperature (°C)</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>0°C (32°F)</td>

</tr>
<tr>
<td>6</td>
<td>25°C (77°F)</td>
<td>Stable room or chamber</td>
</tr>
</tbody>
</table>

Cycle periods shall be measured from the time the temperature is stabilized. All tests within a 6-h period shall be continuous. Performance during and after the tests shall conform to S8.11.

S11.10.2 Non-operating—The equipment shall be held at each of the two temperature extremes for a period of 24 h. Performance after the test shall conform to S8.11.

S12. Inspection

S12.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

(a) Qualification testing,

(b) Quality conformance testing.

S12.2 Qualification—Qualification tests shall be conducted at a laboratory satisfactory to the purchaser. Qualification tests shall consist of the general examination and the tests specified in Table S1 and shall be conducted on equipment produced with techniques and procedures normally used in production.

S12.2.1 Qualification Sample—Monitor and Readout Equipment—One sample of each type and temperature sensing

technique with the maximum number of channels for which qualification is sought shall be submitted for examination and test.

S12.2.1.1 Extent of Qualification—Qualification of an equipment type will also be extended to equipment of the same design, type, and sensing technique, with lesser number of channels.

S12.2.2 Test Routine—Equipment submitted for qualification testing shall be subjected to the tests shown in Table S1 in the order listed. Failure of an equipment to comply with any of the requirements listed shall cause refusal to grant qualification.

S12.2.3 Disposition of Qualification Samples—Samples subjected to qualification testing shall be considered consumed and non-deliverable as part of the contract. Final disposition of qualification samples shall be specified in the acquisition requirements.

S12.3 Quality Conformance Testing—The sample equipment or sensor assemblies selected shall be subjected to the examinations and tests listed in Table S3. Examinations and tests shall be performed in the order listed.

S12.3.1 Lot—Equipment of the same type presented for quality conformance inspection at one time shall be considered a “lot.” The lot may include the entire contract quantity, or it may be the production of any convenient time period. Each equipment shall be subjected to general examination and accuracy test.

S12.3.2 Sampling—A sample of equipment shall be selected from each lot in accordance with Table S2 and subjected to the examinations and tests specified in Table S3. If the number of nonconforming equipment in any sample exceeds the acceptance number for that sample, the lot represented by the sample shall be rejected.

S12.4 Test Conditions—Except for those tests where the following factors are the variables, tests shall be conducted with the equipment operating under the following conditions:

(1) The ambient temperature shall be 25 ± 3°C (77 ± 5.4°F), and the relative humidity shall be between 25 and 50 %.

(2) The supply voltage shall be 115 V nominal.

(3) The supply frequency shall be 60 Hz nominal.

S12.5 General Examination—The temperature monitoring equipment shall be given a thorough examination to determine that it conforms to this specification and the approved drawings with respect to material, finish, construction, assembly, dimensions, workmanship, marking, identification, and information plates. This examination shall be limited to those examinations that may be performed without disassembling the unit in such a manner that its performance, durability and appearance would be affected. This examination shall include a mechanical check of all operating controls and adjustments, as applicable.

S13. Certification

S13.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data remain on file for three years at the manufacturer’s facility for review by purchaser upon request.

S14. Product Marking

S14.1 Product marking requirements shall be specified in the acquisition requirements.

S15. Packaging and Package Marking

S15.1 Packaging and package marking shall be in accordance with Section 15.

S16.1 Warranty—Special warranty requirements shall be specified in the acquisition requirements. Otherwise, the standard commercial warranty applies.
S17. Scope

S17.1 This specification covers the requirements for signal conditioners and electrical power supplies used in conjunction with thermocouples and resistance temperature element assemblies for naval ships. It does not include the design of the sensing elements and wells or the requirements for the readout or display.

S17.2 This specification defines equipment intended to provide control input and monitoring of temperatures for shipboard engineering plants.

S17.3 The U.S. Government preferred system of measurement is the metric SI system. However, since this item was originally designed using inch-pound units of measurement, in the event of conflict between the metric and inch-pound units, the inch-pound units shall take precedence.

S18. Referenced Documents

S18.1 Commercial Documents:

S18.2 Government Documents:
MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment (Type I—Environmental and Type II—Internally Excited)

S18.2.1 Military Standard:
MIL-STD-167-1 Mechanical Vibrations of Shipboard Equipment (Type I—Environmental and Type II—Internally Excited)

S18.2.2 Military Specifications:

S19. Terminology

S19.1 Definitions:
S19.1.1 thermocouple, shall be as defined by S34.
S19.1.2 resistance, shall be as defined by Section S34.
S19.1.3 deadband, the range through which the measurand can be verified without a change in output.
S19.1.4 static error band, the maximum deviation of sensor output from the straight line drawn through the coordinates of the lower span limit at specified output, and the upper span limit at specified output expressed in percent of span.

---

S20. Classification

Temperature monitoring equipment shall consist of a series of designs which shall be assigned and listed in the format below.

Example: ASTM F2362S17-TRE-4H-YES

<table>
<thead>
<tr>
<th>Specification Type</th>
<th>Input Range</th>
<th>Alarm and Repeater Circuits</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2362S17 TRE</td>
<td>4H</td>
<td>YES</td>
</tr>
</tbody>
</table>

S20.1 Type—Temperature measurement equipment shall be designated by the three letter symbols as follows:

TRE—Temperature Resistance Equipment, platinum
TTE—Temperature Thermocouple Equipment, type K

S20.2 Input Range—The temperature range in degrees Fahrenheit (°F) shall be designated by its numerical value (see S20.2.1.1 and S20.2.2.1).

S20.2.1 Temperature Resistance (Type TRE) Input:
S20.2.1.1 Ranges—Equipment temperature range shall be as specified in the acquisition requirements. Ranges shall be in accordance with the following:

<table>
<thead>
<tr>
<th>Range</th>
<th>Designation</th>
</tr>
</thead>
<tbody>
<tr>
<td>-40 to 127°C (-40° to 260°F)</td>
<td>26</td>

<td>4H</td>
</tr>
<tr>
<td>-18 to 538°C (0° to 1000°F)</td>
<td>1K</td>
</tr>
</tbody>
</table>

S20.2.1.2 Excitation Current—The maximum current through the resistance temperature element shall be 6 ma, dc.

S20.2.1.3 Lead Wire Resistance Compensation—The equipment input for resistance sensing technique shall be of three-wire configuration. A means shall be provided to compensate for the factors which introduce error such as self heating and the resistance of interconnecting wiring between the sensor and signal conditioner.

S20.2.2 Temperature Thermocouple (Type TCE) Input:
S20.2.2.1 Ranges—Equipment temperature range shall be as specified in the acquisition requirements. Ranges shall be in accordance with the following:

<table>
<thead>
<tr>
<th>Range</th>
<th>Designation</th>
</tr>
</thead>
<tbody>
<tr>
<td>-40 to 93°C (-40° to 200°F)</td>
<td>2H</td>

<td>15H</td>
</tr>
</tbody>
</table>

S20.2.2.2 Cold Junction Compensation—Cold junction compensation for thermocouple sensing technique shall be automatic and shall be referenced to 0°C (32°F).

S21. Ordering Information

S21.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with S21.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S21.2 Acquisition Requirements—Acquisition documents should specify the following:
S22. Materials and Manufacture

S22.1 Except where specifications are referenced, materials shall be in accordance with commercial specifications having material compositions suitable for service in the shipboard marine environment.

S23. Physical Properties

S23.1 Description—The equipment specified herein in conjunction with the thermocouples or resistance temperature elements specified in Appendix B comprise a temperature instrument. The temperature measurement equipment generally consists of the following units:

(1) Signal Conditioner—The signal conditioner shall convert the sensing element output to a continuous linear analog signal directly proportional to temperature.

(2) Power Supply—The power supply shall provide excitation energy to the signal conditioner and sensor.

(3) Test Device—A test device shall be furnished to provide a calibrated test signal used for calibrating the equipment.

The various assemblies of temperature measurement equipment shall be built integrally together and housed in the same enclosure.

S23.2 Output—The electrical signal output of the equipment shall be dc, directly proportional to temperature input. The output shall be 4 to 20 ma, dc into an external resistance of 550 ± 10 % σ.

S23.3 Calibration Means—A means shall be provided to monitor equipment output corresponding to temperature input to permit in place calibration by one man. Each temperature instrument shall contain a test switch and a temperature detector simulator capable of supplying a test signal into the instrument circuitry. This test device shall have a calibrated dial and shall replace the detector when the instrument is in the test mode. The signal from this simulator shall be of sufficient accuracy to determine static error band (see S24.2) and repeatability (see S24.3). Test jacks shall be provided to monitor the equipment output and detector output. Placing the instrument in the test mode shall allow remote monitoring of the detector. Calibration shall be effected without the necessity of electrical disconnection.

S23.4 Equipment Range—Equipment range shall be determined by means of an interchangeable assembly or internal adjustments.

S23.5 Adjustments—Tamper-proof adjustments for zero and span shall be provided for calibration purposes. The number of adjustments shall be kept to a minimum, consistent with the operation and maintenance of the equipment and the elimination for the selective matching of parts.

S23.6 Fail Safe Output—If the input of the signal conditioner is open circuited, the output shall drive upscale or downscale, the choice of which shall be made by means of a link.

S23.7 Isolation—Input and output circuits shall be isolated from each other and from ground.

S23.8 Enclosure—Temperature measurement equipment shall be mounted in a junction box. The junction box may be in accordance with MIL-J-24142 and MIL-J-24142/3. At a minimum, the size, mounting, and cable interface shall be per MIL-J-24142 and MIL-J-24142/3. All adjustments and test points shall be accessible when the cover is removed. Temperature measurement equipment shall be designed for bulkhead or bracket mounting.

S23.9 Weight—The weight of the complete equipment shall be kept to a minimum commensurate with good engineering design.

S23.10 Power Supply Requirements—The equipment shall be designed to operate with line variations as specified in S27.9 and S27.12. Nominal steady state power supply requirements shall be 115 ± 10 % V at 60 ± 5 % hertz (Hz), single phase, unless otherwise specified in the acquisition requirements.

S23.11 Cable Entrance and Connection—Cable entrance shall be by means of stuffing tubes located on the bottom surface of the enclosure.

S23.12 Operation—The operation of the equipment shall not depend on balancing motor, slide wires, or similar devices. The system shall be completely static. The use of potentiometers are for test and adjustment purposes only.

S23.13 Resistors—Composition type fixed or variable resistors shall not be used.

S23.14 Batteries—Batteries shall not be used.

S23.15 Modular Assemblies—Modular units or assemblies shall be fastened in such a manner to allow for quick and easy removal for maintenance accessibility or replacement.

S23.16 Terminal Boards—The interface with shipboard wiring shall be by means of terminal boards. These terminals shall be accessible with the coverplate removed.

S24. Performance Requirements

Performance tolerances are expressed in percent of equipment span unless stated otherwise.

S24.1 Service Life—Equipment shall be designed for a minimum service life of 40,000 h in a shipboard marine environment.

S24.2 Static Error Band—The static error band shall not exceed plus or minus 1 % (see S27.2).

S24.3 Repeatability—Repeatability of the output shall not exceed 0.3 % (see S27.2).

S24.4 Threshold and Deadband—The maximum least detectable increment plus deadband shall not exceed 0.2 % (see S27.4).

S24.5 Ripple—Equipment output ripple shall not exceed 0.15 % of full scale output (see S27.5).

S24.6 Warm-up Time—The equipment output shall attain a value within plus or minus 1 % of the steady state output with no overshoot in excess of 1 %. Output shall reach this band in 30 min or less and shall remain in this band (see S27.6).
S24.7 Inclination—Maximum deviation of equipment output resulting from inclination shall not exceed 1.0 % (see S27.7).

S24.8 Input Resistance—The equipment output shall remain within the static error band (see S24.2 and S27.8).

S24.9 Supply Voltage and Frequency (Steady State)—Maximum difference between outputs at any voltage and frequency condition and the normal (115 V, 60 Hz) at the same input shall not exceed 1.0 % (see S27.9).

S24.10 Response Time—The 95 % response time shall be 0.5 s or less (see S27.10).

S24.11 Supply Voltage and Frequency (Transients):
- S24.11.1 Voltage—When the equipment is exposed to the limits of specified voltage transient, the equipment output shall remain within ±1 % of the steady state output (see S27.11).
- S24.11.2 Frequency—When the equipment is exposed to the limits of specified frequency transient, the equipment output shall remain within ±1 % of the steady state output (see S27.11).

S24.12 Temperature—When the equipment is exposed to the ambient temperature extremes, performance shall be within the static error band specified in S24.2 (see S27.12).

S24.13 Insulation Resistance—The insulation resistance of the equipment between circuits and between circuits and ground shall be not less than 10 megohms (see S27.13).

S24.14 Vibration—When the equipment is exposed to vibration in accordance with MIL-STD-167-1, monitored output test shall show no variation from steady state output in excess of 2.0 %. There shall be no visible evidence of damage to the equipment as a result of the vibration (see S27.14).

S24.15 Shock—After exposure to shock in accordance with MIL-S-901 but prior to any adjustment, the equipment output shall show no deviation greater than 3 %. A post shock calibration, using adjustments provided, shall conform to performance requirements of S24.2. There shall be no visual evidence of damage to the equipment as a result of the shock (see S27.15).

S25. Workmanship, Finish, and Appearance

S25.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change due to heat from welding operation. There shall be no damage to adjacent parts resulting from welding.

S26. Number of Tests and Retests

S26.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S27. Test Methods

S27.1 General Examination and Operation—The unpow-ered temperature monitoring equipment shall be given a thorough examination to determine conformance to the requirements of this specification with respect to material, color, finish, workmanship, safety, construction, assembly, dimensions, weight, and marking of identification plates. Examination shall be limited to the examinations that may be performed without disassembling the unit in such a manner that its performance, durability, or appearance would be affected.

S27.2 Static Error Band and Repeatability—Prior to the start of this test, the test sample and associated test equipment shall be energized for a period of 2 h. The test sample shall first be cycled over its full temperature range by slowly increasing and decreasing the input for six continuous cycles. The calibration measurements shall be made at a minimum of 5 equally spaced intervals over the entire range (both upscale and downscale). Precaution shall be taken to avoid overshoot. This calibration procedure shall be applied three successive times to determine repeatability. Static error band of all calibrations shall meet the requirements of S24.2. Repeatability shall meet the requirements of S24.3.

S27.3 Reference Measurement—A one trial calibration with at least five equally spaced intervals over the entire input range both upscale and downscale shall be conducted when specified in the individual test.

S27.4 Determination of Threshold and Deadband—Threshold and deadband shall be determined with 80 ± 5 % of the temperature span applied to the test sample. The temperature interval beyond this point required to produce a detectable change in output and the temperature interval in the opposite direction to return the output to the original value shall be determined in each direction. Threshold is the first temperature interval. The second temperature interval is the sum of the threshold and deadband. Performance shall conform to the requirements of S24.4.

S27.5 Ripple—equipment Output—Ripple shall be determined at an input of 80 ± 5 % of the temperature span. Performance shall conform to the requirements of S24.5.

S27.6 Warm-up Time—This test shall be conducted to determine the elapsed time between the application of line power to the test sample and the point at which the equipment output reaches the conditions specified in S24.6. The test sample shall be placed in an ambient temperature of 25 ± 2°C (77 ± 3.6°F) for not less than 2 h de-energized. Recording equipment and other auxiliary equipment shall be energized to assure complete warm-up. An input of 80 ± 5 % of the span is to be applied to the test sample and maintained constant during this test. Performance shall conform to S24.6.

S27.7 Inclination—The equipment shall be inclined for a period of at least 1 min in each of the following positions:
1. 45 degrees forward
2. 45 degrees backward
3. 45 degrees to the left
4. 45 degrees to the right

In each position a reference measurement (see S27.3) shall be made. Performance shall conform to S24.7.

S27.8 Input Resistance—For thermocouple sensing technique, a noninductive resistance of 150 ± 1 % Ω shall be placed in each lead to the input terminals to total a circuit resistance of approximately 300 Ω. A reference measurement (see S27.3) shall be made. Performance shall conform to S24.8.
S27.9 **Supply Voltage and Frequency (Steady State)**—The equipment shall be operated at the various combinations of normal, maximum and minimum steady state voltages and frequencies outlined in S24.9. The equipment shall be operated at least 15 min in each combination during which time a reference measurement (see S27.3) shall be taken. Performance shall conform to S24.9.

S27.10 **Response Time**—A step input equal to 10 to 90 % of full scale equipment temperature span shall be applied to the test sample. Performance shall conform to S24.10.

S27.11 **Supply Voltage and Frequency (Transient)**—The tests specified in S27.11.1 through S27.11.2 shall be conducted with a temperature input signal equal to 80 ± 5 % of the input span. Performance shall conform to S24.11.

S27.11.1 **Transient Voltage**—With the equipment operating on the upper limit of steady state voltage, a transient voltage of plus 20 % of nominal voltage recovering to the steady state band in 2 s shall be superimposed. With the equipment operating on the lower limit of steady state voltage, transient voltage of minus 20 % of nominal voltage recovering to the steady state band in 2 s shall be superimposed.

S27.11.2 **Transient Frequency**—With the equipment operating at the nominal frequency, a transient frequency of 2 Hz shall be applied of which not more than 1⁄2 cycle per second is ing at the nominal frequency, a transient frequency of 2 Hz shall be superimposed.

S27.12 **Temperature**—The equipment shall be capable of normal operation (without alignment or adjustment) other than the accessible controls employed for operation of the equipment throughout the following temperature cycle; tolerances in operating characteristics shall be as specified in the individual equipment specification.

1. Hold room temperature at 0 ± 2°C (32 ± 3.6°F) for at least 24 h.
2. Increase room temperature in steps of 10°C (18°F) each, at 30 min per step, until 65 ± 2°C (149 ± 3.6°F) is reached, and hold at that temperature for at least 4 h.
3. Reduce room temperature in steps of 10°C (18°F) each, at 30 min per step, until 25 ± 2°C (77 ± 3.6°F) is reached, and hold at that temperature for at least 4 h. At each temperature plateau 0°C (32°F), 65°C(149°F) and 25°C (77°F), a reference measurement (see S27.3) shall be made. Performance shall conform to S24.12.

S27.13 **Insulation Resistance**—The insulation resistance of the equipment shall be determined by applying 50 V dc between electrical input and output circuits and between these circuits and ground (see S24.13).

S27.14 **Vibration**—The equipment shall be tested in accordance with type I (environmental vibration) of MIL-STD-167-1 except that the upper limit of the frequency range shall be 100 Hz. The amplitudes of vibration shall be in accordance with Table S4. If no resonances are observed, the 2 h endurance test shall be conducted at 100 Hz. During the vibration test, an input equal to 80 ± 5 % of the temperature span shall be applied to the test sample. The output during the test shall be monitored. Performance shall conform to S24.14.

S27.15 **Shock**—The shock test shall be conducted in accordance with MIL-S-901, grade A, class I, type C. During the test an input equal to 80 ± 5 % of the temperature span shall be applied to the equipment. The test sample output during the test shall be monitored. Before and after this test, reference measurements shall be made for comparison (see S27.3). Performance shall conform to S24.15.

**S28. Inspection**

The testing set forth in this specification shall become a part of the manufacturer’s overall inspection system or quality program. The manufacturer’s quality system shall comply with the requirements of ANSI/ASQC 9001-1994, Quality Systems—Model for Quality Assurance in Design, Development, Production, Installation, and Servicing. Certification and registration is highly desired but not required.

S28.1 **Classification of Inspections**—The inspection requirements specified herein are classified as follows:

1. Qualification testing, and
2. Quality conformance testing.

S28.2 **Test Conditions**—Except where the following factors are the variables, the tests shall be conducted with the equipment operating under the following conditions:

1. Ambient temperature shall be 24 ± 5°C (75 ± 9°F),
2. Relative humidity shall be 60 ± 15 %,
3. Supply voltage shall be nominal, and
4. Supply frequency shall be nominal.

S28.3 **Qualification Testing**—The qualification testing shall consist of the tests specified in Table S5. The tests shall be performed in the sequence shown.

S28.3.1 **Sample Size**—The number of samples subjected to qualification tests as specified in Table S5 shall depend on the equipment design. If each range is covered by a separate and distinct design, a sample for each range will require testing. Only one sample of a basically similar design series which may

cover many ranges need be tested if mechanical and electrical similarity is deemed sufficient by the purchaser.

S28.4 Quality Conformance Testing—All temperature measurement equipment offered for delivery shall be subjected to the examination and tests listed in Table S6 and shall be conducted in the order listed. Failure of any temperature equipment to meet the requirements of this specification shall be cause for rejection.

S29. Certification

S29.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data remain on file for three years at the manufacturer’s facility for review by purchaser upon request.

S30. Product Marking

S30.1 Product marking requirements shall be specified in the acquisition requirements but at a minimum, shall include:

1. Manufacturer’s name,
2. Classification, and

S31. Packaging and Package Marking

S31.1 Packaging and package marking shall be in accordance with Section 15.

THERMOCOUPLE AND RESISTANCE TEMPERATURE DETECTOR ASSEMBLIES (NAVAL SHIPBOARD USE)

The following appendix to supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard (ASTM F 2362) and this supplement’s appendix, the requirements of this supplement’s appendix shall take precedence for equipment acquired by this supplement’s appendix. This document supersedes MIL-T-24388, Thermocouple and Resistance Temperature Detector Assemblies, General Specification for (Naval Shipboard), for new ship construction.

S32. Scope

S32.1 This specification covers environmentally hardened resistance thermometers and thermocouple sensors that transform the surrounding thermal energy in a manner that can be electrically measured and converted to a temperature using a signal conditioner/temperature monitor. Types of configurations covered in this specification are those which place the resistance thermometer or thermocouple sensor directly into the medium (bare bulb), into a thermowell, or embedded into a bearing.

S32.2 Resistance thermometers and thermocouple sensors are intended to convert temperature measured to an electrical output for input to a temperature signal conditioner.

S32.3 The U.S. Government preferred system of measurement is the metric SI system. However, since this item was originally designed using inch-pound units of measurement, in the event of conflict between the metric and inch-pound units, the inch-pound units shall take precedence.

S33. Referenced Documents

E 344 Terminology Relating to Thermometry and Hydrometry
S34. Terminology

S34.1 Definitions—Definitions and terminology shall be in accordance with Terminology E 344.

S35. Classification

S35.1 Design Type—Resistance thermometers and thermocouple sensors shall be classified according to the following variables:

Example: ASTM F2362S32-KTC-TW-S7

<table>
<thead>
<tr>
<th>Specification Type</th>
<th>Configuration Type</th>
<th>Designation Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>F2362S32</td>
<td>(see S35.2)</td>
<td>S7</td>
</tr>
<tr>
<td></td>
<td>TW</td>
<td>(see S35.4)</td>
</tr>
</tbody>
</table>

S35.2 Type—The type of resistance thermometer or thermocouple sensor shall be designated by one of the following three-letter symbols:

Type

- Type K thermocouple sensor
- Resistance thermometer with nickel element
- Resistance thermometer with platinum element

Symbols

- KTC
- NRT
- PRT

S35.3 Configuration—Type of configuration for which the resistance thermometer or thermocouple sensor is intended shall be designated by one of the following two-letter symbols:

<table>
<thead>
<tr>
<th>Type of Configuration</th>
<th>Symbols</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thermowell</td>
<td>TW</td>
</tr>
<tr>
<td>Bare bulb</td>
<td>BB</td>
</tr>
<tr>
<td>Embedded</td>
<td>EM</td>
</tr>
</tbody>
</table>

S35.4 Designation Number—The designation number used to specify the sheath length and other applicable parameters within each type of configuration shall be denoted by one or two numerals or by one or two numerals preceded by a letter found in one of the following:

<table>
<thead>
<tr>
<th>Type of Configuration</th>
<th>Table Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>TW</td>
<td>S7</td>

<td>S9</td>
</tr>
</tbody>
</table>

S36. Ordering Information

S36.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with S36.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S36.2 Acquisition Requirements—Acquisition documents should specify the following:

1. Title, number, and date of this specification,
2. Classification required,
3. Design type,
4. Range,
5. Quantity required,
6. When qualification testing is required,
7. Disposition of qualification test samples,
8. Product marking requirements, and
9. Packaging requirements.

S37. Materials and Manufacture

S37.1 Materials—Recommended materials of resistance thermometer and thermocouple sensor components are provided in Table S7.

S37.1.1 Nonmetallic Materials—Nonmetals, when used for seals, protective finishes, and so forth, shall be moisture and flame resistant, shall not support fungus growth, and shall not be adversely affected by the ambient environments specified in the performance requirements of this specification.

S37.1.2 Connecting Wire and End Closure—The connecting wire and end closure shall be airtight, nonhygroscopic, fungus resistant, flame resistant, and able to form a chemical bond with connecting wires (thermowell configuration), electrical connector receptacle pins, (bare bulb configuration), or the connecting wire insulation (embedded configuration) and with the sheath sufficient to meet the sealing requirements. The connecting wire end closure shall not chemically react, degrade, or outgas when subjected to the following: air, distilled water, sea water, salt, petroleum and silicone based oils, oil solvents, prolonged (greater than 1 month) periods of exposure to ambient temperatures, prolonged periods of exposure to elevated temperatures up to 205°C (400°F), and exposure to prolonged cycling periods from ambient to elevated temperatures. A connecting wire and enclosure consisting of a ceramic-to-metal or a glass-to-metal seal shall also incorporate other characteristics to make it impenetrable to fluids and shall be considered a hermetic seal. The connecting wire end closure shall meet all the performance requirements specified in S39, including the connecting wire end closing requirement (see S42.8).
S37.1.3 **Fungus-inert Materials**—Materials which provide a nutrient medium for fungus and insects shall not be used in the construction of any resistance thermometer or thermocouple sensor.

S37.1.4 **Restricted Materials**—Cadmium or cadmium-plated parts shall not be used.

### S38. Physical Properties

**S38.1 Construction**—Resistance thermometers and thermocouple sensors are shown on Figs. S1-S6. Resistance thermometer and thermocouple sensor construction dimensions and application temperatures for thermowell, bare bulb, and embedded configurations shall be in accordance with Table S8, Table S9, and Table S10 respectively.

**S38.1.1 Resistance Thermometer**—Resistance thermometers have the following characteristics:

1. The two resistance thermometer elements have different temperature ranges (excluding the EM configuration):
   - Nickel: -40 to 205°C (-40 to 400°F)
   - Platinum: -40 to 538°C (-40 to 1000°F)
2. High accuracy,
3. Excellent stability and reproducibility but slow in response,
4. Easily interchangeable but damages easily if not handled properly. Can be matched to close tolerances for temperature difference measurements, and
5. Resistance thermometers with platinum elements should be specified for new construction and new instrument installations. Resistance thermometers with nickel elements should be restricted to retrofit and replacements only.

**S38.1.2 Thermocouple Sensors**—Thermocouple sensors have the following characteristics:

1. Simple construction,
2. Small signal output is produced which requires sensitive measuring instruments,
3. Lower cost and faster response than the resistance thermometer,
4. Type K thermocouple covers a temperature range of -40 to 816°C (-40 to 1500°F) (excluding EM configuration),
5. Compensation for reference junction temperature is required,
6. Attains high accuracy but subject to changes within the accuracy limit with use. These changes become more pronounced as the temperature increases.

</table>
Preferable for use with thermowells having a 5.08 cm (2 in.) immersion depth since the thermocouple sensor’s minimum immersion depth is significantly smaller than that of a resistance thermometer, and

Note—Dimensions and tolerances are reference only to meet installation requirements.

**FIG. S1 Resistance Thermometer/Thermocouple Sensor Construction**

(1) Dimension to suit particular head design.

(2) Inside diameter shall be sized to allow clearance for sensor sheath, spring stop, and spring.

(3) Minimum wall thickness shall be 0.109 in..

**FIG. S2 Connection Head Extension**

(7) Preferable for use with thermowells having a 5.08 cm (2 in.) immersion depth since the thermocouple sensor’s minimum immersion depth is significantly smaller than that of a resistance thermometer, and
Preferable for use in the EM configuration since extremely fine resistance thermometer element wire is very susceptible to electrical opens, shorts, or intermittent behavior in service.

S38.2 New Construction—Resistance thermometers with platinum elements should be specified for new construction and new instrument installations with the following exceptions:

(1) Thermowells have a 5.08 cm (2 in.) immersion depth, see S38.1.2(7), and

(2) EM configuration installations, see S38.1.2(8).

S38.2.1 Resistance Thermometer Element:

S38.2.1.1 Location—The resistance thermometer element shall be located within the bottom 2 in. of sheath for the thermowell and bare bulb configurations. The resistance thermometer element for all configurations shall be located in a manner such that the installation resistance test requirements are met.

S38.2.1.2 Resistance Thermometer Current—Resistance thermometers shall withstand a continuous operating current of 6 milliamperes (mA) direct current (dc).

S38.2.1.3 Temperature versus Resistance—Relationships for resistance thermometers shall be in accordance with Table S11 and Table S12 with limits of error specified in S39.2.

S38.2.2 Thermocouple:

S38.2.2.1 Location—The thermocouple measuring junction shall be ungrounded and located within the bottom 6.35 mm (¼ in.) of the sheath for the thermowell and bare bulb configurations. The thermocouple measuring junction shall be
S38.2.2 Connecting Wires—The diameter of the connecting wire shall be the AWG as specified in Table S7. The connecting wire material shall also be in accordance with Table S7.

S38.2.3 Resistance Thermometers:
S38.2.3.1 External Insulation (TW and EM Configurations)—The material for the external insulation shall be specified in Table S7.
S38.2.3.2 Color Code—The external insulation for the single connecting wire attached to one end of the resistance ungrounded and located in the middle of the sheath for the embedded configuration.
thermometer element shall be color coded red. The external insulation for the two connecting wires attached to the other end of the resistance thermometer element shall be color coded white or amber.

S38.2.3.3 Internal Insulation (TW and BB Configurations)—The resistance thermometer connecting wires shall be insulated from the sheath and from each other by alumina (A12O3). The alumina shall be alpha alumina with a minimum content of 99.5% alumina. Sulfur shall not exceed 50 parts per million (ppm) while carbon shall not exceed 200 ppm.

S38.2.3.4 Number of Connecting Wires—The resistance thermometers shall be of three-wire construction except for the bare bulb configuration with a nickel element which shall be of two-wire construction.

S38.2.4 Thermocouple Sensors:
S38.2.4.1 External Insulating (TW and EM Configurations)—The material for external insulation shall be as specified in Table S7.
S38.2.4.2 Color Code—The external insulation for the positive (chromel) connecting wire shall be yellow. The external insulation for the negative (alumel) connecting wire shall be red.

FIG. S5 Bare Bulb Type Resistance Thermometer/Thermocouple

S38.2.4.3 Internal Insulation (TW and EM Configurations)—The thermocouple sensor connecting wires shall be insulated from each other, except at the measuring junction, and from the sheath by magnesia (MgO). The magnesia shall be electrically fused with a 96.5% minimum content of magnesia. The sulfur content shall be less than 50 ppm and the carbon content less than 200 ppm.

S38.2.5 Thermowell Configuration:
S38.2.5.1 Temperature Exposures—Maximum connecting head temperature shall be 300°F for resistance thermometers with nickel elements, 260°C (500°F) for resistance thermometers with platinum elements, and 260°C (500°F) for type K thermocouple sensors.
S38.2.5.2 Watertight Enclosure—Resistance thermometers and thermocouple sensors shall be watertight such that water directed at the sensor from any angle is prevented from entry.
S38.2.5.3 Construction—Thermowell configuration shall consist of resistance thermometer or thermocouple sensor, construction head, and a connection head extension as shown of Figs. S1-S4.
S38.2.5.4 Connection Head Cap—The connection head of the thermowell configuration shall be provided with a screw-on type cap with metal link chain.
S38.2.5.5 Terminal Board—Terminal board shall be secured to the connection head.

S38.2.5.6 Thermowells—When resistance thermometers and thermocouple sensors are intended for use with thermowells, the thermowells shall be in accordance with ASME B40.9, Supplement 1.

S38.2.6 Bare Bulb Configuration:

S38.2.6.1 Temperature Exposures—The maximum connector receptacle and plug temperature shall be 149°C (300°F).

S38.2.6.2 Watertight Enclosure—Resistance thermometers and thermocouple sensors shall be watertight such that water directed at the sensor from any angle is prevented from entry.

S38.2.6.3 Construction—The bare bulb configuration shall be of one-piece construction as shown on Fig. S5.

S38.2.6.4 End Cap—The connector receptacle shall be provided with a screw-on end cap.

S38.2.6.5 Pressure Requirements—The resistance thermometer and thermocouple sensor shall withstand 37.9 MPa (5500 psi) when inserted into air stream at a temperature of 182°C (360°F) with velocity of 12.2 m (40 ft) per second.

S38.2.7 Embedded Configuration:

S38.2.7.1 Temperature Exposures—Resistance thermometers and thermocouple sensors shall withstand a maximum temperature of 205°C (400°F) for continuous use, 274°C (525°F) for short term exposure of 15 min, and 288°C (550°F) for short term exposure of 2 min.

S38.2.7.2 Construction—The embedded configuration shall consist of the resistance thermometer or thermocouple sensor as shown in Fig. S6.

S38.2.7.3 Scoring—The material and construction of the resistance thermometer or thermocouple sensor shall be such that in the event the bearing should fail and be wiped to a depth of 2.54 ± 254 μm (0.10 ± 0.01 in.) over the area of the resistance thermometer or thermocouple sensor, scoring of a carbon steel shaft having a Brinell hardness of 170 to 180 will be limited to a depth of 7.62 μm (300 μin.) or less.

S38.2.7.4 Babbitt Topping—The tip of the sheath shall contain a 2.54 ± 1.5 mm (0.10 ± 0.06 in.) thick topping of babbitt. The diameter, including maximum to tolerance, of the babbitt topping shall conform to the diameter of the sheath.

S38.2.8 Cleaning and Surface Finishes—Surface of castings, forgings, molded parts, stampings, machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids, and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surface shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change due to heat from welding operation. There shall be no damage to adjacent parts resulting from the welding.

S39. Performance Requirements

S39.1 Insulation Resistance—The insulation resistance shall be determined at 50 VDC and shall be no less than 10 megohms.

S39.2 Accuracy—The span and limits of error shall be as specified in Table S13 (see S42.2).

S39.2.1 Accuracy Repeatability—The span and limits of error shall be as specified in Table S14.

S39.2.2 Reference Measurement—The performance shall conform to S39.2 (see S42.2.2).

S39.3 Response Time—Response time of the resistance thermometers and thermocouple sensors shall be as follows:

(1) 8 s or less for thermowell configuration,

(2) 15 s or less for bare bulb configuration, and
(3) 5 s or less for embedded configuration.

**S39.4 Self-heating (Resistance Thermometers only)**—The temperature change due to self heating of the resistance thermometers shall not exceed 0.6°C (1.1°F) at an input power level of 5 milliwatts (see S42.4).

**S39.5 Thermal Cycling**—When subjected to 1500 thermal cycles, there shall be no shorts, opens, or evidence of intermittent behavior. The reference thermometers and the thermocouple sensors shall show no evidence of physical damage as result of thermal cycling. The reference measurement performed at the conclusion of the thermal cycling shall conform to S39.2.

**S39.6 Over-temperature (EM Configuration)**—Resistance thermometers and thermocouple sensors shall conform to the temperature span and accuracy requirements specified in S39.2 after being subjected to over-temperature. During over-temperature, there shall be no shorts, opens, or evidence of intermittent behavior. The reference measurement performed at the conclusion of over-temperature shall conform to S39.2 (see S42.5).

**S39.7 Terminal Strength (TW and EM Configurations)**—Attachment of connecting wires to the connecting wire end closure and their encapsulation into the sheath shall withstand the specified static load. The resistance thermometers and thermocouple sensors shall be axially loaded for 15 min without causing circuit failure or loss of watertight integrity.
shall be no observed evidence of air bubbles while under vacuum or pressure, there shall be no physical damage to the sensors. After application of vacuum and pressure, the performance of the resistance thermometers and thermocouple sensors shall conform to S39.1 and S39.2 (see S42.8).

S39.9 Enclosure (TW and BB configurations)—There shall be no leakage of water into the watertight enclosure (see S42.9).

S39.10 Salt Spray—Resistance thermometers and thermocouple sensors shall show no appreciable corrosion or other damage when subjected to salt spray (S42.10). The performance of the resistance thermometers and thermocouple sensors shall conform to S39.1 and S39.2.

S39.11 Spring Loading (TW Configuration)—When compressed 7.62 cm (3/16 in.), the spring shall exert a minimum force of 2.27 kg (5 lb) (S42.11).

S39.12 Vibration—When exposed to vibration per MIL-STD-167-1, the resistance thermometers and thermocouple sensors shall show no evidence of improper operation, failure, or damage (see S42.12). The electrical signal from the resistance thermometer and thermocouple sensor shall be monitored during vibration and there shall be no shift in the temperature indication. A reference measurement performed at the conclusion of vibration shall meet the specified accuracy requirements of S39.2.

S39.13 Shock—Resistance thermometers and thermocouple sensors shall withstand the effects of shock in accordance with MIL-S-901 (S42.13). A reference measurement performed after exposure to shock shall meet the specified accuracy requirements of S39.2.

(see S42.7). The reference measurement performed at the conclusion of static loading shall conform to S39.2.

S39.8 Connecting Wire and Closure—When subjected to a vacuum or pressure, there shall be no physical damage to the resistance thermometers and thermocouple sensors and there shall be no observed evidence of air bubbles while under vacuum. After application of vacuum and pressure, the performance of the resistance thermometers and thermocouple sensors shall conform to S39.1 and S39.2 (see S42.8).
S39.14 Pressure (EM Configuration)—The embedded resistance thermometers and thermocouple sensors shall not deform to such a degree that the babbitt surface is visually determined to be dimpled, cracked, or ruptured after exposure to a pressure of 12.4 MPa (1800 lb/in.²) gauge. The insulation resistance between each connecting wire and the babbitt surface shall be no less than 10 megohms when measured both before and at the conclusion of exposure to pressure. The resistance thermometers and thermocouple sensors shall meet the reference measurement requirements of S39.2 both before and at the conclusion of exposure to pressure (S42.14).

S39.15 Scoring (EM Configuration)—The stylus traces resulting from the application of a scoring force of 3.63 kg (8 lb) shall not indicate a scoring depth exceeding 7.62 micrometers (300 microinches) (S42.15).

S40. Workmanship, Finish, and Appearance

S40.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, and welded parts shall be free of defects such as cracks, porosity, undercuts, voids and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change due to heat from welding operation. There shall be no damage to adjacent parts resulting from welding.

S41. Number of Tests and Retests

S41.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S42. Test Methods

S42.1 Insulation Resistance—Insulation resistance shall be determined by applying 50 V (dc) between the connecting wires and the sheath. Performance shall conform to S39.1.

S42.2 Accuracy—Resistance thermometers and thermocouple sensors shall be calibrated in accordance with the requirements of S39.2. The temperature of the bath fluid shall be as shown in Table S15, ±2.8°C (5°F), with a temperature gradient of ±0.06°C (½°F) for salt bath, under steady state temperature conditions. The resistance thermometers and thermocouple sensors shall be calibrated at temperatures listed in the increasing order. Performance shall conform to S39.2.

S42.2.1 Accuracy Repeatability—The accuracy test specified in S42.2 shall be performed two additional times. Performance shall conform to S39.2.1.

A These values shall be used for reference measurement (see S42.2.2).

S42.2.2 Reference Measurement—The accuracy test as specified in S42.2 shall be referred to as a “reference measurement” when performed at the conclusion of another test listed in Table S15. The reference measurement shall only be conducted at the temperatures that are specified for a reference measurement in Table S15. Performance shall conform to S39.2.2.

S42.3 Response Time—Resistance thermometers and thermocouple sensors shall be tested in accordance with the conditions of Table S16. The low or high temperature test shall be used depending upon the configuration and the type of resistance thermometer or thermocouple sensor criteria in Table S17. The time it takes the standard cylinder output to rise from an equivalent temperature from T₁ to T₂ in Table S16 shall be the standard cylinder response time. The standard cylinder response time shall be within the values listed in Table S16 for at least six consecutive trials not counting those performed in establishing the proper temperature bath conditions (temperature, orientation, stirrer speed, and so forth). The response time of the resistance thermometers and thermocouple sensors shall be the average of at least six readings taken during at least six consecutive trials where the standard cylinder was within the values specified in Table S16. The test conditions of the resistance thermometers and thermocouple sensors are also those contained in Table S17. Performance shall conform to S39.3.

S42.3.1 Standard Cylinder—A standard cylinder shall be used for this test. The information needed to construct a standard cylinder is provided on Fig. S7. Connecting wires from the standard cylinder thermocouple shall terminate at an ice bottle, ice point reference junction or a reference junction compensated electronic indicator. If an ice bottle or ice point reference junction is used, the extension wires coming from the reference junction shall be connected to an indicator such as a potentiometer or a millivolt recorder. No matter what form of indicator is used, the indicator shall have a response time not less than two times faster than the response time of the temperature rise that the standard cylinder will measure (see Table S16). Response time measurement shall be conducted using either a stop watch or any method capable of timing to 0.2 s or better.

S42.3.2 Temperature Bath—Two temperature baths are used in performing this test. The baths shall be sufficiently large or constructed in such a manner that the temperature bath fluid will not be cooled by greater than 0.5 % of the span when either the cylinder or the filled system thermometer is immersed. The “hot” bath shall contain a variable speed stirrer. Two liquid temperature bath fluids and temperatures are

</table>
permissible for use with this test and are specified in Table S16. One fluid temperature is referred to as the “cold bath temperature”, while the other is referred to as the “hot bath temperature.”

S42.3.3 Set Up—The conditions in the hot temperature bath fluid shall be set up such that the standard cylinder response time will be within the limits specified in S39.3. Hot temperature bath fluid conditions and, thus, the standard cylinder response time, will be changed by varying the stirring parameters. The standard cylinder shall be immersed in the temperature bath fluid to the bottom of the standard cylinder collar (see Fig. S7 for location). The standard cylinder shall always be immersed in the hot temperature bath fluid in the same location and in the same orientation. The immersion depth of the standard cylinder thermocouple measuring junction and the immersion depth of the embedded configuration resistance thermometer or thermocouple sensor shall be maintained at the same level.

S42.3.4 Determining Response Time—The resistance thermometer or thermocouple sensor (or standard cylinder) shall be immersed in the hot temperature bath until there is no further indication of temperature rise. The resistance thermometer or thermocouple sensor (or standard cylinder) shall then be immersed in the cold temperature bath until there is no further indication of temperature decrease. The resistance thermometer or thermocouple sensor (or standard cylinder) shall again be immersed in the hot temperature bath. Timing shall be started when the resistance thermometer or thermocouple (or standard cylinder) indicator reaches temperature $T_1$ (see Table S16) and stopped when temperature $T_2$ is reached. The time it takes the resistance thermometer or thermocouple (or standard cylinder) to indicate the difference between temperatures $T_1$ and $T_2$ shall be defined as the response time.

S42.3.5 Conducting Response Time Test—The response time test shall be conducted by taking alternate response time measurements between the standard cylinder and the thermometer. Each alternation of the standard cylinder’s then the thermometer’s response time measurements shall be defined as a trial.

S42.4 Self-heating (Resistance Thermometers)—The self-heating test shall be conducted in a water bath under the conditions specified in S42.2. A resistance thermometer shall be immersed in the water bath to at least the minimum immersion depth and allowed to stabilize at 82°C (180°F). A series of direct currents shall be passed through the resistance thermometer elements and maintained until steady state is attained such that the power impact is successively 0.5, 1.0, 3.0, and 5.0 milliwatts. A curve of the indicated temperature versus power input shall be plotted and extrapolated to zero power input. The difference between the indicated temperature at 5 milliwatts input and the extrapolated value at the indicated temperature at zero power input is the effect due to self heating. Performance shall conform to S39.4.

S42.5 Thermal Cycling—Resistance thermometers and thermocouple sensors shall be heated and cooled for 1500 cycles in accordance with Table S18. Cycle rate shall not exceed two cycles per minute. The output of the resistance thermometers and thermocouple sensors shall be monitored during thermal cycling. Connection head temperature shall not exceed the maximum connection head temperature specified in Table S7. Prior to and following the test, a reference measurement as specified in S42.2.2 shall be conducted. Performance shall conform to S39.5.

S42.6 Over-temperature (EM Configuration)—Resistance thermometers and thermocouple sensors, while at ambient temperature, shall be quickly (within 2 s) immersed for a period of 15 ± 0.5 min in a temperature bath in which the fluid is stabilized to a temperature of 274 ± 2.8°C (525 ± 5°F). The resistance thermometer or thermocouple sensor immersion depth shall be 7.62 cm (3/4 in.) if not installed in a fixture. If the resistance thermometer or thermocouple sensor is installed in a fixture, it shall be immersed to a sufficient depth to provide an accurate bath temperature measurement. The resistance thermometers or thermocouple sensors shall then be quickly immersed in another temperature bath containing the same fluid stabilized at a temperature of 288 ± 2.8°C (550 ± 5°F) to the specified depth for a period of 2 ± 0.05 min. The resistance thermometers or thermocouple sensors shall then be quickly immersed in the first temperature bath in which the fluid is stabilized at a temperature of 274 ± 2.8°C (525 ± 5°F) to the specified depth for a period of 15 ± 0.5 min. The output of the resistance thermometers or thermocouple sensors shall be monitored during this test. The resistance thermometers or thermocouple sensors shall reach the bath fluid temperature within 1 min after immersion into a temperature bath whether or not a text fixture is used. A reference measurement shall be performed at the conclusion of this test. Performance shall conform to S39.6.

S42.7 Terminal Strength (TW and EM Configurations)—With the resistance thermometers and thermocouple sensors firmly held in a holding fixture, a static tensile load of 2.27 kg (5 lb) shall be applied to each connecting wire simultaneously for 15 min for the thermowell configuration. For the embedded configuration, a static tensile load of 2.27 kg (5 lb) shall be applied to each connecting wire separately. The direction of the load shall be along the longitudinal axis of the resistance thermometers and thermocouple sensors. A reference measurement shall be performed at the conclusion of this test. The performance shall conform to S39.7.

S42.8 Connecting Wire End Closure—During this test, the resistance thermometers and thermocouple sensors of the thermowell configuration shall be removed from the connection head. No end cap shall be threaded over the connector receptacle of the resistance thermometers and thermocouple sensors of the bare bulb configuration. Connecting wire end closure shall meet the requirements specified in S39.8.

S42.8.1 Vacuum Portion—The desiccator shall be half filled with water and evacuated of dissolved air. The resistance
thermometers and thermocouple sensors shall be immersed in this desiccator. The desiccator shall then be subjected to an absolute pressure of 27.5 kPa ± 3.5 kPa (4.0 ± 0.5 lb/in.²) for 15 min. The connecting wire end closure shall be observed for evidence of air leaks.

S42.8.2 Pressure Portion—The resistance thermometers and thermocouple sensors shall be placed inside a pressure

</table>
chamber and the pressure chamber shall be hydrostatically pressurized with water to 172.4 ± 3.5 kPa (25 ± 5 lb/in.²) for a period of no less than 15 ± 0.5 min.

S42.8.3 Post Test Measurements—At the conclusion of this test, an insulation resistance test followed by a reference measurement shall be performed. Performance shall conform to S39.8.

S42.9 Enclosures (TW and BB Configurations)—The resistance thermometers and thermocouple sensors of the thermowell configuration shall be tested with the thermowell attached to the connection head extension and a threaded plug inserted into the connection head conduit connection. The resistance thermometers and thermocouple sensors of the bare bulb configuration shall be tested with an end cap threaded over the connector receptacle. The test shall consist of a solid stream of water from a 2.54 cm (1 in.) diameter nozzle at a rate of 246 L (65 gal) per minute. The stream shall be directed on all surfaces of the equipment and its mounting surface from a maximum distance of 3.048 m (10 ft) and for a minimum of 60 min.

S42.10 Salt Spray—Resistance thermometers and thermocouple sensors shall be subjected to the salt spray test in accordance with ASTM B 117. The salt spray test shall run for a duration of 96 h. The salt solution shall be 5 ± 1% concentration (5 parts by weight of salt in 95 parts by weight of water). At the conclusion of this test, an insulation resistance test followed by a reference measurement shall be performed. Performance shall conform to S39.10.

S42.10.1 Thermowell Configuration—The resistance thermometer or thermocouple sensor shall be removed from the connection head when the test has reached the 48 h point. A plug shall be threaded into the connection head conduit connection (see Fig. S3) and a thermowell shall be threaded onto the connection head extension. The connection head (including connection head extension, plug, and thermowell) and the resistance thermometer or thermocouple sensor shall be separately subjected to the salt spray test.

S42.10.2 Bare Bulb Configuration—The resistance thermometers and thermocouple sensors shall be subjected to the salt spray test without an end cap threaded over the connector receptacle.

S42.11 Spring Loading (TW Configuration)—Resistance thermometers and thermocouple sensors shall be mounted in a jig and compressed 7.62 cm (3 in.) three successive times. The compressive force of the spring shall be measured. Performance shall conform to S39.11.

S42.12 Vibration—The vibration test shall be in accordance with MIL-S-901 grade A, class I, type C for lightweight equipment. Resistance thermometers and thermocouple sensors shall be mounted to simulate actual installation. Resistance thermometers and thermocouple sensors shall be mounted no less than 7.62 cm (3 in.) from the side and 7.62 cm (3 in.) from the rear of the platform. Output during the test shall be monitored. A reference measurement shall be performed at the conclusion of this test. Performance shall conform to S39.12.

S42.12.1 Exploratory Test:

(1) Maintain each discrete frequency from 5 to 100 Hz at 1 Hz intervals for a minimum of 15 s, or a sweep rate that shall not exceed 4 Hz per minute.

(2) Displacement or acceleration shall be as specified in Table S19.

(3) Frequencies and locations where resonance occurs during this test shall be noted.

S42.12.2 Variable Frequency Test:

(1) Discrete frequency interval of 1 Hz.

(2) Frequency range 5 to 100 Hz.

(3) Each discrete frequency shall be maintained for a minimum of 5 min.

(4) Displacements shall be as specified in Table S19.

(5) Frequencies and locations where resonance occurs during this test shall be noted.

S42.12.3 Endurance Test:

(1) The resistance thermometers and thermocouple sensors shall be subjected to a 2-h endurance run at each resonance.

(2) Displacement or acceleration shall be the variable frequency test values specified in Table S19.

(3) If no resonance is found, a 2-h performance run shall be performed at 100 Hz. A reference measurement shall be performed after the conclusion of the vibration test. Performance shall conform to S39.12.

S42.13 Shock—Shock tests shall be in accordance with MIL-S-901 grade A, class I, type C for lightweight equipment. Resistance thermometers and thermocouple sensors shall be mounted to simulate actual installation. Resistance thermometers and thermocouple sensors shall be mounted no less than 7.62 cm (3 in.) from the side and 7.62 cm (3 in.) from the rear of the platform. Output during the test shall be monitored. A reference measurement shall be performed at the conclusion of this test. Performance shall conform to S39.13.

S42.14 Pressure (EM Configuration)—The resistance thermometers and thermocouple sensors under test, which will be used only for this one test, shall be installed in a fixture made from mild steel. The critical dimensions to which the fixture shall conform are shown in Fig. S7. The entire counterbored 1.9 cm (⅝-in.) diameter surface shall be babbitted over, using babbitt that conforms to grade 2 of Specification B 23, flush with the top of the test fixture. The insulation resistance between each connecting wire and the babbitt surface shall then be measured. The babbitt surface shall then be exposed to a pressure of 12.4 MPa (1800 ± 10 lb/in.²) for 5 ± 0.25 min. After completion of this test, the insulation resistance shall be measured in the same manner as before the test. The fixture shall be unbabbitted and a reference measurement shall be performed. Performance shall conform to S39.14.

S42.15 Scoring—The resistance thermometers and thermocouple sensors under test, which will be used only for this one test, shall be installed in a fixture made from mild steel. The critical dimensions to which the fixture shall conform are shown in S39. The resistance thermometers and thermocouple sensors under test shall not contain a babbitt topping, and the connecting wire shall be severed. The entire 1.9 cm (¾ in.) diameter counterbored surface shall be babbitted over using babbitt that conforms to Grade 2 of Specification B 23 with 3 mm ± 254 µm (0.12 ± 0.01 in.) of the resistance thermometers and thermocouple sensors protruding above the babbitt surface. The protruding tip of the resistance thermometers and thermocouple sensors shall be brought into contact with a 5.08 cm ± 254 µm (2.00 ± 0.01 in.) diameter shaft that is rotating at 3000 ± 30 r/min. The shaft shall be made from carbon steel having a Brinell hardness between 170 and 180 and a surface finish between 15 and 25 root mean square (rms). A force of 3.63 kg ± 454 g (8 ± 1 lb.) shall be applied to the resistance thermometers and thermocouple sensors to ensure contact with the circumference of the shaft during the test. The resistance thermometers and thermocouple sensors shall be oriented so that the axis perpendicular to their sensor tip face shall intersect and be perpendicular to the longitudinal axis of the shaft. Prior to the start of the test, the shaft and the fixture shall be cleaned with a suitable solvent and wiped dry. A stylus trace of the shaft surface parallel to the axis of the shaft shall be performed at six equally spaced intervals around the circumference of the shaft. No lubrication shall be used between the resistance thermometers and thermocouple sensors and the shaft during the scoring test. The rotating shaft shall remove 2.54 mm ± 254 µm (0.10 ± 0.10 in.) of material from the protruding tip of the resistance thermometers or thermocouple sensors. Upon completion of the test, removal of any babbitt from the surface of the shaft shall be accomplished by the use of 20% sodium hydroxide solution. A stylus trace of the shaft surface parallel to the axis of the shaft shall be performed at the same six equally spaced intervals around the circumference of the shaft. Performance shall conform to S39.15.

S43. Inspection

S43.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

1. Qualification testing, and
2. Quality conformance testing.

S43.2 Qualification Testing:

S43.2.1 Sample Size—Unless otherwise specified, two resistance thermometers and thermocouple sensors of each configuration and range shall be subjected to qualification testing.

S43.2.2 General Examination and Tests—Qualification inspection shall consist of the general examination and tests specified in Table S20 in the order listed. Any deviation in the test order shall first be approved by the purchaser.

S43.2.3 Acceptance Criteria—The resistance thermometers and thermocouple sensors shall meet all the requirements of the general examination and tests listed in Table S20.

S43.3 Quality Conformance Inspection:

S43.3.1 Inspection Lot—An inspection lot shall consist of all resistance thermometers and thermocouple sensors of the same classification, produced under essentially the same conditions and offered for delivery at the same time.

S43.3.2 Group A General Examination and Test—Resistance thermometers and thermocouple sensors in each lot shall be subjected to the group A general examination and test specified in Table S20 in the order listed.

S43.3.3 Group B General Examination and Test—A sample resistance thermometer and thermocouple shall be randomly selected from each lot of 100 or more units, as appropriate, for the tests specified in Table S20. Group B tests shall be performed in the order listed on resistance thermometers and thermocouple sensors that have passed group A tests.

S43.3.4 Acceptance Criteria:

S43.3.4.1 Acceptance Criteria for Group A—The resistance thermometers and thermocouple sensors shall meet all the requirements of the group A general examination and tests in order to receive group A quality conformance inspection approval.

S43.3.4.2 Acceptance Criteria for Group B—Selected resistance thermometers and thermocouple sensors shall have passed the group A tests. If any resistance thermometer or thermocouple sensor fails in any test, no resistance thermometer or thermocouple sensor shall be accepted for quality conformance inspection until the contractor has determined the cause of the defect and has taken the necessary action to correct or eliminate the defects from resistance thermometers or thermocouple sensors on hand. The failed test and any other test required shall be repeated to demonstrate that the corrective action will enable the resistance thermometers or thermocouple sensors to conform to the requirements of this specification.

S43.4 Test Conditions—Except where the following factors are variables, the tests in this specification shall be conducted under the following conditions:

1. Calibration bath temperature shall be plus or minus 2.8°C (5°F) from the specified temperature.

</table>
(2) Resistance thermometer element excitation current shall be 1.0 ± 0.1 mA dc.

(3) Maximum immersion into the temperature bath shall be as follows:
   (a) TW configuration—Immersion shall be to the thermowell insertion length minus 1.27 cm (0.5 in.).
   (b) BB configuration—Immersion shall be to the “E” dimension minus the thread length 2.23 cm (0.875 in.).
   (c) EM configuration—Each resistance thermometer or thermocouple sensor shall be placed in an individual stainless steel tube and packed with fine aluminum oxide powder. The stainless steel tube shall be immersed in the temperature bath fluid to a depth such that further immersion does not produce a change in the equivalent indicated temperature of more than twice the temperature bath fluid gradient.

(4) Unless otherwise specified, the test shall be performed with a sensor input current of 1 mA.

S43.5 General Examination:

S43.5.1 Visual Examination—Resistance thermometers and thermocouple sensors shall be given a thorough examination to determine that they conform to this specification and applicable drawings with respect to material, finish, workmanship, construction, assembly, dimensions, weight, marking of identification, and information plates. This examination shall be limited to those examinations that may be performed without disassembling the resistance thermometers and thermocouple sensors in such a manner that their performance, durability, or appearance will be affected.

S43.5.2 Radiographic Examination (TW and BB Configuration)—When required, the radiographic examination shall ensure that the resistance thermometer element, the thermocouple sensor’s measuring junction, and the connecting wires meet the requirements of S38.2.

S43.5.3 Sheath Straightness (TW Configuration)—A plain ring gauge having a 6.53 cm ± 2.54 µm (0.2570 ± 0.0001 in.) diameter and a length which is at least the thermowell insertion length shall be used to verify the sheath straightness. The sheath shall pass through the plain ring gauge until it hits the first spring stop.

S44. Certification

S44.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data remain on file for three years at the manufacturer’s facility for review by purchaser upon request.

S45. Product Marking

S45.1 Product marking requirements shall be specified in the acquisition requirements.

S45.2 Identification Plate—The identification plate shall include at a minimum the following:

(1) Nomenclature,
(2) Contractor’s part number,
(3) National Stock Number (NSN),
(4) Contract number,
(5) Detailed specification number,
(6) Contractor’s name or CAGE code, and
(7) Temperature range.

S45.3 Sheath (TW and BB Configurations)—Each sheath shall be clearly and permanently marked, that is, engraved or electronically etched with the Commercial and Government Entity (CAGE) number, the classification variables as specified in B4, and a model number.

S45.4 Metallic Tag (EM Configuration)—A metallic tag shall be placed at the end of the connecting wires opposite the sheath and shall be clearly and permanently marked with the same information as required in S45.3. The following notice shall be placed on the opposite side of the tag:

NOTICE

Reattach this tag to the connecting wires after bearing installation and keep affixed to the connecting wires when the bearing is placed in service.

S45.5 Connecting Metal Link (TW Configuration)—The connecting metal links on the connection head terminal board for resistance thermometers shall be marked “R” and “W,” respectively, for the red and white insulated connecting wires. The connecting metal links on the connection head terminal board for thermocouple sensors shall be marked “Y (+)” and “R(-)” for the yellow and red insulated connecting wires.

S45.6 Connector Receptacle (BB Configuration)—The connector receptacle pins for resistance thermometers with platinum elements shall be marked “B” for the single connecting wire on one side of the resistance thermometer element and shall be marked “A” and “C” for the two connecting wires on either side of the resistance thermometer element. The connector receptacle pins for resistance thermometers with nickel elements shall be marked “A” and “B” for the two connecting wires on each side of the resistance thermometer element. The connector receptacle pins for thermocouple sensors shall be marked “(+)” and “(-)” for the positive and negative connecting wire respectively.

S45.7 Connecting Head Plate (TW Configuration)—An identification plate shall be affixed to the connecting head cap.

S46. Packaging and Package Marking

S46.1 Packaging and package marking shall be in accordance with Section 15.

S47. Quality Assurance Provisions

S47.1 Warranty—Special warranty requirements shall be specified in the acquisition requirements. Otherwise, the standard commercial warranty applies.
The following appendix to supplementary requirements established for U.S. Naval shipboard application shall apply when specified in the contract or purchase order. When there is conflict between the standard (ASTM F 2362) and this supplement’s appendix, the requirements of this supplement’s appendix shall take precedence for equipment acquired by this supplement’s appendix. This document supercedes MIL-S-24795, Sensors, Temperature, Fiber Optic (Naval Shipboard Use), for new ship construction.

S48. Scope

S48.1 This supplement covers single-channel, fiber optic temperature sensors designed to meet the requirements for use onboard naval ships.

S48.2 This specification covers the requirements for single-channel, fiber optic temperature sensors for general applications. The fiber optic temperature sensor usually consists of the sensor head that is in contact with the measured media, embedded in babbitt material, or housed inside a thermowell. Using connectorized fiber optic cable, a separate optoelectronics module translates the optical input to a continuous linear proportional analog electrical signal or other output signal such as optical or digital.

S48.3 The U.S. Government preferred system of measurement is the metric SI system. However, since this item was originally designed using inch-pound units of measurement, in the event of conflict between the metric and inch-pound units, the inch-pound units shall take precedence.

S50. Terminology

S50.1 Terminology Defined—Terms marked with (ANSI/ISA S37.1) are taken directly from ANSI/ISA S37.1 (R-1982) and are included for the convenience of the reader.

S50.2 Definitions—Terminology consistent with ANSI/ISA S37.1 shall apply, except as modified by the definitions listed as follows:

S50.2.1 ambient conditions—conditions such as pressure and temperature of the medium surrounding the case of a sensor (ANSI/ISA S37.1).

S50.2.2 babbitt—metal material commonly used in bearing and temperature sensor installations which wears in with equipment operation providing a wear surface and heat transfer
medium. Babbit is softer than the base or substrate material and softer than mating component materials, where applicable.

S50.2.3 bare-bulb type sensor head—sensor head design where the sensing element is exposed directly to the process fluid being measured.

S50.2.4 calibration—test during which known values of measurands are applied to the sensor and corresponding output readings are recorded under specific conditions (ANSI/ISA S37.1).

S50.2.5 embedded type sensor head—sensor head design which is embedded in babbitt material which isolates the sensor element from the process fluid and, in some instances, moving or rotating components, but still allows the temperature to be monitored.

S50.2.6 environmental conditions—specified external conditions such as shock, vibration and temperature to which a sensor may be exposed during shipping, handling, and operation (ANSI/ISA S37.1).

S50.2.7 error—algebraic difference between the indicated value and the true value of the measurand (ANSI/ISA S37.1).

S50.2.8 fiber optic temperature sensor—a device that converts sensed temperature to a proportional output signal via changes in fiber optic properties. The fiber optic temperature sensor normally consists of a sensor head, opto-electronics module, and connectorized fiber optic cable.

S50.2.9 hysteresis—the difference in sensor output when compared at the same temperature under the same environmental conditions with one data point taken with ascending temperature and another with descending temperature.

S50.2.10 operating environmental conditions—environmental conditions during exposure to which a sensor must perform in some specified manner (ANSI/ISA S37.1).

S50.2.11 optical—involving the use of light sensitive devices to acquire information.

S50.2.12 optical fiber—a very thin filament or fiber, made of dielectric materials, that is enclosed by material of lower index of refraction and transmits light throughout its length by internal reflections.

S50.2.13 opto-electronics module—a component of the fiber optic temperature sensor that contains the optical source and detector, and signal conditioner devices necessary to convert the sensed temperature to a specified output signal.

S50.2.14 output—electrical or numerical quantity, produced by a sensor or measurement system, that is a function of the applied measurand.

S50.2.15 range—measurand values over which a sensor is intended to measure, specified by their upper and lower limits (ANSI/ISA S37.1).

S50.2.16 repeatability—ability of a sensor to reproduce output readings when the same measurand value is applied to it consecutively, under the same conditions, and in the same direction (ANSI/ISA S37.1).

S50.2.17 response time—the time required for a sensor to indicate a step change in temperature or the time difference between an actual step change in temperature applied and the corresponding change in sensor output.

S50.2.18 sensitivity factor—the ratio of fiber optic temperature sensor output signal percentage change of span to applied bath temperature percentage change of span.

S50.2.19 sensor element—that part of the sensor that responds directly to the measurand (ANSI/ISA S37.1).

S50.2.20 sensor head—the transduction element of a fiber optic temperature sensor that detects temperature via changes in optical properties.

S50.2.21 sheath—the protective covering of a sensor element.

S50.2.22 SI (Le Systeme International d’Unites) units—units of measurement recognized by the CIPM (Comite’ International des Poids et Mesures).

S50.2.23 signal conditioner—an electronic device that makes the output signal from a transduction element compatible with a readout system.

S50.2.24 span—the algebraic difference between the limits of the measurement range.

S50.2.25 static error band—the maximum deviation from a straight line drawn through the coordinates of the lower range limit at specified sensor output and the upper range limit at specified output expressed in percentage of sensor span.

S50.2.26 thermowell—a pressure tight receptacle adapted to receive a temperature sensing element and provided with the external threads or other means for pressure tight attachment to the vessel.

S50.2.27 thermowell type sensor head—sensor head design which is intended to be used with a thermowell which isolates the sensor element from the process fluid being measured while maintaining the pressure boundary.

S50.2.28 warm-up time—the time required for a sensor to operate within specified requirements after being re-energized from a cold (ambient) state.

S51. Classification

S51.1 Design Type—The fiber optic temperature sensor shall consist of a series of designations which shall be assigned and listed in the format below.

Example: ASTM F2362S48-T4-DC-A-VC-2

S51.2 Type—The sensor head type shall be designated as follows:

T1—Thermowell (see Fig. S8 and Fig. S9)
T2—Thermowell (see Fig. S8 and Fig. S9)
T3—Thermowell (see Fig. S8 and Fig. S9)
T4—Thermowell (see Fig. S8 and Fig. S9)
EM—Embedded (Bearing Applications, see Fig. S8 and Fig. S10)
B1—Bare-bulb (see Fig. S11)
B2—Bare-bulb (see Fig. S11)

S51.3 Input Power—The input power required to operate the opto-electronics module shall be designated as follows:

DC—28 V direct current (Vdc)
AC—115 V alternating current (Vac)

S51.4 Opto-electronics Module—The opto-electronics module type shall be designated as follows:
A—Junction box enclosure
B—Control console module
C—Monitoring and alarm panel module

S51.5 Signal Output—The signal output shall be designated as follows:

E—Digital electrical output
S51.6 Range—The sensor measurement range shall be designated as follows:
1: -40 to 150°C (-40 to 302°F)
2: 0 to 300°C (32 to 572°F)
3: -40 to 300°C (-40 to 572°F)

S52. Ordering Information
S52.1 The purchaser shall provide the manufacturer with all of the pertinent application data shown in accordance with S52.2. If special application operating conditions exist that are not shown in the acquisition requirements, they shall also be described.

S52.1 Acquisition Requirements—Acquisition documents should specify the following:
1. Title, number, and date of this specification,
2. Quantity of fiber optic temperature sensors required,
3. Fiber optic temperature sensor classification required:
   (a) Sensor type,
   (b) Input power,
   (c) Opto-electronics module,
   (d) Signal output, and
   (e) Range.
4. When qualification inspection is required,
5. Final disposition of qualification test samples,
6. National Stock Number (NSN) if available,
(7) Unique product marking requirements, and
(8) Unique preservation, packaging and marking require-ments.

S53. Materials and Manufacture

S53.1 Sensing Elements—The materials for all wetted parts shall be selected for long term compatibility with the process medium. For example, corrosion resistant steel or monel are compatible with long term exposure to seawater.

S53.2 Metals—Unless otherwise specified herein, all metals in the construction of the sensor shall be corrosion resistant. Dissimilar metals shall not be used in close physical contact with each other unless suitably finished to prevent electrolytic corrosion. Materials used to fabricate the sensor head for the embedded configuration shall have a Brinell hardness less than 170 to ensure that shaft scoring does not occur.

S53.3 Flammable Materials—Materials used in the construction of the sensor shall, in the end configuration, be noncombustible or fire retardant in the most hazardous conditions of atmosphere, pressure and temperature to be expected in the application. Fire retardant additives may be used provided they do not adversely affect the specified performance requirements of the basic materials. Fire retardance shall not be achieved by use of nonpermanent additives to the basic material.

S53.4 Fungus Resistant Materials—Materials used in the construction of the sensor shall be fungus inert materials.

S53.5 Solvents, Adhesives, and Cleaning Agents—If any chemicals or cements are used in bonding of internal components, no degradation shall result during in-service use.

S53.6 Refractive Index Matching Gels, Fluids, or Compounds—Refractive index matching gels, fluids, or compounds shall be in accordance with MIL-M-24794 and shall not produce toxic, corrosive, or explosive byproducts. The material is subject to a toxicological data and formulations review and inspection, for safety of material, by the purchaser. The index matching material shall be either silicone or aliphatic hydrocarbon material and shall be clear and transparent. The index matching material shall have an index of refraction of 1.46 ± 0.01 as tested in accordance with Test Method D 542 when exposed to operating temperature extremes between -28°C and +85°C (-18.4 and 185°F). The index matching material shall not flow at elevated temperatures. The index matching material shall remain clear and transparent when tested for water absorption in accordance with Test Method D 570. The index matching material shall have a shelf life not less than 36 months at 25 ± 5°C (77 ± 9°F). The 36 month period commences on the date of adhesive manufacture.

S54. Physical Properties

Fiber optic temperature sensors convert the thermal energy surrounding the sensor head to a continuous linear analog dc signal or specified digital output throughout a specified measurement range. The fiber optic temperature sensor shall consist of a sensor head, opto-electronics module, and fiber optic cable interconnect. All parts of the fiber optic temperature sensor shall be interchangeable with the appropriate replace-ment parts with respect to form, fit, and function, and maintain the specified accuracy requirements.

S54.1 Sensor Head—The sensor head shall detect the surrounding temperature. The sensor head shall be passive in nature by detection of temperature through a change in optical properties. Neither electrical nor electronic components shall be used in the construction of the sensor head.

S54.1.1 Thermowell Type—The sensor head shall be constructed in accordance with Fig. S8 and Fig. S9. The sensor head dimensions shall be in accordance with Fig. S8 and Fig. S9. The sensor head shall have a weight not greater than 1 kg.

S54.1.2 Embedded Type—The sensor head shall be constructed in accordance with the dimensions shown in Fig. S10. The babbitt topping material shall be in accordance with Specification B 23 (grade 2).

S54.1.3 Bare-bulb Type—The bare-bulb type sensor head dimensions shall be in accordance with Fig. S11. The sensor head shall have a weight not greater than 1 kg (2.2 lb). The sensor sheath shall be designed to withstand application conditions of 37.66 Mpa (5500 pounds per square inch), 210°C (410°F), and an open air flow velocity of 12.2 m (40 ft) per second. Conformance shall be proven by using a mathematical model approved by the Power Test Code Thermometer Wells, ASME PTC 19.3:1.

S54.2 Opto-electronics Module:

S54.2.1 Junction Box Enclosure (Type A)—The opto-electronics shall be housed in a junction box. MIL-E-24142 and MIL-E-24142/3 may be used as guidance for the junction box. At a minimum, the dimensions, mounting requirements, and cable entrance shall be in accordance with MIL-E-24142 and MIL-E-24142/3. The opto-electronics module shall have a weight no greater than 4.5 kg (9.92 lb).

S54.2.2 Control Console Module (Type B)—The opto-electronics shall be packaged in a circuit card which is a modular subassembly of a control console. Design and test requirements for the opto-electronics module shall be as specified in the acquisition requirements.

S54.2.3 Monitoring and Alarm Panel Module (Type C)—The opto-electronics shall be packaged in a module which is a subassembly of a bulkhead mounted temperature monitoring and alarm panel. Design and test requirements for the opto-electronics module shall be as specified in the acquisition requirements.

S54.3 Fiber Optic Cable:

S54.3.1 Thermowell and Bare-bulb Sensor Types—The cable used to interface the sensor head and the opto-electronics module shall have an outer diameter of a four fiber cable in accordance with MIL-C 85045. In the cable, there shall be no less than two times the number of fibers required for operation of the sensor. The cable shall be supplied with a stuffing tube (size 2, military part number M19622/1-002 in accordance with MIL-S-19662/1), and packing assembly (military part number M19622-17-0001 in accordance with MIL-S-19662/17) in accordance with MIL-S-19622, and an o-ring installed on each end of the cable to accomplish watertight penetration into the sensor head and opto-electronic module. The o-rings used shall be petroleum hydraulic fluid resistant and shall be rated to perform in high temperature applications 135°C
Embedded Sensor Type—The cable used to interface the sensor head and a local interconnection box shall be in accordance with MIL-C-85045. The cable length shall be as specified in the acquisition requirements.

Optical Fiber—Optical fiber used to transmit light between the opto-electronics module and the sensor head shall be in accordance with MIL-F-49291.

Fiber Optic Connectors, Receptacles, and Bulkhead Adapters—All fiber optic connectors, receptacles, and bulkhead adapters shall be in accordance with MIL-C-83522 and MIL-C-83522/16,17, and 18, respectively. The fiber optic cable for the thermowell sensor type shall be terminated at both ends with connectors. The fiber optic cable for the embedded and bare-bulb sensor configurations shall be terminated with a connector at the end which interfaces with the opto-electronic module. MIL-STD-2042 method 5B1 may be used as guidance. The connectors and receptacles shall be mounted inside the sensor head (thermowell sensor type only) and the opto-electronic module.

Electrical Input Power—Nominal steady-state power supply requirements for ac shall be 115 ± 8 Vac, 60 Hertz, single phase. Nominal steady-state power supply requirements for dc shall be 28 ± 4.5 Vdc. The sensor shall operate with power supply variations as specified (see S58.8.1 through S58.8.6).

Output Signal:

Current Output—When a current output is required, the output signal shall be directly proportional to the temperature being measured. The 4 mA output shall correspond to the lower temperature range value and the 20 mA output shall correspond to the upper temperature range value. The current output shall remain accurate regardless of external load resistance variations over a range of 0 to 250 Ω.

Voltage Output—When a voltage output is required, the output signal shall be directly proportional to the temperature being measured. The lower dc voltage output shall correspond to the lower temperature range value and the higher dc voltage output shall correspond to the upper temperature range value. The voltage output shall remain accurate regardless of external load resistance greater than 1000 Ω. Typical voltage outputs include 0-5 Vdc, 0-10 Vdc and 0-12 Vdc.

Digital Optical Output—When a digital optical output is required, the output signal specifications shall be specified in the acquisition requirements.

Digital Electrical Output—When a digital electrical output is required, the electrical characteristics shall be those specified in EIA standards RS-422 for balanced voltage digital interface circuitry or as specified in the acquisition requirements. The data format shall also be specified in the acquisition requirements.

Electrical Connectors—A single electrical receptacle in accordance with MIL-C-5015 shall be used to interface with the input power and linear output signal to the opto-electronics module. When a digital optical or digital electrical output signal is specified, connectors shall be as specified in the acquisition requirements. The appropriate connector assembly and pin designations for each of the possible fiber optic temperature configurations shall be as specified as follows:

DC Input Power—The receptacle mounted to the opto-electronics module shall be classification MS3452W14S-5PX in accordance with MS3452. Receptacle pin “A” shall be positive 28 Vdc input power, pin “B” shall be negative 28 Vdc input power, pin “C” shall be the case ground, pin “D” shall be positive mA or high Vdc output signal, and pin “E” shall be the negative mA or low Vdc output signal. The mating plug supplied with the fiber optic temperature sensor shall be classification MS3456W14S-5SX in accordance with MS3456.

AC Input Power—The receptacle mounted to the opto-electronics module shall be classification MS3452W14S-5PX in accordance with MS3452. Receptacle pin “A” shall be positive 115 Vac input power, pin “B” shall be input power return, pin “C” shall be the case ground, pin “D” shall be positive mA or high Vdc output signal, and pin “E” shall be the negative mA or low Vdc output signal. The mating plug supplied with the fiber optic temperature sensor shall be classification MS3456W14S-5SX in accordance with MS3456.

Adjustments—A means may be provided for adjusting the output signal of the opto-electronics module for calibration purposes. If provided, the adjustments shall be situated in the opto-electronics module so that calibrations can be performed with the fiber optic temperature sensor energized.

Fuses—The opto-electronics module shall not be fused.

Performance Requirements

Accuracy—The fiber optic temperature sensor output signal accuracy shall be within ± 1 % of span (see S58.1).

Repeatability—The fiber optic temperature sensor output signal repeatability at each temperature point shall not change in value more than 0.5 % of span (see S58.2).

Reference Measurement—The fiber optic temperature sensor output signal accuracy shall be within ± 1 % of span (see S58.3).

Sensitivity Factor—The ratio of the fiber optic temperature sensor output signal percentage change of span to applied bath temperature percentage change of span shall not be less than 0.75 nor greater than 1.25 (see S58.4).

Response Time—Response time of the fiber optic temperature sensor output signal accuracy shall not be greater than 8 s for the thermowell sensor type, not greater than 5 s for the embedded sensor type, and not greater than 15 s for the bare-bulb sensor type (see S58.5).

Warm-up Time—The fiber optic temperature sensor output signal accuracy at the bath temperature shall be within ± 1 % of span within 1 min after the sensor is energized (see S58.6).

Steady-state Supply Voltage and Frequency (AC) or Supply Voltage (DC)—The fiber optic temperature sensor output signal shall be within ± 1 % of span throughout the limits of supply voltage and frequency (see S58.7).
S55.8 Transient Voltage and Frequency (AC) or Voltage (DC)—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span when subjected to transient voltage and frequency (see S58.8).

S55.9 Insulation Resistance—The insulation resistance of the fiber optic temperature sensor between circuits and between circuits and ground shall not be less than 10 megohms (see S58.9).

S55.10 Power Interruption—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span during short duration power interruptions (see S58.10).

S55.11 Short Circuit—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span after short circuit of the output signal lines (see S58.11).

S55.12 Line Voltage Reversal (DC)—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span after reversal of the input dc power lines (see S58.12).

S55.13 Temperature—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span over the ambient temperature range of 0 to 65°C (32 to 149°F) (see S58.13).

S55.14 Enclosure—The fiber optic temperature sensor output signal accuracy shall be within ±1 % of span after exposure to a coarse stream of water (see S58.14).

S55.15 Salt Spray—No corrosion or other damage shall be evident when exposed to salt spray and the fiber optic temperature sensor output signal accuracy shall be within ±1 % of span (see S58.15).

S55.16 Over-temperature—The sensor head shall show no evidence of physical damage when exposed to the limits of over-temperature and the reference measurement results shall conform to S55.3 (see S58.16).

S55.17 Accelerated Life—The sensor head shall show no evidence of physical damage when exposed to operating conditions which simulate accelerated life and the reference measurement results shall conform to S55.3 (see S58.17).

S55.18 Vibration—The fiber optic temperature sensor shall operate without interruption and show no evidence of physical damage when exposed to vibration in accordance with MIL-STD-167-1. The reference measurement results shall conform to S55.3 (see S58.18).

S55.19 Shock—The fiber optic temperature sensor shall operate without interruption and show no evidence of physical damage when exposed to shock in accordance with MIL-S-901. The reference measurement results shall conform to S55.3 (see S58.19).

S55.20 Electromagnetic Interference (EMI) Emission and Susceptibility—The fiber optic temperature sensor shall be in accordance with the requirements of MIL-STD-461 revision E, or later: CE101 (Submarine application only), CE102, CS101, CS114, CS116, RE101, RE102, RS101, and RS103 (see S58.20).

S55.21 Pressure—The fiber optic temperature sensor shall operate without interruption when exposed to a babbitt surface pressure of 12.4 MPa (1800 psi). The reference measurement shall conform to S55.3 (see S58.21).

S56. Workmanship, Finish, and Appearance

S56.1 Cleaning and Surface Finishes—Surfaces of castings, forgings, molded parts, stampings, machined and welded parts shall be free of defects such as cracks, porosity, undercuts, voids and gaps as well as sand, dirt, fins, sharp edges, scale, flux, and other harmful or extraneous materials. External surfaces shall be smooth and edges shall be either rounded or beveled. There shall be no burn-through. There shall be no warpage or dimensional change due to heat from welding operation. There shall be no damage to adjacent parts resulting from welding.

S57. Number of Tests and Retests

S57.1 The number of tests and retests, if any, shall be specified in the acquisition requirements.

S58. Test Methods

S58.1 Accuracy—The sensitive portion of the sensor head shall be immersed in a temperature bath and the fiber optic temperature sensor output signal shall be measured at 5, 25, 50, 75 and 95 % of the fiber optic temperature sensor span. Accuracy shall conform to S55.1. The fiber optic temperature sensor output signal shall conform to S55.2.

S58.2 Repeatability—The procedure specified in S58.1 shall be repeated three successive times while maintaining temperature bath conditions. The fiber optic temperature sensor head shall be removed from the bath for not less than 2 min and re-immersed at a repeatable depth for consecutive measurements at each of the five temperature points. The fiber optic temperature sensor output signal shall conform to S55.2.

S58.3 Reference Measurement—The sensitive portion of the sensor head shall be immersed in a temperature bath and the fiber optic temperature sensor output signal shall be measured at 5, 50, and 95 % of the fiber optic temperature sensor span. System accuracy shall conform to S55.1.

S58.4 Sensitivity Factor—The sensitivity factor shall be determined using the following procedure. Immerse the sensitive portion of the sensor head in a temperature bath and allow ample time to stabilize at a temperature of 80 ± 5 °C of span. Measure both the bath temperature and the fiber optic temperature sensor output signal. Increase the bath temperature by an amount not greater than 1 % of the fiber optic temperature sensor span. Measure both the new bath temperature and the fiber optic temperature sensor output signal. Calculate the change in both bath temperature and fiber optic temperature sensor output signal as a percentage of the fiber optic temperature sensor span. Determine the ratio of the output signal percentage change to applied bath temperature percentage change in terms of fiber optic temperature sensor span. Repeat this procedure for a bath temperature decrease not greater than 1 % of span. Performance shall conform to S55.4.

S58.5 Response Time—The response of the fiber optic temperature sensor shall be determined using the following procedure:

1. Bath medium: water
2. Origin bath temperature: 10°C (50°F)
3. Destination bath temperature: 82°C (180°F)
4. Initial temperature (T1): 26°C (79°F)
5. Final temperature (T2): 62°C (144°F)
The response time shall be determined as the time required for the fiber optic temperature sensor output signal to track from T1 to T2 after the sensor head in transferred from the origin bath to the destination bath. The response time of the fiber optic temperature sensor shall be the average of not less than six readings taken during not less than six consecutive trials. Performance shall conform to S55.5.

S58.6 Warm-up Time—Warm-up time shall be determined using the following procedure. Allow the sensitive portion of the sensor head to stabilize at a bath temperature of 80 ± 5 % of the fiber optic temperature sensor span. De-energize the fiber optic temperature sensor for no less than 2 h. Energize the fiber optic temperature sensor and monitor the output signal as necessary to ensure conformance to S55.6.

S58.7 Steady-state Supply Voltage and Frequency (AC) or Supply Voltage (DC)—The fiber optic temperature sensor output signal shall be monitored for no less than 15 min at normal, maximum, and minimum steady-state voltage and frequency conditions as specified in S58.8. The fiber optic temperature sensor shall be subjected to each of the applicable power supply conditions for no less than 1 h at ambient temperatures of 0, 25, and 65°C (32, 77, and 149°F). The fiber optic temperature sensor signal output shall be measured after not less than 1 h at each test condition. This test may be performed in conjunction with the temperature test (see S58.13). Performance shall conform to S55.7.

S58.8 Transient Supply Voltage and Frequency (AC) or Supply Voltage (DC)—The fiber optic temperature sensor output signal shall be monitored at ambient temperature during each test procedure defined below. Performance shall conform to S55.8.

S58.8.1 Transient Voltage Upper Limit (AC)—With the fiber optic temperature sensor operating at a voltage of 123 Vac, the voltage shall be increased to 138 Vac, and then decreased back to the steady-state voltage of 123 Vac in a 2 s period.

S58.8.2 Transient Voltage Lower Limit (AC)—With the fiber optic temperature sensor operating at a voltage of 107 Vac, the voltage shall be decreased to 92 Vac, and then increased back to the steady-state voltage of 107 Vac in a 2 s period.

S58.8.3 Transient Frequency Upper Limit (AC)—With the fiber optic temperature sensor operating at a frequency of 62 Hz, the frequency shall be increased to 63.5 Hz, and then decreased back to the steady-state frequency of 62 Hz in a 2 s period.

S58.8.4 Transient frequency lower limit (AC)—With the fiber optic temperature sensor operating at a frequency of 58 Hz, the frequency shall be decreased to 56.5 Hz, and then increased back to the steady-state frequency of 58 Hz in a 2 s period.

S58.8.5 Transient Voltage Upper Limit (DC)—With the fiber optic temperature sensor operating at a voltage of 32.5 Vdc, the voltage shall be increased to 34.5 Vdc, and then decreased back to the steady-state voltage of 32.5 Vdc in a 2 s period.

S58.8.6 Transient Voltage Lower Limit (DC)—With the fiber optic temperature sensor operating at a voltage of 23.5 Vdc, the voltage shall be decreased to 21.5 Vdc, and then increased back to the steady-state voltage of 23.5 Vdc in a 2 s period.

S58.9 Insulation Resistance—The insulation resistance of the opto-electronics module circuits shall be determined by applying 50 Vdc between electrical input and output circuits and between these circuits and the ground. The insulation resistance measurement shall be made immediately after a 2 min period of uninterrupted test voltage application. If the indication of insulation resistance meets the specified limit (see S55.9) and is steady or increasing, the test may be terminated before the end of the 2 min period. Performance shall conform to S55.9.

S58.10 Power Interruption—The fiber optic temperature sensor shall be energized and the output signal monitored at ambient temperature throughout the test. The external power supply shall be suddenly interrupted, and after an interval not less than 4 s, the power supply shall be reapplied to the fiber optic temperature sensor. Performance shall conform to S55.10.

S58.11 Short Circuit—The fiber optic temperature sensor shall be de-energized and the positive and negative electrical output terminals of opto-electronics module shall be connected directly together, with no load resistance. The fiber optic temperature sensor shall be energized for 5 min, then deenergized and the short circuit removed. The fiber optic temperature sensor shall be energized and the output signal measured at ambient temperature. Performance shall conform to S55.11.

S58.12 Line Voltage Reversal (DC)—The positive 28 Vdc power input shall be applied to connector pin “B” and the reference shall be applied to connector pin “A.” The power supply shall be energized for a period of no less than 10 min. The fiber optic temperature sensor output signal shall be measured at ambient temperature. The fiber optic temperature sensor shall be de-energized and the power supply connections shall be reversed to normal polarity. The fiber optic temperature sensor shall then be energized for no less than 5 min before the output signal is measured at ambient temperature. Performance shall conform to S55.12.

S58.13 Temperature—The fiber optic temperature sensor shall be positioned in an environmental chamber in an energized state, and shall be subjected to the following conditions consecutively:

1. Hold temperature at 0 ± 2°C (32 ± 3.6°F) for 24 h.
2. Increase temperature in steps of 10°C (18°F) at 30 min per step until 65 ± 2°C (149 ± 3.6°F) is achieved.
3. Hold temperature at 65 ± 2°C (149 ± 3.6°F) for 24 h, and
4. Reduce temperature in steps of 10°C (18°F) at 30 min per step until 25 ± 2°C (77 ± 3.6°F) is achieved.

Measure the fiber optic temperature sensor output signal at one point during the last hour of operation at each temperature.
plateau, that is 0, 25, and 65°C (32, 77, and 149°F). Performance shall conform to S55.13.

S58.14 Enclosure—The fiber optic temperature sensor head and no less than a two meter section of the attached cable interconnect shall be mounted to a surface which extends no less than 1 m (3.28 ft) beyond the sensor head on all sides so that splashing shall be produced by directing the water stream on that surface. The fiber optic temperature sensor shall be de-energized throughout the test. The water stream shall be a coarse spray with a flow rate of no less than 57 L (15 gal) per minute. The nozzle to the enclosure under test shall be approximately 2 m (6.56 ft). The distance from the nozzle to the enclosure under test shall be no less than 57 L (15 gal) per second and a head pressure of no less than 3 m (9.84 ft). A head pressure of 3 m (9.84 ft) is defined as sufficient water pressure so that if directed straight up, the stream of water shall rise to a height of no less than 3 m (9.84 ft). The distance from the nozzle to the enclosure under test shall be approximately 2 m (6.56 ft). The time of the test shall be no less than 5 min with approximately equal portions of time for spray on each surface, including joints of the enclosure and at the surface at which the enclosed equipment is mounted. The fiber optic temperature sensor components shall be examined at the immediate conclusion of the test for moisture penetration. The fiber optic temperature sensor shall be energized and the output signal monitored at ambient temperature at the conclusion the test. Performance shall conform to S55.14.

S58.15 Salt Spray (Fog)—The fiber optic temperature sensor head and no less than a 1 m (3.28 ft) section of the attached cable interconnect shall be subjected to salt spray in accordance with Test Method B 117. This test is not applicable to the embedded sensor configuration since it will be secured in a bearing. The fiber optic temperature sensor shall be de-energized throughout the test. Duration of the test shall be no less than 5 min with approximately equal portions of time for spray on each surface, including joints of the enclosure and at the surface at which the enclosed equipment is mounted. The fiber optic temperature sensor components shall be examined at the immediate conclusion of the test for corrosion and moisture penetration. The fiber optic temperature sensor shall be energized and the output signal monitored at ambient temperature at the conclusion of the test. Performance shall conform to S55.15.

S58.16 Over-temperature—The sensitive portion of the fiber optic temperature sensor head shall be rapidly transferred from ambient conditions to a temperature bath stabilized at 125% of the fiber optic temperature sensor full scale temperature. The sensor head shall remain immersed in the bath for 15 min and then returned to ambient conditions. A reference measurement (see S55.3) shall be performed at the conclusion of the over-temperature test. Performance shall conform to S55.16.

S58.17 Accelerated Life—The sensitive portion of the sensor head shall be thermally cycled between the following temperatures for 1500 cycles at a rate not greater than 2 cycles per minute:

<table>
<thead>
<tr>
<th>Sensor Range</th>
<th>Temperature Cycling Points</th>
</tr>
</thead>
<tbody>
<tr>
<td>-40 to 150°C (-40 to 302°F)</td>
<td>Ambient to -30 ± 2°C (-22 ± 3.6°F)</td>
</tr>
<tr>
<td>0 to 300°C (32 to 572°F)</td>
<td>Ambient to 285 ± 2°C (545 ± 3.6°F)</td>
</tr>
</tbody>
</table>

The fiber optic temperature sensor output signal shall be monitored during thermal cycling and observed for operation without interruption. A reference measurement (see S55.3) shall be performed at the conclusion of the thermal cycling test. Performance shall conform to S55.17.

S58.18 Vibration—The fiber optic temperature sensor shall be tested in accordance with MIL-STD-167-1, type 1. Test fixtures shall be designed to simulate the shipboard installation of the sensor type. The fiber optic temperature sensor output signal shall be monitored throughout the test and visually examined for operation without interruption, especially at resonant frequencies. The fiber optic temperature sensor shall be visually examined for physical damage during and at the conclusion of the test. A reference measurement in accordance with S55.3 shall be performed at the conclusion of the test. Performance shall conform to S55.18.

S58.19 Shock—The fiber optic temperature sensor shall be fully assembled, energized, and tested in accordance with grade A, class 1, type A of MIL-S-901. Test fixtures shall be designed to simulate the shipboard installation of the sensor type. The fiber optic temperature sensor shall be visually examined for physical damage after each hammer blow and at the conclusion of the test. A reference measurement in accordance with S55.3 shall be performed at the conclusion of the test. Performance shall conform to S55.19.

S58.20 EMI Emission and Susceptibility—EMI tests shall be in accordance with the test methods specified in MIL-STD-461 revision E, or later. Performance shall conform to S55.20.

S58.21 Pressure—A reference measurement (see S55.3) shall be performed prior to the test to ensure the sensor head is not defective. The sensor head under test shall be installed in a fixture made from mild steel. The critical dimensions to which the fixture shall conform are shown on Fig. S12. The 19.05 mm (0.75 in.) diameter counterbore shall contain Specification...
B 23 (grade 2) babbitt flush with the test fixture surface. The babbitt surface shall then be exposed to a gauge pressure of 12.411 ± 0.07 MPa (1800 ± 10 pounds per square inch) for not less than 5 min. The fiber optic temperature sensor output signal shall be monitored during the test and examined for operation without interruption. The babbitt shall be removed from the 19.05 mm (0.75 in.) counterbore and a reference measurement (see S55.3) shall be performed. Performance shall conform to S55.21.

S59. Inspection

S59.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

(a) Qualification testing, and
(b) Quality conformance testing.

S59.2 Qualification Testing—Qualification testing shall be performed prior to production. Qualification testing shall be performed on samples which have been produced with equipment and procedures normally used in production. Qualification testing shall consist of the examinations and tests in the order specified in Table S21. Failure of any sensor to meet the requirements of this specification shall be cause for rejection.

S59.2.1 Sample Size—Two fiber optic temperature sensors of each lot shall be subjected to the qualification inspection. An inspection lot shall consist of all sensors of the same classification (see C4), produced under essentially the same conditions, in the same facility from the same materials and offered for delivery at the same time. One sample shall be subjected to the tests of Group I. The two samples shall be supplied with the length of cable required for the intended application, but shall not be less than 30.5 m (100 ft). The Group II test requires an additional embedded sensor due to the destructive nature of the test and shall only be accomplished for acquisitions for embedded designs.

S59.3 Quality Conformance Testing—Each sensor in each lot offered for delivery shall be subjected to the inspection listed in Table S22 and shall be conducted in the order listed.

S60. Certification

S60.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test result shall be furnished. It is recommended that all test data remain on file for three years at the manufacturer’s facility for review by purchaser upon request.

S61. Product Marking

S61.1 Opto-electronics Module—Each opto-electronics module shall be permanently and legibly marked in accordance with the acquisition requirements. The following minimum information shall be provided:

(1) Nomenclature,
(2) Design classification,
(3) National Stock Number (NSN) if available,
(4) Manufacturer’s name and model number,
(5) Temperature range,
(6) Contract number, and
(7) A unique serial number from the manufacturer.
S61.2 Sensor Head—Each sensor head shall be permanently
and legibly marked in accordance with the acquisition require-
ments. The following minimum information shall be provided:
(1) Nomenclature,
(2) Design classification,
(3) National Stock Number (NSN) if available,
(4) Manufacturer’s name and model number, and
(5) A unique serial number from the manufacturer.
S61.2.1 Embedded Sensor Head—In addition to the above,
the embedded sensor type shall use a removable metal tag
which attaches to the cable interface for identification marking.
The following notice shall be marked on the opposite side of
the tag:

NOTICE
Reattach this tag to the cable interface after bearing
insulation and keep affixed after the bearing is placed
in service.

S61.3 Warning Labels—A visible label shall be affixed to
the outside of the opto-electronics module cover and shall
contain the following:

WARNING
UNTERMINATED OPTICAL CONNECTORS MAY
EMIT LASER RADIATION. DO NOT VIEW BEAM
WITH OPTICAL INSTRUMENTS AND AVOID
DIRECT EXPOSURE TO BEAM.

A visible label shall be affixed to the sensor head and the
inside of the opto-electronics module and shall contain the
following:

WARNING
INVISIBLE LASER RADIATION. AVOID EXPOSURE
TO THE BEAM.
The labels shall be yellow lettering on a black background.

S62. Packaging and Package Marking
S62.1 Fiber optic temperature sensors shall be individually
packaged and marked in accordance with Section 15.

S63.1 Warranty—Special warranty requirements shall be
specified in the acquisition requirements. Otherwise, the stan-
dard commercial warranty applies.
