4.3 Type 3—Insulation monitor for 440-V, 3-phase or single-phase, 60-Hz, ac ungrounded systems.

4.4 Type 4—Insulation monitor for 440-V, 3-phase or single-phase, 400-Hz, ac ungrounded systems.

4.5 Type 5—Insulation monitor for up to 1000-V, 3-phase or single-phase, 50 to 400-Hz, ac ungrounded systems.

\(^1\) This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.10 on Electrical.

\(^2\) Available from Underwriters Laboratories, Inc., 333 Pfingsten Rd., Northbrook, IL 60062.
5. Ordering Information

5.1 Monitoring devices shall be ordered by specifying the following information:
   5.1.1 Nominal voltage and frequency.
   5.1.2 Response value/set point range in kilohm.
   5.1.3 Special options, that is, test buttons, ohmmeters, visual indicators, and so forth.

6. Requirements

6.1 The measuring voltage shall not increase more than 10 % when the monitor is supplied with 110 % of the input voltage.
6.2 The monitor shall be capable of both continuous and on-demand operation.
6.3 The monitor shall have provisions for an external (remote) audible or visual alarm to operate when the resistance value falls below the response value or a remote indication of the insulation value of the ac ungrounded system in kilohms, or both.
6.4 The ac internal resistance shall be at least 250-Ω/V nominal voltage. The minimum resistance shall not be less than 15 kΩ.
6.5 The dc internal resistance shall be at least 30-Ω/V nominal voltage and shall limit the measuring dc output current from exceeding 12 mA.
6.6 The monitor’s response tolerance shall not exceed ±5 % of the set point value at room temperature (25 ± 5°C (72 ± 9°F)) and rated input voltage.
6.7 When specified, insulation monitors shall be furnished with adjustable response values and designed to preclude tampering or unauthorized changes.
6.8 The insulation monitor shall reliably function in an ambient temperature range from 0 to 50°C (32 to 122°F). Storage temperatures of −20 to +60°C (−4 to 140°F) must not damage the insulation monitors.
6.9 Insulation monitors shall include a built-in test device or be equipped with connection provisions for a test device to be furnished with the equipment which can verify the monitor’s proper functioning. If the monitor is equipped with a built-in test device, the value of the test resistor shall be marked on the monitor.
6.10 Insulation monitors shall include an integral visual indicator or external connection provisions for external annunciation of the monitor’s set-point response.
6.11 If the insulation monitor includes an ohmmeter for the insulation resistance indication, the meter’s tolerance (actual rather than indicated values) shall not exceed ±5 % for:
   6.11.1 An insulation monitor with one preset response value at this value.
   6.11.2 An insulation monitor with adjustable response value at the midpoint of the adjustment range.
   6.11.3 Conditions of room temperature (as specified in 6.6) and rated input voltage.
6.12 Built-in relays for connection to external alarms shall have a switching capacity of at least 2 A at 250-V ac or 0.5 A at 120-V dc.
6.13 Between isolated, outgoing circuits and between these circuits and extraneous conductive parts, insulation monitors shall have creepage and air gap separation in accordance with UL 1053 for voltages up to 300 V. For higher nominal voltages, see IEC Report 664.

7. Product Marking

7.1 The following data shall be identified on an insulation monitor’s enclosure:
   7.1.1 Name of manufacturer.
   7.1.2 Type of monitor.
   7.1.3 Connection diagram.
   7.1.4 Nominal voltage rating.
   7.1.5 Input voltage.
   7.1.6 Nominal frequency.
   7.1.7 Response value or range.
   7.1.8 Test resistance value in accordance with 6.9.
   7.1.9 Serial number, or year of production.

8.1 The manufacturer’s equipment manual shall provide the following information in addition to that required in 7.1:
   8.1.1 Description of operation.
   8.1.2 Values for ac and dc internal resistance.
   8.1.3 Connection diagram.
   8.1.4 Nominal value of dc measuring voltage, based on possible supply voltages.
   8.1.5 Maximum dc measurement current at short-circuit conditions.
   8.1.6 Nominal contact voltage and current ratings for integral relays in accordance with 6.12.
   8.1.7 A note advising that external dc voltage applied to the monitor’s measuring terminals may falsify the indication or destroy the insulation monitor.
   8.1.8 Magnitude of external dc voltages, independent of their polarity, which may continuously be applied to the insulation monitor without damaging it.

9. Test Methods

9.1 Type Test—Perform type testing of insulation monitors to confirm that the response tolerances stipulated are not exceeded and that the requirements of Section 6 are met. A newly developed monitor shall be in complete compliance with the following:
   9.1.1 The measuring devices used for testing shall enable a slow stepless or step-by-step alteration of the simulated insulation resistance. On testing, the resistance shall be decreased slowly and the insulation monitor’s response shall be observed.
   9.1.2 Voltage measurements shall be taken to confirm that the requirements of 6.1 and 8.1.4 are met. The voltmeter’s internal resistance shall have a minimum value not less than 100 times the dc internal resistance of the measuring circuit.
   9.1.3 The ac internal resistance specified in 6.4 shall be verified with an rms milliampmeter and a power supply having

---

an output rated at nominal voltage and nominal frequency, an internal resistance of under 10 Ω, and a harmonic distortion of less than 5 %. The rms milliammeter shall be connected between the monitor’s measuring terminal(s) and output terminal of the power supply. The other output terminal of the power supply shall be connected to the monitor’s ground terminal. The monitor’s internal impedance, χ, shall be calculated as follows:

\[
χ = \frac{\text{nominal voltage}}{\text{ac rms current}}
\]

9.1.4 When insulation monitors have steplessly adjustable response values, test at least five points within the marked adjustment range in order to verify the requirements of 6.6. For this purpose, test the ranges’ starting and final points and uniformly distributed points within the range.

9.2 Production Test—The production test proves the correct quality and functioning of new monitors. Each insulation monitor shall be subjected to these tests.

9.2.1 Visually examine each monitor to verify appropriate markings as specified in Section 7.

9.2.2 Perform routine tests at room temperature (25 ± 5°C (72 ± 9°F)) with rated input voltage and by a measuring device complying with the requirements of 9.1.1.

9.2.3 When the insulation monitors have a steplessly adjustable response value, test the response at the range’s starting and final points.

9.2.4 Perform a voltage withstand test on the monitor to verify that the monitor is able to withstand an ac test voltage equal to twice the nominal voltage plus 1000 V for a period of 1 s without any breakdown or flashover. Perform the tests as follows:

9.2.4.1 Bridge all primary terminals.
9.2.4.2 Bridge all electronic terminals.
9.2.4.3 Bridge all relay contacts.
9.2.4.4 Apply the test potential as follows: (a) between bridged primary terminals and bridged electronic terminals; (b) between bridged primary terminals and bridged relay contacts; and (c) between bridged electronic terminals and bridged relay contacts.
9.2.4.5 Connect all bridged circuits together.
9.2.4.6 Apply test potential between the connected, bridged circuits and all dead metal parts that may become live (for example, enclosures).
9.2.5 Verify that the built-in test device is properly functioning.
9.2.6 If indicating instruments are built into the insulation monitor, verify that these instruments do not exceed the response tolerances specified in 6.11.

10. Keywords

10.1 active ac electrical system; electrical; electrical insulation; electrical insulation monitor; ohmic insulation faults; shipboard; ungrounded electrical systems
Standard Specification for Berths, Marine

This standard is issued under the fixed designation F 1244; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the construction of marine berths for officers, crew, and passengers.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:
   A 366/A 366M Specification for Commercial Steel (CS) Sheet, Carbon, (0.15 Maximum Percent) Cold-Rolled
   A 512 Specification for Cold-Drawn Butt weld Carbon Steel Mechanical Tubing
   F 825 Specification for Drawers, Furniture, Marine, Steel
   F 1085 Specification for Mattress and Box Springs, Berths

2.2 American Institute of Steel Construction Manual:
   AISC Wire and Sheet Metal Gages-Equivalent Thicknesses in Decimals of an Inch, U.S. Standard Gage for Uncoated, Hot and Cold Rolled Sheets

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 base— the structure on which the drawer and pan sections are supported and which serves to tie the berth to the deck.

3.1.2 berth—an item of fixed or built-in furniture for sleeping, with a base and drawer section below the mattress and box spring pan.

3.1.3 berth side rail—the berth side that runs from head to foot of berth.

3.1.4 box spring—the resilient box-type support for the mattress covered by fabric.

3.1.5 drawer section—the section of the berth below the pan section normally designed to contain drawers for stowage of life preservers and other items.

3.1.6 hand—the berth may be right hand, left hand, or finished both sides for use in the middle of the room. Right hand is defined as follows: the berth is right hand if the head of the berth is on the right hand end when the berth is viewed from the front. Left hand is opposite. See Fig. 1 and Fig. 2 and Table 1 and Table 2 for elevations of left-handed berths. A berth finished on both sides is not shown, but it is one that is accessible from either side, has the head of the berth against a bulkhead, and is not handed.

3.1.7 lee rail—a guard to inhibit a person from rolling out of bed because of ship motion. In this specification, the lee rail is a raised pine railing.

3.1.8 mattress—a fabric-covered, box-type unit containing springs and cushioning material that supports the sleeping surface.

3.1.9 pan section—the section of the berth designed to support the mattress and box spring.

4. Classification

4.1 Type I—A single berth with pipe, side lee rail with a box spring and mattress pan having inside measurements of 54 in. (1372 mm) wide by 80 1/2 in. (2045 mm) long. (See Fig. 1, Table 1, and Note 8 and Note 11 of Fig. 1.)

4.1.1 Type IA—Berths conforming generally to the Type I specifications but having special requirements as indicated in the ordering information.

4.2 Type II—A single berth with pipe, side lee rail with a box spring and mattress pan having inside measurements of 39 in. (991 mm) wide by 80 1/2 in. (2045 mm) long. (See Fig. 1, Table 1, and Note 8 and Note 11 of Fig. 1.)

4.2.1 Type IIA—Berths conforming generally to the Type II specifications but having special requirements as indicated in the ordering information.

4.3 Type III—A two-high berth with pipe, side lee rail, the same as Type II, but fitted with an additional pan and uprights to form an upper berth. (See Fig. 2, Table 2, and Note 8, Note 10, and Note 11 of Fig. 1.)

4.3.1 Type IIIA—Berths conforming generally to the Type III specifications but having special requirements as indicated in the ordering information.
5. Ordering Information

5.1 Orders for items purchased under this specification shall include the following:

5.1.1 Type of berth.
5.1.1.1 Type I, IA; II, IIA; or III, IIIA.
5.1.1.2 Hand—Right, left, or finished both sides.
5.1.2 Quantity—The quantity of right hand, left hand, or finished both sides for each type.
5.1.3 Mattress and Box Spring—Shall be furnished in accordance with Specification F 1085.

5.1.4 Paint:

5.1.4.1 Color—The purchaser shall pick from manufacturer’s samples or submit a sample chip of the color desired.
5.1.4.2 The manufacturer’s standard baked enamel will be furnished unless otherwise required and specified by the purchaser.

5.1.5 Weights—If the total weight of the berth assembly is required, it shall be requested by the purchaser.

5.1.6 Options:

5.1.6.1 If a special architectural appearance or finish is required for these berths to match other furniture in the same space, it shall be defined in the ordering documents.
5.1.6.2 The pipe lee rail at the foot of all berths shall be furnished extending above the mattress, to restrain occupants in heavy sea.
5.1.6.3 Normally, on berths installed in a corner, the head of the berth is installed against one of the bulkheads. On some smaller ships, the trim of the vessel is such that this configuration would place the foot of the berth higher than the head. In such cases, the head and foot shall be reversed, and this requirement shall be so noted in the ordering document.

6. Materials and Manufacture

6.1 For berth details, see Fig. 1 and Fig. 2 and Table 1 and Table 2.

6.2 Sheet Metal:

6.2.1 Sheet metal shall be steel in accordance with Specification A 366/A 366M.
6.2.2 Minimum steel sheet metal thicknesses shall be as follows:
6.2.2.1 Drawer section 18 USSG (0.0478 in. or 1.21 mm).
6.2.2.2 Pan section 18 USSG (0.0478 in. or 1.21 mm).
6.2.2.3 Base frame 16 USSG (0.0598 in. or 1.52 mm).

6.3 Welding:

6.3.1 Metal components shall be joined by welding.
6.3.2 Welding shall be adequate to prevent racking of berth components during handling.
6.3.3 Spotwelds shall be spaced approximately 3 to 5 in. (76 to 127 mm) on centers.
6.3.4 Spotwelds, on exposed surfaces, higher than the general surface of the adjacent metal, shall be ground flush.
6.3.5 Spotweld depressions, on exposed surfaces, shall be spot filled and sanded.
6.4 Side and end panels shall be suitably stiffened to prevent buckling or oil-canning.
6.5 Sound deadening shall be vermin proof and applied to unstiffened areas where needed, and in thickness required, to sound deaden berth.
6.6 Drawers shall be manufactured in accordance with Specification F 825. Minimum stowage capacity for each drawer shall be 1.35 ft³ (0.038 m³).
6.7 A furniture base shall be provided suitable for securing berth to deck. Base shall be equipped with means for leveling when installed aboard ship.
6.8 The mattress and box spring shall be manufactured in accordance with Specification F 1085. Mattress and box spring sizes shall be as specified in Table 3.

6.9 Berths may be made in sections: base, drawer section, and berth pan. At the option of the furniture manufacturer, the berth pan section may be furnished as an integral part of the drawer section or as a separate unit. The base shall be suitable for securing to the deck. The other sections shall be attached to the base and to each other so as to form a unit that is adequately

secured and capable of resisting motions of the vessel. Berths shall have backs suitable for securing to bulkheads.

6.10 The drawer for stowing life preservers shall be identified by the words “life preserver” in letters 1/4 in. (6.4 mm) high on the face of the drawer.

6.11 Berths supplied in accordance with this specification will use pipe, side lee rails.

6.12 Pipe lee rail shall be 1-in. (25.4-mm) outside diameter by 0.065-in. (1.65-mm) cold-drawn buttweld carbon steel tubing per Specification A 512. Equal strength pipe rail of aluminum or other metals in appropriate finishes can be supplied, if so specified in the ordering documents.

7. Performance Requirements

7.1 The completed berth assembly with drawers installed, but without a mattress or box spring, shall satisfy the corresponding performance requirements of the following:

7.1.1 Specification F 825.

7.1.2 The berths, without mattress or box springs, shall be capable of supporting a minimum vertical load of 500 lb (4.90 kN) applied uniformly over the entire sleeping surface or a single 250-lb (2.45-kN) vertical load applied over a 1-ft² (0.093-m²) area anywhere on the berth, without causing permanent deformations.
8. Dimensions

8.1 For dimensions, see Table 1 and Table 2.

9. Workmanship, Finish, and Quality Assurance

9.1 All workmanship and material shall be of specified quality in keeping with the best commercial marine practice so as to produce each item suitable for its intended use.
9.2 All exposed burrs and raw or sharp edges that might be injurious to personnel or damage linens shall be removed.
9.3 Depressions considered unacceptable for the product’s end use shall be spot filled and sanded smooth.
9.4 All steel surfaces, unless corrosion resistant or with a corrosion resistant plating, shall be painted so as to prevent corrosion.

10. Inspection and Certification

10.1 The manufacturer shall inspect and certify that the item of furniture complies with this furniture specification and the loading requirements as defined in Section 7.

11. Packaging and Package Marking

11.1 Each item shall be marked in accordance with the purchase order.
11.2 Packaging shall be provided and shall be acceptable to a common carrier.

12. Keywords

12.1 berth; box spring; lee rail; marine; marine berth; mattress; ship
1. Scope

1.1 This specification covers single- and double-compression and self-closing faucets for shipboard plumbing installations.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 The following precautionary caveat pertains only to the test methods portion, Section 10, of this standard. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

MIL-STD-105 Sampling Procedures and Tables for Inspection by Attributes
MIL-STD-129 Marking for Shipment and Storage

2.5 Military Standards:
MIL-STD-162 Naval Sea Systems Command (NAVSEA): NAVSEA Drawing 803-5959206 Faucet, Metering
NAVSEA Drawing 805-1623970 Unit, Lavatory for Officers Station

3. Classification

3.1 Faucets shall be of the following types and classes as specified (see 4.1):

3.1.1 Type I—Standard (bibb):
3.1.1.1 Class A—Compression, plain end.
3.1.1.2 Class B—Compression, hose end.
3.1.1.3 Class C—Self-closing.

3.1.2 Type II—Lavatory, self-closing, low spout:
3.1.2.1 Class A—Fast-closing.
3.1.2.2 Class B—Slow-closing, depression type.

3.1.3 Type III—Folding lavatory, self-closing.

3.1.4 Type IV—Elbow operated.

3.1.5 Type V—Lavatory, combination water supply and drain fixture.

3.1.6 Type VI—Combination supply fixture swing spout for use on galley sinks.

3.1.7 Type VII—Single supply fixture swing spout for use with steam kettles and urns.

3.1.8 Type VIII—Supply fixture for pressed metal and shock mounted china lavatories.

3.1.9 Type IX—Lavatory, combination water supply and drain fixtures, depression type.

4. Ordering Information

4.1 Orders for equipment under this specification shall include the following information, as required, to describe the equipment adequately:

4.1.1 ASTM designation and year of issue,
4.1.2 Type and class of faucet required (see 3.1),
4.1.3 Type of handle required (see 6.11),
4.1.4 Marking required for handles (see 13.1),
4.1.5 Size and weight of Type I faucet required (see 7.1),
4.1.6 Overall dimensions for Type II faucets (see 7.2),
4.1.7 Shank design for Type II, Class B faucets (see 6.2.3.2),
4.1.8 Overall dimensions and position of inlet (side or bottom) for Type III faucets (see 7.3),
4.1.9 Overall dimensions and whether spray is required for Type IV faucets (see 6.4.1.3 and 7.4),
4.1.10 Length of spout for Type VI fixtures (see 7.6.1),
4.1.11 Whether escutcheon plates are provided for Type VI faucets (see 6.6.3),
4.1.12 Whether connections are other than ¼-in. nominal pipe size (NPS) (see 6.8.2.1),
4.1.13 Sample size for examination and testing (see 10.1, 10.2, and 11.1), and
4.1.14 Optional requirements, if any (see Supplementary Requirements S1 through S3).

5. Materials
5.1 Faucet bodies shall be made of bronze conforming to Specification B 62 or Specification B 584.
5.2 Handles shall be of commercial grade cast or forged brass or bronze.
5.3 Bonnets, handwheels, and nuts shall be of commercial quality brass or bronze; machine screws shall be made of commercial brass.
5.4 Seat washers shall be of a rubber or fiber material capable of withstanding the hydrostatic test of 10.1 and suitable for water temperature from 30 to 190°F (−1 to 88°C) without deterioration of material.
5.5 Springs for self-closing faucets shall be of corrosion-resistant steel, phosphor bronze, or nickel copper.

6. Requirements
6.1 Type I, standard.
6.1.1 Type I faucets shall be in accordance with Fig. 1.
6.1.1.1 Faucets shall have hexagon shoulders and a male threaded inlet.
6.1.2 Class A faucets shall be plain; Class B shall have ¼-in. (19-mm) hose thread. Class C shall be the same as Class A except they shall be self-closing.
6.2 Type II, lavatory, self-closing, low spout.
6.2.1 Faucets shall be provided with a shank, fitted with a metal washer and locknut and with a ¼-in. NPS tailpiece.
6.2.1.1 The shank of the faucet and one end of the tailpiece shall be arranged as a ground joint union; the other end of the tailpiece shall be provided with outside threads ¼-in. NPS.
6.2.2 Class A lavatory faucets shall be in accordance with Fig. 2.
6.2.2.1 They shall operate on a cam, ball, or roller bearings.
6.2.2.2 Faucets with renewable operating units may be used.
6.2.3 Class B lavatory faucets shall be in accordance with Fig. 3.
6.2.3.1 They shall be fitted with an adjusting device, which cannot be tampered with, for regulating the closing from 3 to 20 s in accordance with NAVSEA Drawing 803-5959206.
6.2.3.2 Shank design shall be as specified (see 4.1.7).
6.3 Type III, folding lavatory self-closing.
6.3.1 Faucets shall be in accordance with Fig. 4.
6.3.1.1 They shall be of the cam, ball or roller bearing type.
6.3.1.2 The body shall be designed for back mounting.
6.4 Type IV, elbow operated.
6.4.1 Faucets shall be in accordance with Fig. 5 except that a gooseneck spout is acceptable.
6.4.1.1 They shall have a double faucet with a rigid spout with or without buttons, renewable seats, and sleeves or renewable units and integral stops in shanks with union inlets.
6.4.1.2 Escutcheon plates shall be provided for the fixtures.
6.4.1.3 Spray shall be provided when specified (see 4.1.9).
6.5 Type V, lavatory, combination water supply and drain fixtures.
6.5.1 Fixtures shall be in accordance with Fig. 6.
6.5.1.1 The trunion lugs shall be designed so that the trunions will be held in place by spring clips or other device.
6.6 Type VI, combination supply fixture swing spout for use on galley sinks.
6.6.1 Fixtures shall be in accordance with Fig. 7.

6.6.2 Fixtures shall have manifolded hot and cold compression type faucets, discharging through a common swing spout.

6.6.2.1 The swing joint shall be of rugged design and packed with material resistant to water and leakage at temperatures of 30 to 200°F (−1 to 93°F).

6.6.3 The faucets shall have renewable seats, sleeves, or renewable units and steps in the body and shanks with union inlet connection, with or without escutcheon plates as specified (see 4.1.11).

6.7 Type VII, single-supply fixture swing spouts for use with steam kettles and urns.

6.7.1 Fixtures shall be in accordance with Fig. 8.

6.7.1.1 They shall consist of a single-globe-type valve with NPS threaded inlet and outlet and an adaptor designed to receive a swing spout.

6.7.1.2 The swing joint shall be ruggedly constructed and fitted with packing material resistant to leakage and water at temperatures of 30 to 200°F (−1 to 93°C).
6.7.2 Class A or B spouts may be of cast or extruded construction.
6.7.3 Class A or B spouts shall be designed for installation on the valve.
6.8 Type VIII, supply fixture for pressed metal and shock mounted china, lavatories.
6.8.1 Fixtures shall be in accordance with Fig. 9.
6.8.2 Fixtures shall consist of a manifold incorporating hot and cold water NPS female threaded inlet connections to permit connection from top or bottom of the manifold and common outlet (through direct compression type or inverted compression type) faucets.
6.8.2.1 Unless otherwise specified (see 4.1.12), the connections shall be ½-in. NPS.
6.8.3 Faucets shall be of the self-closing type operating on a cam, ball, or roller bearing.
6.8.4 The faucet may seat with or against the water supply pressure.
6.8.5 Faucets with renewable operating units will be acceptable.
6.9 Type IX, lavatory, combination water supply and drain fixtures, depression type.
6.9.1 In addition to the requirements specified herein, Type IX fixtures shall also be in accordance with NAVSEA Drawing 803-5959206.
6.10 Threads for threaded parts shall conform to the applicable requirements of ANSI B1.1.
6.11 Handles shall be four-ball, four-arm, star, T, loose-key T, or lever type, as specified (see 4.1.3), with the exception noted in 6.11.1.
6.11.1 Handles for Type II, Class B and Type IX faucets shall be in accordance with NAVSEA Drawing 803-5959206.
6.11.2 Handwheels may be provided for Type VII faucets.

7. Dimensions, Mass, and Permissible Variations
7.1 Type I faucets shall be of the sizes and weights specified in Table 1.
7.2 Type II faucets shall be of the dimensions specified in 4.1.6.
7.2.1 Dimensions shown on Fig. 3 are approximate.
7.2.2 Faucets shall have a minimum weight, including the tailpiece, of 1.5 lb (0.7 kg) ± 5%.
7.3 For Type III faucets, overall dimensions and position of the inlet (side or bottom) shall be as specified (see 4.1.8). The dimensions shown on Fig. 4 are approximate.
7.4 For Type IV faucets, overall dimensions shall be as specified (see 4.1.9). The dimensions shown on Fig. 5 are approximate.
7.5 Type V fixtures shall conform to the dimensions shown on Fig. 6.
7.6 Type VI fixtures shall conform to the dimensions shown on Fig. 7.
7.6.1 The swing spout shall be 8- or 14-in. (203- to 356-mm) minimum length, as specified (see 4.1.10).
7.7 Type VII fixtures shall conform to the dimensions shown on Fig. 8.
7.8 Type VIII fixtures shall conform to the dimensions shown on Fig. 9.
7.9 Type IX fixtures shall conform to the dimensions shown on NAVSEA Drawing 803-5959206.

8. Workmanship, Finish, and Appearance
8.1 Faucets shall be true to form and free from all defects or blemishes affecting the appearance or serviceability.
8.2 Before plating, faucets shall be thoroughly cleaned of sand and scale by the acid-bath process (or a process satisfactory to the purchaser) and shall have all fins and roughness removed and polished.
8.3 Nickel chromium plating shall be applied to surfaces normally visible after installation including exposed bolts, nuts, screws, or other fastenings.
8.3.1 Nickel plating on copper-base alloys shall be Class 1, Type VII (QC) in accordance with QQ-N-290.
8.3.2 Chromium plating, over nickel, shall be Class 1, Type I in accordance with QQ-C-320.

9. Sampling
9.1 All faucets of the same type, class, and size offered for delivery at one time shall be considered a lot for purposes of examination and hydrostatic test.

10. Test Methods
10.1 Samples, as specified (see 4.1.13), shall be tested under a hydrostatic pressure of 100 psi (690 kPa).

### TABLE 1 Size and Weight of Type I Faucets

<table>
<thead>
<tr>

</tr>
<tr>
<td>1 1/4</td>
<td>1 1/4</td>
</tr>
</tbody>
</table>

*1 in. = 25.4 mm; 1 lb = 0.45 kg.*
10.1.1 Faucets that do not operate satisfactorily or that show leakage shall not be offered for delivery.

10.2 For Type IX fixtures, samples, as specified (see 4.1.13), shall be tested for metering requirements specified on NAVSEA Drawing 803-5959206 by timing the open to close cycle time at 20-psi (140-kPa) inlet pressure and at 100-psi (690-kPa) inlet pressure.

10.2.1 Cycle time at 20 psi (140 kPa) shall not exceed 20 s, and cycle time at 100 psi (690 kPa) shall not be less than 3 s.

10.2.2 Each sample faucet shall be cycled a minimum of ten times under the pressures noted.

10.2.3 Failure to operate within the specified times or to be tight after each cycle shall be cause for rejection.

11. Inspection

11.1 Sample valves, as specified (see 4.1.13), shall be visually and dimensionally examined to determine conformance with the specified design, inclusion of all required parts, proper assembly, and the existence of proper marking and dimension.

11.2 Unless otherwise specified in the contract or purchase order, the contractor is responsible for the performance of all inspection requirements as specified herein.

11.2.1 Except as otherwise specified in the contract or purchase order, the contractor may use his own or any other facilities suitable for the performance of the inspection requirements specified herein unless disapproved by the purchaser.

11.2.2 The purchaser reserves the right to perform any of the inspections set forth in the specification where such inspections are deemed necessary to ensure that supplies and services conform to prescribed requirements.

11.2.3 The absence of any inspection requirements in the specification shall not relieve the contractor of the responsibility of ensuring that all products or supplies submitted to the purchaser for acceptance comply with all requirements of the contract.

12. Rejection and Rehearing

12.1 Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier may make claim for a rehearing.

13. Product Marking

13.1 All handles shall be marked “hot” or “cold” as specified (see 4.1.4). Substitution of “H” or “C” is permissible for “hot” or “cold,” respectively. Type II, Class B and Type IX faucets shall be marked in accordance with NAVSEA Drawing 803-5959206.

13.1.1 Type V faucets shall also have a handle marked with “D” (see Fig. 6).

13.2 Each faucet shall be legibly stamped before, or etched after, plating, with the name or identification mark of the manufacturer.

14. Packaging

14.1 Unless otherwise specified (see 4.1.14), packaging shall conform to the manufacturer’s normal commercial practice, and in such a manner that will ensure acceptance by common carrier and afford protection against physical and mechanical damage during shipment.

14.2 Packing shall be accomplished in a manner that shall ensure acceptance by common carrier at the lowest rate and shall afford protection against physical or mechanical damage during direct shipment from the supply source to the using activity for early installation.

15. Keywords

15.1 compression faucets; faucets; marine; plumbing; self-closing faucets; ship; shipboard

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract or order (see 4.1.14).

S1. Referenced Documents

S1.1 The following documents are applicable only when one or more of the requirements of S2 or S3 are specified in the contract or order (see 4.1.14): Federal Specifications PPP-B-566, PPP-B-585, PPP-B-591, PPP-B-601, PPP-B-621, PPP-B-636, and PPP-B-676; Military Specification MIL-P-116; Military Standards MIL-STD-105 and MIL-STD-129; and NAVSEA Drawing 805-1623970.

S2. Preparation for Delivery

S2.1 The requirements for packaging, packing, and marking for shipment shall be as specified by the contractor for domestic shipment and storage or overseas shipment.

S2.2 Packaging—The faucets shall be packaged in accordance with Method III of MIL-P-116. Unit and intermediate containers shall conform to PPP-B-566, PPP-B-676, or PPP-B-636. Quantity per unit and intermediate container shall be as specified by the purchaser.

S2.3 Packing shall be Level A or B, as specified (see 4.1.14).

S2.3.1 Level A—The faucets, packaged as specified (see 14.1 or S2.2.1), shall be packed in containers conforming to any one of the following specifications at the option of the supplier: PPP-B-591, Class II; PPP-B-601, overseas type; PPP-B-621, Class 2; PPP-B-585, Class 3; or PPP-B-636, Type SF, weather-resistant class.
S2.3.1.1 The gross weight of wood-type boxes shall not exceed 200 lb (90 kg); fiberboard boxes shall not exceed the weight limitations of the applicable box specification. Closures shall be in accordance with the applicable box specification and appendix thereto.

S2.3.2 Level B—The faucets, packaged as specified (see 14.2 or S2.2.1), shall be packed in containers conforming to any one of the following specifications at the option of the supplier: PPP-B-591, Class I; PPP-B-601, Domestic; PPP-B-621, Class 1; PPP-B-585, Class 1; or PPP-B-636, Type SF, domestic class.

S2.3.2.1 The gross weight of wood-type boxes shall not exceed 200 lb (90 kg); fiberboard boxes shall not exceed the weight limitations of the applicable box specification. Closures shall be in accordance with the applicable box specification and appendix thereto.

S2.4 In addition to any special marking required in the contract or order (see 4.1.14), marking of the packages and shipping containers shall be in accordance with MIL-STD-129.

S2.5 Inspection of Packaging—Sample packages and packs, and the inspection of the preservation packaging, packing, and marking for shipment and storage, shall be in accordance with the requirements of Supplementary Requirement S2 and the documents specified therein.

S3. Special Government Requirements

S3.1 Provisioning:

S3.1.1 Provisioning technical documentation (PTD), spare parts, and repair parts shall be furnished as specified in the contract (see 4.1.14).

S3.1.2 When ordering spare parts or repair parts for the equipment covered by this specification, the contract shall state that such spare parts and repair parts shall meet the same requirements and quality assurance provisions as the parts used in the manufacture of the equipment. Packaging for such parts should also be specified.

S3.1.3 On-board repair parts shall be furnished for shipboard installations in accordance with Table S3.1 for each type valve installed, with the exception of Type IX valves, which shall be in accordance with NAVSEA Drawing 803-5959206.

S3.1.4 Type V faucets and repair parts for Type V faucets are for replacement or repair of existing lavatories only. For lavatories in accordance with NAVSEA Drawing 805-1623970, Type IX, combination water supply and drain fixture shall be supplied.

S3.2 Sampling—Faucets from each lot (see 9.1) shall be selected in accordance with Inspection Level I of MIL-STD-105 for examination (see 11.1) and hydrostatic pressure test (see 10.1). The acceptable quality level (AQL) shall be 1.5 % defective.

Standard Practice for Preparing and Locating Emergency Muster Lists

INTRODUCTION

Title 33 and Title 46 of the Code of Federal Regulations (CFR) and the Safety of Life at Sea Convention (SOLAS) contain requirements for muster lists. Emergency muster lists are required to be on board tank vessels, passenger vessels, cargo vessels, oceanographic research vessels, nautical school ships, mobile offshore drilling units (MODUs), and outer continental shelf (OCS) facilities other than MODUs. This practice is a consolidated source for muster list requirements, combining requirements from all of the subparts of the Code of Federal Regulations listed above and SOLAS 1974 as amended through 1996.

1. Scope

1.1 This practice sets forth the elements to be included in an emergency muster list, including emergency signals, and its location on a vessel or facility. This practice also includes emergency instructions for passengers.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 Code of Federal Regulations:
Title 33 Navigation and Navigable Waters
Title 46 Shipping
2.2 Safety of Life at Sea Convention.
SOLAS 74 Internation Convention for the Safety of Life at Sea, 1974 (as amended)

2.3 Other Document:
IMO Resolution A.760(18) Symbols Related to Life-Saving Appliances and Arrangements

3. Significance and Use

3.1 Muster lists are intended to provide both an effective plan for assigning personnel stations and duties in the event of any foreseeable emergency, as well as a quick visual reference that a crewmember can look at to find out where to go, what to bring, and what duties to perform in the event of an emergency and must be posted at all times.

3.2 The station bill has been changed to muster list. The term station bill may be used optionally.

3.3 Since no two classes of vessels or facilities are identical, muster lists must be tailored for individual vessels or facilities.

3.4 Muster lists are intended to be posted in conspicuous locations throughout the vessel for the use of the crew.

3.5 Posted muster lists shall be at least 600 by 750 mm (24 by 30 in.).

3.6 Muster lists shall outline the special duties and duty stations for each member of the crew, including the chain of command, for the various emergencies.

3.7 As far as possible, duties shall be comparable with the regular work of the individual.

3.8 The muster list shall set forth the various signals to be used for the calling of the crew to their stations and for giving instructions to them while at their stations as outlined in Section 4.

---

This practice is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.

^1 This practice is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.

^4 Available from the International Maritime Organization, 4 Albert Embankment, London SE1 7SR, UK.
3.9 The muster list shall illustrate the purpose of controls.
3.10 The muster list shall illustrate the procedure for operating the launching device.
3.11 The muster list shall give relevant instructions or warnings.
3.12 The muster list should be able to be seen easily under emergency lighting conditions.
3.13 The muster list must also display the symbols in accordance with IMO Resolution A.760(18).
3.14 The final muster list should be as simple as possible; and an accurate and up-to-date muster list should be maintained.

4. Procedure

4.1 Fig. 1 is provided as a sample muster list.
4.2 Each muster list shall be at least poster size (600 by 750 mm (24 by 30 in.
).
4.3 Each muster list shall specify the following:
4.3.1 Instructions for operating the general alarm system,
4.3.2 Identification of the emergency signals,
4.3.3 The action to be taken by crew and passengers when each signal is sounded,
4.3.4 How the order to abandon the vessel will be given,
4.3.5 The survival craft to which each person on board is assigned,
4.3.6 The officers who are assigned to ensure that lifesaving and fire-fighting appliances are maintained in good condition and are ready for immediate use,
4.3.7 Substitutes for key persons in the event that those persons are disabled, taking into account that different emergencies require different actions,
4.3.8 The duties assigned to the different members of the crew, including:
4.3.8.1 Persons in command and the chain of command,
4.3.8.2 Closing of watertight doors, fire doors, valves, scuppers, sidescuttles, skylights, portholes, and other similar openings in the vessel’s hull,
4.3.8.3 Stopping of fans and ventilating systems,
4.3.8.4 Equipping survival craft and other lifesaving appliances,
4.3.8.5 Preparation and launching of survival craft,
4.3.8.6 General preparations of other lifesaving appliances,
4.3.8.7 Muster of passengers and other persons in addition to the crew,
4.3.8.8 Use of communication equipment,
4.3.8.9 Responsibility for two-way radiotelephone apparatus and other portable emergency radiocommunication equipment not stowed in survival craft or rescue boats,
4.3.8.10 Manning of rescue boats for rescuing persons overboard and other emergencies requiring the use of the rescue boat,
4.3.8.11 Manning of emergency squad assigned to deal with fires and other emergencies,
4.3.8.12 Administration of first aid,
4.3.8.13 The passenger vessel muster list should include the procedures for locating and rescuing persons who may be trapped in the staterooms,
4.3.8.14 Special duties assigned with respect to the use of fire-fighting equipment and installations, and
4.3.8.15 Such other duties as are necessary for the proper handling of the vessel in an emergency.
4.3.9 The duties assigned to members of the crew, generally from the steward’s department, in relation to passengers in case of emergency, including:
4.3.9.1 Warning passengers and other persons on board,
4.3.9.2 Seeing that passengers are suitably dressed and have donned their lifejackets or immersion suits correctly,
4.3.9.3 Assembling passengers at muster stations,
4.3.9.4 Keeping order in the passageways and on the stairways and generally controlling the movements of the passengers, and
4.3.9.5 Making sure that a supply of blankets is taken to survival craft.
4.4 Where the size of the crew permits, the muster list on a passenger vessel shall include an emergency squad organized by the master to form the nucleus of a damage control party. This squad consists of persons specially trained in the use of the emergency and rescue equipment and generally familiar with the vessel and fundamentals of damage control.
4.5 On MODUs and OCS facilities, the requirements in 4.3 applying to the crew also include the industrial personnel assigned to the unit. The requirements in 4.3 that apply to passengers also apply to visitors and other persons on board not regularly employed on the unit. In addition to the requirements in 4.3, the muster list shall cover the following:
4.5.1 The duties of the crew in case of collisions or other serious casualties, and
4.5.2 The duties of the crew in case of severe storms.
4.6 Emergency instructions and illustrations for posting in passenger cabins and at muster stations shall be in English and may also be in any other appropriate language. The instructions and illustrations shall inform passengers of the following:
4.6.1 The fire and emergency signal,
4.6.2 The abandon ship signal,
4.6.3 Their muster station,
4.6.4 The essential actions they shall take in an emergency,
4.6.5 The method of donning lifejackets, incorporating fully illustrated instructions,
4.6.6 The location of immersion suits and lifejackets, if they are provided for passengers, including child-size immersion suits and lifejackets,
4.6.7 The method of donning immersion suits, if immersion suits are provided for passengers, including fully illustrated instructions, and
4.6.8 The location of thermal protective aid for each person not provided with an immersion suit on passenger vessels.
4.7 The muster list for nautical school ships shall include the muster of all persons aboard in the duties assigned.
4.8 Vessels other than MODUs and OCS facilities shall use the following signals:
4.8.1 The fire alarm signal shall be a continuous blast of the whistle for not less than 10 s supplemented by the continuous ringing of the general alarm bells for not less than 10 s.
4.8.2 For dismissal from fire alarm stations, the general alarm shall be sounded three times supplemented by three short blasts of the whistle.
**MUSTER LIST**

**GENERAL INSTRUCTIONS**

1. Each crew member shall familiarize himself/herself with the location of his/her respective station and assigned duties immediately reporting aboard.

2. All persons reporting to emergency stations shall be fully dressed including a hat and shoes, and shall carry a flashlight, if possible.

3. Immediately upon sounding of an alarm contact shall be made by the Department Heads with the Master. Channel 1 is the designated Emergency Channel on the Handi-Talkie. All initial contact persons with duties listed below are to furnish specific information to the Department Heads until requested by the Captain.

4. A person discovering a fire shall immediately notify the Captain who shall immediately report the fire by any available means.

5. Upon hearing a "Man Overboard", immediately throw a life preserver into the water and pass the word to the bridge "Man Overboard Port/Starboard Side" if in sight the lifeguard should keep lifeguard at a safe distance.

6. In an emergency and for all drills, extra persons will muster at the hospital/treatment room.

**FIRE AND EMERGENCY STATIONS**

**FIRE AND EMERGENCY SIGNAL**

Continuous sounding of the ship's whistle for a period of not less than ten (10) seconds supplemented by the same signal on the General Alarm Bell.

**DISMISSEL SIGNAL**

Three (3) short blasts of the ship's whistle supplemented by the same signal on the General Alarm Bell.

**MAN OVERBOARD SIGNAL**

Sounding of the letter "M" on the ship's whistle several times and then supplemented by the same signal on the General Alarm Bell.

**NOTE:** Extra persons will muster at the hospital/treatment room.

---

**ABANDON SHIP STATIONS**

Severe (3) short blasts on the whistle followed by one (1) long blast, supplemented by the same signal on the General Alarm Bell.

**FIG. 1 Sample Format for Must List**

3
4.8.3 The signal for boat stations or abandon ship drill shall be a succession of more than six short blasts followed by one long blast of the whistle supplemented by a comparable signal on the general alarm bells.

4.8.4 Where whistle signals are used to handle the lifeboats and davit-launched life rafts, they shall be as follows:
   4.8.4.1 To lower the lifeboats and davit-launched life rafts, one short blast, and
   4.8.4.2 To stop lowering the lifeboats and davit-launched life rafts, two short blasts.

4.8.5 For dismissal from boat stations, there shall be three short blasts of the whistle.

4.8.6 In the case of river vessels, the ship’s bell may be used instead of the whistle signals stipulated in this section.

4.8.7 The master of any vessel may establish such other emergency signals, in addition to 4.8.1 through 4.8.6, as will provide that all officers, crew, and passengers will have positive and certain notice of the existing emergency. Each additional emergency signal established shall not conflict with navigational signals or other general alarm signals.

4.9 Muster lists for MODUs and OCS facilities other than MODUs shall include instructions on the following additional items:
   4.9.1 Warning personnel of the emergency,
   4.9.2 Instructing all personnel on use and wearing of life preservers and exposure suits (if carried), and
   4.9.3 Directing personnel to appointed stations.

4.9.4 The muster list shall set forth signals that accomplish the following:
   4.9.4.1 Call personnel to their stations, and
   4.9.4.2 Direct personnel at their stations.

4.10 Emergency stations signals for MODUs and OCS facilities other than MODUs are established as follows:
   4.10.1 The signal to man emergency stations is a rapid succession of short soundings of both the general alarm bell and the whistle, if a whistle is installed, for a period of not less than 10 s.
   4.10.2 The signal to secure from emergency stations is three short soundings of both the general alarm bell and the whistle, if a whistle is installed.
   4.10.3 The signal to man abandoned unit stations is a continuous sounding of both the general alarm and the whistle, if a alarm and the whistle, if a whistle is installed.
   4.10.4 If whistle signals are used to direct handling of lifeboats and davit-launched life rafts, they shall be sounded as follows:
      4.10.4.1 One short blast to lower lifeboats and davit-launched life rafts, and
      4.10.4.2 Two short blasts to stop lowering the lifeboats and davit-launched life rafts.
   4.10.5 The signal to secure from abandoned unit stations is three short soundings of both the general alarm bell and the whistle, if a whistle is installed.

Standard Specification for
Spill Valves for Use in Marine Tank Liquid Overpressure
Protections Applications

1. Scope
1.1 This specification provides the minimum requirements for design, construction, performance, and testing of devices to prevent marine tank liquid overpressurization (hereafter called spill valves).
1.2 The spill valves provided in accordance with this specification will satisfy Regulation II-2/59.1.6 of the 1981 and 1983 Amendments to the International Convention for the Safety of Life at Sea, 1974 (SOLAS), which states: “Provision shall be made to guard against liquid rising in the venting system to a height which would exceed the design head of the cargo tank. This shall be accomplished by high level alarms or overflow control systems or other equivalent means, together with gaging devices and cargo tank filling procedures.”
1.3 The spill valves are not intended for the venting of vapors or the relief of vapor overpressurization or underpressurization of marine tanks.
1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.
1.5 The following precautionary caveat pertains only to the test methods portion, Section 8, of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

   46 CFR 153 Ships Carrying Bulk Liquid, Liquified Gas, or Compressed Gas Hazardous Materials

3. Terminology
3.1 Definition:
3.1.1 spill valve—an independent device that automatically prevents liquid overpressurization of a tank by relieving liquid at a predetermined pressure set higher than the pressure reached in the tank when the tank vapor relieving device operates at its maximum design venting rate (based on a volumetric vapor volume 1.25 times the maximum design loading rate).

4. Ordering Information
4.1 Orders for spill valves in accordance with this specification shall include the following information, as applicable:
4.1.1 Nominal pipe size and end connections,
4.1.2 Product(s) in tank being protected by the spill valve,
4.1.3 Inspection and tests other than specified by this specification,
4.1.4 Required relieving pressure at maximum tank loading flow rate,

---

qualified in accordance with Section IX of the ASME Code.

4.1.7 Inlet pressure drop resulting from the maximum tank design loading flow rate.

4.1.9 Purchaser’s inspection requirements (see 9.1).

4.1.10 Installation inclinations in excess of 2 1/2 ° (see 6.6).

4.1.11 Purchaser’s specifications for preventing the valve from leaking due to cargo sloshing, and

4.1.12 Additional requirements or testing as contracted by the manufacturer and the purchaser.

5. Materials

5.1 Materials of construction shall be suitable for the service intended and resistant to the attack by the liquid carried in the tank being protected (see 4.1.2). Table I of 46 CFR 153 specifies materials that may not be used in components that contact liquid or vapor of each hazardous liquid cargo.

5.2 Housings of spill valves, and all other parts or bolting, or both, used for pressure retention, shall be constructed of materials having a solidus melting point of greater than 1700°F (927°C) and be listed in ANSI B 31.1 or Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code, except as noted in 5.5.

5.3 Corrosion-resistant materials shall be used for the following:

5.3.1 Housings, disks, spindles, and seats of valves.

5.3.2 Springs that actuate disks of valves. Springs plated with corrosion-resistant material are not acceptable.

5.4 Nonmetallic materials shall not be permitted except for gaskets, seals, bushings in way of moving parts, and valve diaphragms.

5.5 Bolting materials shall be at least equal to those listed in Table 1 of ANSI B 16.5. Bolts, screws, and fasteners in contact with interior liquid shall be compatible with the liquid (see 4.1.2).

6. Other Requirements

6.1 Pressure-retaining housings shall be designed to withstand a hydrostatic pressure of at least 125 lb/in.² (8.78 kg/cm²) without rupturing or showing permanent distortion.

6.2 Housing shall have suitable pipe connections for the removal, maintenance, and testing of the spill valve.

6.2.1 Threaded or flanged pipe end connections shall comply with the applicable B 16 ANSI standards listed in 2.2 or as agreed upon by the manufacturer and the purchaser (see 4.1.12). Welded joints shall comply with Specification F 722.

6.3 The design of spill valves shall allow for ease of inspection and removal of internal elements for replacement, cleaning, or repair without removal of the spill valve.

6.4 All flat joints of the housing shall be machined true and shall provide for a joint having adequate metal-to-metal contact.

6.5 Where welded construction is used, welded joint design details, welding, and nondestructive testing shall be in accordance with Section VIII, Division 1 of the ASME Code and Specification F 722. Welders and weld procedures shall be qualified in accordance with Section IX of the ASME Code.

6.6 The spill valve shall be fully operable at static inclinations up to 2 1/2 ° unless otherwise specified by the ordering information in Section 4.

6.7 Spill valves shall allow for efficient drainage of moisture without impairing their proper operation.

6.7.1 Where the design does not permit complete drainage of condensate through its connection to the tank, the housing shall be fitted with a plugged drain opening on the side of the atmospheric outlet of not less than nominal pipe size 1/2 in. (12 mm).

6.8 Housing, elements, and seal gasket materials shall be capable of withstanding the highest pressure and temperature to which the spill valve may be exposed under normal conditions.

6.9 Spill valves shall be vapor tight at pressures below the rated liquid relieving pressure.

6.10 Fastenings essential to the operation of the spill valve shall be protected against loosening.

6.11 Spill valves shall be designed and constructed to minimize the effect of fouling under normal conditions.

6.12 The spill valve shall not be provided with a means of positive closure. In installations where cargo sloshing is expected, the spill valve installation must be designed to preclude premature opening of the valve due to cargo sloshing. Also, the installation shall be designed so that it complies with applicable loadline and subdivision requirements.

6.13 Spill valves shall be capable of operating in freezing conditions.

6.14 Each of the free areas through the valve seat and through the valve discharge at maximum lift shall not be less than the cross-sectional area of the valve inlet connection.

6.15 Means shall be provided to check that any valve opens freely and does not remain lodged in the open position.

6.16 Valve Disks:

6.16.1 Valve disks shall be guided by a ribbed cage or other suitable means to prevent binding and ensure proper seating. Where valve stems are guided by bushings suitably designed to prevent binding and to ensure proper seating, the valves need not be fitted with ribbed cages.

6.16.2 Valve disks shall close tight against the valve seat by metal to metal contact; however, resilient seating seals may be provided if the design is such that the disk closes tight against the seat in case the seals are destroyed or in case they carry away.

6.16.3 Valve disks may be solid or hollow. The pressure at which the valve disks open fully at maximum flow rating shall not exceed 120 % of the set (opening) pressure.

6.17 Valves may be actuated by nonmetallic diaphragms.

6.17.1 Nonmetallic diaphragms are not allowed where failure results in unrestricted flow of flammable or toxic tank vapors to the atmosphere or in an increase in the pressure at which the valve normally releases.

6.18 Relief pressure adjusting mechanisms shall be permanently secured by lockwire, locknuts, or other suitable means.

6.18.1 Hollow portions of the valve used to vary the relieving pressure by adding or removing weight shall be watertight.
6.18.2 Spill valves shall not permit entrance of water when exposed to boarding seas.

7. Workmanship, Finish, and Appearance

7.1 Spill valves shall be of first class workmanship and free from imperfections that may affect their intended purpose.

7.2 Each finished spill valve shall be visually and dimensionally checked to ensure that the spill valve corresponds to this specification, is certified in accordance with Section 10, and is marked in accordance with Section 11.

8. Test Methods

8.1 Prototype Tests:

8.1.1 A prototype of the largest and smallest spill valve of each design, based on valve inlet connection size, shall be tested as specified in 8.1.5, 8.1.6, and8.1.8 through 8.1.10. Additionally, all models shall be tested as specified in 8.1.7.

8.1.2 The spill valve shall have the dimensions of and most unfavorable clearances expected in production units.

8.1.3 Tests shall be conducted by a laboratory capable of performing the tests.

8.1.4 A test report shall be prepared by the laboratory that shall include:

8.1.4.1 Detailed drawings of the spill valve,
8.1.4.2 Types of tests conducted and results obtained,
8.1.4.3 Specific advice on approved attachments,
8.1.4.4 Types of liquid for which the spill valve is approved,
8.1.4.5 Drawings of the test rig,
8.1.4.6 The pressures at which the spill valve opens and closes and the efflux flow rate at various inlet pressures,
8.1.4.7 Records of all markings found on the prototype spill valve, and
8.1.4.8 A traceable report number.

8.1.5 Corrosion Test—A corrosion test shall be conducted in accordance with Practice B 117. The valve shall be subjected to the test for a period of 240 h and allowed to dry for 48 h. There shall be no corrosion deposits that cannot be washed off.

8.1.6 Hydrostatic Test—A hydrostatic pressure test shall be conducted to show compliance with 6.1. The test shall be made with water or other liquid having a maximum viscosity of 40 SSU at 125°F (52°C) with a maximum pressure test temperature of 125°F (52°C). The minimum duration of the test shall be 1 min. The purpose of this test is to detect leaks and structural imperfections. No visible leakage is permitted.

8.1.7 Performance Tests—Performance characteristics, including flow rates under various positive pressures, operating sensitivity, flow resistance, and velocity, shall be demonstrated by appropriate tests with a representative fluid.

8.1.8 Freeze Test—Simulate water sloshing on deck by spraying a prototype spill valve completely with water from all sides and below using a fully pressurized fire hose. Allow 3 min to drain off. Immediately immerse it in a freeze chamber prechilled to 20°F (-7°C). Hold it in a chamber for 2 h at this temperature. Immediately test the valve as in 8.1.7 to determine opening pressure while frozen. The unit passes the test if it opens within 10 % of its previously measured set (opening) pressure.

8.1.9 Vapor Tightness Test—Compliance with 6.9 shall be demonstrated by testing the spill valve with compressed air at 90 % of the spill valve set (opening) pressure. The test apparatus shall have a total volume of air (in cubic feet) equal to 5 x D, where D is the seat diameter of the spill valve, in inches (test volume may vary by ±10 %). The valve design shall be deemed satisfactory if the air leakage rate is such that the pressure drop is not more than 2 % in 2 h.

8.1.10 Seaworthiness Test—In a simulated installation, immerse the spill valve such that the seal is under 2 ft of water, minimum. Spray it for 10 min with a 2½-in. fire hose with a fully open 7½-in. diameter nozzle at a pitot pressure of 80 psig measured at the open nozzle. Spray all parts of the valve, both immersed and non-immersed, from all angles. The hose nozzle shall not be located further than 10 ft from the spill valve during the course of this test. The valve design is sufficient if leakage through the housing or past the disk, or both, is no more than 1 oz.

8.1.11 After completion of all tests the device shall be disassembled and examined and no part of the device shall be damaged or show permanent deformation.

8.2 Production Tests:

8.2.1 Each finished spill valve is to be tested by a hydrostatic test conducted at 1½ times the rated relieving pressure of the spill valve, with the device secured closed. The test shall be made with water or other liquid having a maximum viscosity of 40 SSU at 125°F (52°C) with a maximum pressure test temperature of 125°F (52°C). The minimum duration of the test shall be 1 min. The purpose of this test is to detect leaks and structural imperfections. No visible leakage is permitted.

8.2.2 Before being shipped, each unit shall be tested as necessary to verify that it will function at its set (opening) pressure and that the disk moves freely and fully.

9. Inspection

9.1 The manufacturer shall afford the purchaser’s inspector all reasonable facilities necessary to satisfy him that the material is being furnished in accordance with this specification. Inspection by the purchaser shall not interfere unnecessarily with the manufacturer’s operations. All examinations and inspections shall be made at the place of manufacture, unless otherwise agreed upon.

10. Certification

10.1 Manufacturer’s certification that a spill valve has been constructed in accordance with this specification shall be provided in an instruction manual. The manual shall include the following:

10.1.1 Installation instructions, including size of the inlet and outlet, approved location for installation, and maximum or minimum length of pipe, if any, between the spill valve and the atmosphere,
10.1.2 Operating instructions,
10.1.3 Maintenance requirements,
10.1.3.1 Instructions on how to determine when spill valve cleaning is required and the method of cleaning,
10.1.4 Copy of prototype test report (see 8.1), and
10.1.5 Product(s) that the valve is designed for or restricted to, or both.
11. Product Marking

11.1 Each spill valve shall be permanently marked indicating the following:

11.1.1 Manufacturer’s name or trademark,
11.1.2 Style, type, model, or other manufacturer’s designation for the spill valve,
11.1.3 Direction of flow through the spill valve,
11.1.4 Maximum rated flow,
11.1.5 ASTM designation of this specification,
11.1.6 Relief pressure setting at full flow rating,
11.1.7 Set (opening) pressure, and
11.1.8 Indication of proper orientation of valve, if critical.

12. Quality Assurance

12.1 Spill valves shall be designed, manufactured, and tested in a manner that ensures they meet the characteristics of the prototype tested in accordance with this specification.

12.2 The spill valve manufacturer shall maintain the quality of the spill valves that are designed, tested, and marked in accordance with this specification. At no time shall a spill valve be sold with this specification designation that does not meet the requirements herein.

13. Keywords

13.1 marine technology; overflow control systems; overpressurization; overpressure protection; ships; spill valves

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for Tank Vent Flame Arresters

This standard is issued under the fixed designation F 1273; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification provides the minimum requirements for design, construction, performance, and testing of tank vent flame arresters.

1.2 This specification is intended for flame arresters protecting systems containing vapors of flammable or combustible liquids where vapor temperatures do not exceed 60°C. The test media defined in 9.1.1 can be used except where arresters protect systems handling vapors with a maximum experimental safe gap (MESG) below 0.9 mm. Flame arresters protecting such systems must be tested with appropriate media (the same vapor or a media having a MESG no greater than the vapor). Various gases and their respective MESG are listed in Table 1.

NOTE 1—Flame arresters meeting this specification also comply with the minimum requirements of the International Maritime Organization, Maritime Safety Committee Circular No. 373 (MSC/Circ. 373/Rev. 1).

1.3 The values stated in either inch-pound or SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The following precautionary caveat pertains only to the test methods portions, Sections 8 and 9, of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.5 This standard should be used to measure and describe the properties of materials, products, or assemblies in response to heat and flame under controlled laboratory conditions and should not be used to describe or appraise the fire hazard or fire risk of materials, products, or assemblies under actual fire conditions. However, results of this test may be used as elements of a fire risk assessment which takes into account all of the factors which are pertinent to an assessment of the fire hazard of a particular end use

F 722 Specification for Welded Joints for Shipboard Piping Systems

F 1155 Practice for Selection and Application of Piping System Materials

B16.5 Pipe Flanges and Flanged Fittings3
2.3 Other Documents:
ASME Boiler and Pressure Vessel Code: Section VIII, Division 1, Pressure Vessels4
ASME Boiler and Pressure Vessel Code: Section IX, Welding and Brazing Qualifications4
International Maritime Organization, Maritime Safety Committee: MSC/Circ. 373/Rev. 1 Revised Standards for the Design, Testing and Locating of Devices to Prevent the Passage of Flame into Cargo Tanks in Tankers5
International Electrotechnical Commission: Publication 79-1 Electrical Apparatus for Explosive Gas Atmospheres6

3. Terminology
3.1 Definitions:
3.1.1 flame arrester—a device to prevent the passage of flame in accordance with a specified performance standard. Its flame arresting element is based on the principle of quenching.
3.1.2 flame passage—the transmission of a flame through a flame arrester.
3.1.3 flame speed—the speed at which a flame propagates along a pipe or other system.
3.1.4 gasoline vapors—a nonleaded petroleum distillate consisting essentially of aliphatic hydrocarbon compounds with a boiling range of approximately 65 to 75°C.

4. Classification
4.1 The two types of flame arresters covered in this specification are classified as follows:
4.1.1 Type I—Flame arresters acceptable for end-of-line applications.
4.1.2 Type II—Flame arresters acceptable for in-line applications.

5. Ordering Information
5.1 Orders for flame arresters under this specification shall include the following information, as applicable:
5.1.1 Type (I or II),
5.1.2 Nominal pipe size,
5.1.3 Each gas or vapor in the tank being protected by the flame arrester and the corresponding MESG,
5.1.4 Inspection and tests other than those specified by this specification,
5.1.5 Anticipated ambient air temperature range,
5.1.6 Purchaser’s inspection requirements (see 10.1),
5.1.7 Description of installation (distance and configuration of pipe between the arrester and the atmosphere or potential ignition source) (see 8.2.4.2),
5.1.8 Materials of construction (see Section 6), and
5.1.9 Maximum flow rate and the design pressure drop for that maximum flow rate.

6. Materials
6.1 The flame arrester housing, and other parts or bolting used for pressure retention, shall be constructed of materials listed in Practice F1155, or Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code.
6.1.1 Arrester, elements, gaskets, and seals shall be of materials resistant to attack by seawater and the liquids and vapors contained in the tank being protected (see 5.1.3).
6.2 Nonmetallic materials, other than gaskets and seals, shall not be used in the construction of pressure-retaining components of the flame arrester.
6.2.1 Nonmetallic gaskets and seals shall be noncombustible and suitable for the service intended.
6.3 Bolting materials, other than those in 6.1, shall be at least equal to those listed in Table 1 of ANSI B16.5.
6.4 The possibility of galvanic corrosion shall be considered in the selection of materials.
6.5 All other parts shall be constructed of materials suitable for the service intended.

7. Other Requirements
7.1 Flame arrester housings shall be gastight to prevent the escape of vapors.
7.2 Flame arrester elements shall fit in the housing in a manner that will ensure tightness of metal-to-metal contacts in such a way that flame cannot pass between the element and the housing.
7.2.1 The net free area through flame arrester elements shall be at least 1.5 times the cross-sectional area of the arrester inlet.
7.3 Housings and elements shall be of substantial construction and designed for the mechanical and other loads intended during service. In addition, they shall be capable of withstanding the maximum and minimum pressures and temperatures to which the device may be exposed under both normal and the specified fire test conditions in Section 9.
7.4 Threaded or flanged pipe connections shall comply with the applicable B-16 standards in Practice F1155. Welded joints shall comply with Specification F722.
7.5 All flat joints of the housing shall be machined true and shall provide for a joint having adequate metal-to-metal contact.
7.6 Where welded construction is used for pressure-retaining components, welded joint design details, welding, and nondestructive testing shall be in accordance with Section VIII, Division 1 of the ASME Code and Specification F722. Welders and weld procedures shall be qualified in accordance with Section IX of the ASME Code.
7.7 The design of flame arresters shall allow for ease of inspection and removal of internal elements for replacement, cleaning, or repair without removal of the entire device from the system.
7.8 Flame arresters shall allow for efficient drainage of condensate without impairing their efficiency to prevent the passage of flame.
7.8.1 Where the design does not permit complete drainage of condensate through its connection to the tank, the housing shall be fitted with a plugged drain opening on the side of the atmospheric outlet of not less than \( \frac{1}{2} \)-in. nominal pipe size (NPS \( \frac{1}{2} \)).

7.9 All fastenings shall be protected against loosening.

7.10 Flame arresters shall be designed and constructed to minimize the effect of fouling under normal operating conditions.

7.11 Flame arresters shall be capable of operating over the full range of ambient air temperatures anticipated.

7.12 End-of-line flame arresters shall be so constructed as to direct the efflux vertically upward.

7.13 Flame arresters shall be of first class workmanship and free from imperfections that may affect their intended purpose.

7.14 Tank vent flame arresters shall show no flame passage when subjected to the tests in 8.2.4.

8. Prototype Tests

8.1 Tests shall be conducted by an independent laboratory capable of performing the tests. The manufacturer, in choosing a laboratory, accepts that it is a qualified independent laboratory by determining that it has (or has access to) the apparatus, facilities, personnel, and calibrated instruments that are necessary to test flame arresters in accordance with this specification.

8.1.1 A test report shall be prepared by the laboratory that shall include the following:

8.1.1.1 Detailed drawings of the flame arrester and its components (including a parts list identifying the materials of construction).

8.1.1.2 Types of tests conducted and results obtained,

8.1.1.3 Specific advice on approved attachments (see 8.2.4.1),

8.1.1.4 Types of gases or vapors for which the flame arrester is approved (see 5.1.3),

8.1.1.5 Drawings of the test rig,

8.1.1.6 Records of all markings found on the tested flame arrester, and

8.1.1.7 A report number.

8.2 One of each model Type I and Type II flame arrester shall be tested. Where approval of more than one size of a flame arrester model is desired, the largest and smallest sizes shall be tested. A change of design, material, or construction that may affect the corrosion resistance, endurance burn, or flashback capabilities of the flame arrester shall be considered a change of model.

8.2.1 The flame arrester shall have the same dimensions, configuration, and the most unfavorable clearances expected in production units.

8.2.2 A corrosion test shall be conducted. In this test, a complete arrester, including a section of pipe similar to that to which it will be fitted, shall be exposed to a 20% sodium chloride solution spray at a temperature of 25°C for a period of 240 h and allowed to dry for 48 h. Following this exposure, all movable parts shall operate properly and there shall be no corrosion deposits that cannot be washed off.

8.2.3 Performance characteristics as declared by the manufacturer, such as flow rates under both positive and negative pressure, operating sensitivity, flow resistance, and velocity, shall be demonstrated by appropriate tests.

8.2.4 Tank vent flame arresters shall be tested for endurance burn and flashback in accordance with the test procedures in Section 9. The following constraints apply:

8.2.4.1 Where a Type I flame arrester is provided with cowls, weather hoods, deflectors, and so forth, it shall be tested in each configuration in which it is provided.

8.2.4.2 Type II arresters shall be specifically tested with the inclusion of all pipes, tees, bends, cowls, weather hoods, and so forth, which may be fitted between the arrester and the atmosphere.

8.2.5 Devices that are provided with a heating arrangement shall pass the required tests at the heated temperature.

8.2.6 After all tests are completed, the device shall be disassembled and examined, and no part of the device shall be damaged or show permanent deformation.

9. Test Procedures for Flame Arresters

9.1 Media/Air Mixtures:

9.1.1 For vapors from flammable or combustible liquids with a MESG greater than or equal to 0.9 mm, technical grade hexane or gasoline vapors shall be used for all tests in this section, except technical grade propane may be used for the flashback test in 9.2. For vapors with a MESG less than 0.9 mm, the specific vapor (or alternatively, a media with a MESG less than or equal to the MESG of the vapor) shall be used as the test medium in all Section 9 tests.

9.1.2 Hexane, propane, gasoline, and chemical vapors shall be mixed with air to form the most easily ignitable mixture. 7

9.2 Flashback Test:

9.2.1 A flashback test shall be carried out as follows:

9.2.1.1 The test rig shall consist of an apparatus producing an explosive mixture, a small tank with a diaphragm, a prototype of the flame arrester, a plastic bag, and a firing source in three positions (see Fig. 1). 9

9.2.1.2 The tank, flame arrester assembly, and plastic bag enveloping the prototype flame arrester shall be filled so that this volume contains the most easily ignitable vapor/air mixture. 7 The concentration of the mixture should be verified by appropriate testing of the gas composition in the plastic bag. Three ignition sources shall be installed along the axis of the bag, one close to the flame arrester, another as far away as possible therefrom, and the third at the midpoint between these two. These three sources shall be fired in succession, one during each of the three tests. Flame passage shall not occur during this test.

9.2.1.3 If flame passage occurs, the tank diaphragm will burst and this will be audible and visible to the operator by the emission of a flame. Flame, heat, and pressure sensors may be used as an alternative to a bursting diaphragm.

7 See IEC Publication 79-1.

8 The dimensions of the plastic bag are dependent on those of the flame arrester. The plastic bag may have a circumference of 2 m, a length of 2.5 m, and a wall thickness of 0.05 m.

9 To prevent remnants of the plastic bag from falling back onto the flame arrester being tested after ignition of the fuel/air mixture, it may be useful to mount a coarse wire frame across the flame arrester within the plastic bag. The frame should be constructed so as not to interfere with the test result.
9.3 Endurance Burn Test:

9.3.1 An endurance burning test shall be carried out as follows:

9.3.1.1 The test rig referred to in 9.2.1.1 may be used, without the plastic bag. The flame arrester shall be so installed that the mixture emission is vertical. The mixture shall be ignited in this position.

9.3.1.2 Endurance burning shall be achieved by using the most easily ignitable test vapor/air mixture with the aid of a pilot flame or a spark igniter at the outlet. By varying the proportions of the flammable mixture and the flow rate, the arrester shall be heated until the highest obtainable temperature on the cargo tank side of the arrester is reached. The highest attainable temperature may be considered to have been reached when the rate of temperature increase does not exceed 0.5°C per minute over a 10-min period. This temperature shall be maintained for a period of 10 min, after which the flow shall be stopped and the conditions observed. If difficulty arises in establishing the highest attainable temperature, the following criteria shall apply. When the temperature appears to be approaching the maximum temperature, using the most severe conditions of flammable mixtures and flow rate, but increases at a rate in excess of 0.5°C per minute over a 10-min period, endurance burning shall be continued for a period of 2 h, after which the flow shall be stopped and the conditions observed. Flame passage shall not occur during this test.

10. Inspection

10.1 The manufacturer shall afford the purchaser’s inspector all reasonable facilities necessary to ensure that the material is being furnished in accordance with this specification. All examinations and inspections shall be made at the place of manufacture, unless otherwise agreed upon.

10.2 Each finished flame arrester shall be visually and dimensionally checked to ensure that the device corresponds to this specification, is certified in accordance with Section 11, and is marked in accordance with Section 12. Special attention shall be given to checking the proper fit-up of joints (see 7.5 and 7.6).

11. Certification

11.1 Manufacturer’s certification that a flame arrester has been constructed in accordance with this specification shall be provided in an instruction manual. The manual shall include the following, as applicable:

11.1.1 Installation instructions and a description of all configurations tested (see 8.2.4.1 and 8.2.4.2). Installation instructions to include manufacturer’s recommended limitations based on all configurations tested.

11.1.2 Operating instructions.

11.1.3 Maintenance requirements.

11.1.3.1 Instructions on how to determine when flame arrester cleaning is required and the method of cleaning.

11.1.4 Copy of the test report (see 8.1.1).

11.1.5 Flow test data, including flow rates under both positive and negative pressures, operating sensitivity, flow resistance, and velocity.

11.1.6 The ambient air temperature range over which the device will effectively prevent the passage of flame.

NOTE 2—Other factors such as condensation and freezing of vapors should be evaluated at the time of equipment specification.

12. Product Marking

12.1 Each flame arrester shall be permanently marked indicating:

12.1.1 Manufacturer’s name or trademark,

12.1.2 Style, type, model, or other manufacturer’s designation for the flame arrester,

12.1.3 Size of the inlet and outlet,

12.1.4 Type of device (Type I or II),

12.1.5 Direction of flow through the flame arrester,

12.1.6 Test laboratory and report number,

12.1.7 Lowest MESG of gases for which the flame arrester is suitable,

12.1.8 Ambient air operating temperature range, and

12.1.9 Specification F 1273.

13. Quality Assurance

13.1 Flame arresters shall be designed, manufactured, and tested in a manner that ensures they meet the characteristics of the unit tested in accordance with this specification.

13.2 The flame arrester manufacturer shall maintain the quality of the flame arresters that are designed, tested, and marked in accordance with this specification. At no time shall a flame arrester be sold with Specification F 1273 that does not meet the requirements herein.

14. Keywords

14.1 combustible liquid; flame arrester; flammable liquid; marine technology; ships; tank vent; tank vent flame arrester
INTRODUCTION

This guide provides information on symbols for lifesaving appliances and arrangements required by Chapter III/9.2.3 of the 1983 Amendments to the 1974 Safety of Life at Sea Convention (SOLAS). Though this requirement applies only to ships that have either a SOLAS Passenger Ship Safety Certificate or SOLAS Cargo Ship Safety Equipment Certificate, it is recommended that all vessels or facilities engaged in waterborne operations seriously consider the use of this guide.

1. Scope

1.1 This guide sets forth those symbols to be used to identify the location and operation of lifesaving equipment related to evacuation of personnel in the marine environment.

1.2 The symbols depicted should be used whenever graphic representation could assist personnel in locating their emergency stations and equipment and in the operation of such equipment.

1.3 Posters or signs depicting these symbols should be placed in conspicuous locations in the vicinity of survival craft, their launching controls, or other lifesaving equipment.

1.4 The values stated in SI units are to be regarded as standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 Safety of Life at Sea Convention:2
SOLAS 74 International Convention for the Safety of Life at Sea

3. Significance and Use

3.1 The symbols depicted represent the following:
3.1.1 Equipment required during evacuation or rescue,
3.1.2 Location of muster stations in preparation for evacuation or rescue, or
3.1.3 The sequence of events for operation of survival craft.
3.2 Where station numbers are used with another symbol, they should be abutted to the right hand side of the other symbol.

3.3 Arrows may be used with any other symbol and, where feasible, should point in the direction of the equipment or station by being abutted to the symbol on the edge toward which the arrow is pointing.

3.4 Symbols that indicate station or equipment location should be in white on a green background (see Figs. 1 and 2).

3.5 Symbols that specify the operating sequence of survival craft should be in white on a blue background (see Fig. 3).

3.6 Symbols used as legends in station bills, lifesaving equipment arrangement plans or drawings, or other posters, need not meet the dimensions specified in 3.7.

3.7 Symbols used as markers to indicate the location of stations or equipment should be sized in accordance with 3.7.1 or 3.7.2.

3.7.1 Station number symbol dimensions should be a minimum of 150 mm in height by 75 mm in width (6 by 3 in.).

3.7.1.1 Station number symbol dimensions of 600 by 300 mm (24 by 12 in.) should be used for greater prominence with the larger muster station symbol specified in 3.7.2.1.

3.7.2 Other symbol dimensions should be a minimum of 150 by 150 mm (6 by 6 in.), except:

3.7.2.1 A muster station symbol with dimensions of 600 by 600 mm (24 by 24 in.) may be used in conjunction with the larger station number symbol specified in 3.7.1.1.

3.8 Symbols depicted in Figs. 1 and 2 should represent the survival craft that is actually provided.

4. Illustration of Symbols

4.1 Fig. 1 and Fig. 2 (a through w) are symbols indicating location of emergency equipment and muster and embarkation stations.

4.2 Fig. 3 (a through j) represent the general sequence of events that can be expected during the launching of survival craft. The symbols should reflect the launching procedure recommended by the survival craft or system manufacturer.
5. Keywords

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for
Flexible, Expansion-Type Ball Joints for Marine
Applications

This standard is issued under the fixed designation F 1298; the number immediately following the designation indicates the year of
original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A
superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design, manufacture, and
testing of ball joints utilized for accommodating thermal
expansion and contraction, or mechanical movement of a
pipeline carrying fluid. The ball joints are intended for use in
systems operating above 0°F (18°C).

1.2 The following precautionary caveat pertains only to the
test methods portion, Section 7, of this specification: This
standard does not purport to address all of the safety concerns,
if any, associated with its use. It is the responsibility of the user
of this standard to establish appropriate safety and health
practices and determine the applicability of regulatory limita-
tions prior to use.

2. Referenced Documents

2.1 ASTM Standards:
A 395 Specification for Ferritic Ductile Iron Pressure-
Retaining Castings for Use at Elevated Temperatures
F 722 Specification for Welded Joints for Shipboard Piping
Systems
2.2 ANSI Standard:
B 31.1 Power Piping
2.3 American Society of Mechanical Engineers,
ASME Boiler and Pressure Vessel Code, Section VIII,
Division 1, Pressure Vessels Section IX, Welding and
Brazing Requirements

3. Ordering Information

3.1 Each purchase order or inquiry for ball joints to this
specification shall include the following as applicable:
3.1.1 Title, number, and latest revision of this specification,
3.1.2 Manufacturer’s part number or ball-joint type informa-
tion,
3.1.3 Materials for ball joint and seals, if other than to this
specification,
3.1.4 Service conditions,
3.1.4.1 Minimum and maximum operating temperature
(°F),
3.1.4.2 Maximum operating pressure (psig),
3.1.5 Fluid media (internal),
3.1.6 Atmosphere or media (external),
3.1.7 ANSI pressure class, facing and drilling of flanged
ends, and pipe schedule or wall thickness of ends for weld end
joints,
3.1.8 Special end connections as defined by the purchaser,
3.1.9 Ball sphere or other special coatings, if required,
3.1.10 Qualification test report, if required,
3.1.11 Drawing requirements; for example, envelope drawing
sufficiently detailed to describe the ball joint to be supplied,
and
3.1.12 Other tests to satisfy customer requirements.

4. Materials and Manufacture

4.1 All pressure retaining components shall be fabricated
from wrought or cast steel. Ductile iron complying with
Specification A 395 may be used for the ball joint retaining
ring in services not above 350 psig (2.41 N/mm²) or 450°F
(232°C). Steel shall comply with one of the materials listed in
Section VIII, Division 1, of the ASME Code, or ANSI B 31.1.
4.2 Bolting material shall be in accordance with ANSI
B 31.1.
4.3 Ball spheres shall be coated in accordance with the
manufacturer’s standard practice or as specified by the custom-
er’s specification (see 3.1.9).
4.4 Corrosion shall be considered in the design as set forth
in UG-25 of the ASME Code, Section VIII, Division 1.
4.5 Seals and packing material shall be suitable for the
service intended. This includes being adequate for the pressure
and temperature rating and having sufficient resistance to
attack by the fluid media and atmosphere specified in Section
3.
4.6 Welding procedure qualification, welder performance qualification, and welding materials shall be in accordance with ANSI B 31.1 and Section IX of the ASME Code. Brazing or soldering shall not be used.

5. Other Requirements

5.1 Design:
5.1.1 Ball joints shall be designed to conform to applicable sections of the latest edition of ANSI B 31.1.
5.1.2 Packing—The design for containment of leakage shall be of the manufacturer’s standard design and be qualified by prototype testing of 7.1.

5.2 Pressure and Temperature Rating:
5.2.1 The maximum allowable working pressure (MAWP) and temperature rating for ball joints conforming to this specification shall be established by at least one of the following methods:
5.2.1.1 Proof test in accordance with the requirements prescribed in paragraph UG-101 of Section VIII, Division 1, of the ASME Code. If burst type tests as outlined in paragraph UG-101(m) are used, it is not necessary to rupture the component which the component was subjected without rupture. Components that have been subjected to a hydrostatic proof test shall not be offered for sale.
5.2.1.2 Design calculations in accordance with the requirements prescribed in Section VIII, Division 1, of the ASME Code.
5.2.2 Each ball joint bolting or retainer nut shall be adjusted for proper torque.
5.3 Inlet and outlet connections consisting of welded flanges and fittings shall be in accordance with Specification F 722. When radiography is required (see 8.2), all welds shall be butt welds for Class I piping as required by Specification F 722, except for fillet welds, all welds shall be full penetration welds extending through the entire thickness of the shell.

5.4 Where welded construction is used for the fabrication of pressure containing parts, welded joint design details shall be in accordance with Section VIII, Division 1, of the ASME Code and Specification F 722. Except for fillet welds, all welds shall be visually examined in accordance with the requirements prescribed in Section VIII, Division 1, of the ASME Code.

5.5 Inlet and outlet connections consisting of welded flanges and fittings shall be in accordance with Specification F 722. When radiography is required (see 8.2), all welds shall be butt welds for Class I piping as required by Specification F 722, except for fillet welds, all welds shall be full penetration welds extending through the entire thickness of the shell.

5.6 Threaded pipe connections shall be limited to the following services:

<table>
<thead>
<tr>
<th>Size</th>
<th>Pressure (psi)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3/4 in.</td>
<td>1500 psi</td>
</tr>
<tr>
<td>1 in.</td>
<td>1200 psi</td>
</tr>
<tr>
<td>2 in.</td>
<td>600 psi</td>
</tr>
<tr>
<td>3 in.</td>
<td>400 psi</td>
</tr>
</tbody>
</table>

5.7 Threaded pipe joints above 2 in. (50 mm) NPS shall not be used in systems that require radiographic examination (see 8.2.2).

6. Workmanship, Finish, and Appearance

6.1 Cleaning—The internal and external surfaces of the ball joint shall be cleaned of dirt and other foreign material using a suitable cleaner.

6.2 Surface Preservation—Unless otherwise specified by the purchaser, the ball joint shall be coated in accordance with the manufacturer’s standard practice.

7. Test Methods or Analytical Methods

7.1 Qualification Tests:
7.1.1 A ball joint of each standard design shall be certified as having undergone the following qualification tests. The ball joint shall not show leakage of the test fluid under the conditions of pressurization stipulated in each test.
7.1.1.1 Flex Cycle Test—The ball joint shall be subjected to 8000 flex cycles at MAWP and maximum rated temperature over the rated flex angle. Each flex cycle shall consist of rotating the ball joint from maximum flex angle on one side through $0^\circ$ to maximum flex angle on the other side and return to the original position. The flex cycle rate shall not exceed 4 cpm. At the end of 8000 cycles, MAWP shall be held for at least $\frac{1}{2}$ h.
7.1.1.2 Thermal Cycling—Ball joints rated above 200°F shall be subjected to 100 saturated steam pressure cycles from atmospheric pressure to MAWP and back to atmospheric pressure. Each cycle shall permit the joint to reach saturated steam temperature at MAWP and then cool to ambient temperature. At the end of test, MAWP shall be held for $\frac{1}{2}$ h at saturated steam temperature.

7.2 Production Tests:
7.2.1 Each ball joint shall be subjected to a hydrostatic test conducted at 1½ times the 100°F (38°C) rated maximum allowable working pressure of the ball joint. The test shall be made with water or other fluid having a maximum viscosity of 40 SSU at 125°F (52°C). Minimum duration of test shall be 15 s for ball joints less than 2 in. (50 mm) nominal pipe size, 1 min for ball joints 2½ in. (63.5 mm) through 8 in. (203 mm), and 3 min for larger sizes. The purpose of this test is to detect leaks and structural imperfections. No visible leakage is permitted.

7.2.1.1 The pressure-containing boundary components of each ball joint may be individually hydrostatically tested provided that an assembled prototype has been subjected to a hydrostatic test as outlined in 7.2.1.
7.2.1.2 The test arrangement shall be air-free prior to pressurization.
7.2.2 Ball joints of 2 in. (50 mm) NPS and smaller with other than flanged connections may, at the option of the manufacturer, be air tested to the lesser of 1.2 times the MAWP or 80 psig (0.55 N/m²). The minimum duration of the test shall be 15 s. Visually detectable leakage through the pressure-retaining walls is not acceptable.

7.2.2.1 If this option is exercised, the manufacturer shall be able to certify that a prototype from each production lot of the same size ball joint was subjected to a hydrostatic test in accordance with 7.2.2.1.

8. Inspection

8.1 Each finished ball joint shall be visually examined and dimensionally checked to ensure it corresponds to this specification.
8.2 Nondestructive Examination of Welds:
8.2.1 All welds shall be visually examined in accordance with ANSI B 31.1.
8.2.2 Welded inlet and outlet connections that are equal to or greater than 4 in. nominal diameter or greater than 0.375 in. nominal wall thickness that are in the following services shall be 100% radiographically examined:

<table>
<thead>
<tr>
<th>Service</th>
<th>Pressure, psig (N/mm²)</th>
<th>Temperature, °F (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fuel oil</td>
<td>above 150 (1)</td>
<td>or above 150 (65)</td>
</tr>
<tr>
<td>Steam</td>
<td>above 150 (1)</td>
<td>or above 650 (343)</td>
</tr>
<tr>
<td>Flammable cargo</td>
<td>above 225 (1.55)</td>
<td>or above 150 (65)</td>
</tr>
<tr>
<td>Water</td>
<td>above 225 (1.55)</td>
<td>or above 350 (194)</td>
</tr>
</tbody>
</table>

Standard Practice for Installation Procedures for Fitting Chocks to Marine Machinery Foundations

This standard is issued under the fixed designation F 1309; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the acceptable methods of fitting chocks to marine machinery foundations.

1.2 The values stated in SI units shall be regarded as standard. The values in parentheses are for information only.

1.3 This standard does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

2.2 Other Documents:

   American Bureau of Shipping Rules for Building and Classing Steel Vessels
   American Welding Society Publication, AWS D1.1 Structural Welding Code

3. Significance and Use

3.1 This practice provides the three principal methods of fitting chocks to marine machinery foundations to ensure that the machinery is free of vibration and perfectly aligned after installation.

3.1.1 The three principal methods of installing chocks described herein are as follows:

   3.1.1.1 Type A—Epoxy-based resin, nonshrinking Chockfast Orange PR 610 TCF by Philadelphia Resin Corp., or equal, and
   3.1.1.2 Type B—Two-piece wedge chocks.
   3.1.1.3 Type C—Solid, one-piece fitted chocks.

4. Procedure

4.1 General Requirements for Types A, B, and C Chocking Systems:

4.1.1 Machining:

4.1.1.1 Type A chocks, machinery bedplates, foundation plates, and bolts do not require finish machining if the chocks are not designed to be removed. Unless specified otherwise, Types B and C chock, bolts/studs, machinery bedplate, foundation plates, and fitted holes need to be finished machined and fitted.

4.1.1.2 Surfaces in way of the chock areas on the machinery bedplate and the foundation plate may be machined before installation or while the ship is not waterborne, or both.

4.1.1.3 Unless otherwise specified, all finished surfaces shall be finished to a maximum of 0.003-mm roughness height average (RHA).

4.1.1.4 Finished areas on the machinery bedplate and the foundation plate in way of the chocks shall be sufficiently greater in size than the chock to prevent interference from the unfinished area with the chock during installation.

4.1.1.5 Spotface hole edge radius shall be such that there will not be any interference between it and the bolt head-to-shank radius. The spotface area shall be sufficiently greater in area than that of the bolt head or nut so as not to cause any interference when tightening or with the tooling used. The spotface surfaces shall be perpendicular to the finished fitted hole centerline.

4.1.2 Installation:

4.1.2.1 The ship must be waterborne and fairly well completed before final alignment is accomplished. Ship shall be trimmed as close to the even keel position as practicable. The same trim position shall be maintained throughout the alignment procedure. No heavyweight shall be moved, loaded, or unloaded during alignment; ramps for Ro-Ros shall not be lowered or hoisted.
4.1.2.2 Final machining of the fitted or bearing areas of the machinery bedplate to chock to foundation plate and the mating areas of the fitted portion of the bolt/stud shank and to the hole wall shall be a minimum of 85% uniformly distributed around the mating area. A light coat of Prussian blue shall be used to check the contact areas.

4.1.2.3 Machinery shall be aligned using a sufficient number of jackscrews, shims, and wedges to accommodate adequate up-down, port-starboard, and fore-aft movement without distorting the machinery bedplate or foundation plate and, once aligned, be able to hold that alignment firmly during the final chock installation and bolt-fitting phase.

4.1.2.4 A sufficient number of fitted bolts and chocks shall be installed to maintain the alignment and prevent any relative movement between the machinery and the foundation as a result of vibration and sea state inputs. Number and position of fitted bolts shall comply with the engine manufacturer’s requirements, if any.

4.1.2.5 Bolts shall be installed from the bottom up unless surrounding interferences dictate otherwise.

4.1.2.6 The length of the fitted portion of the bolt/stud shank shall be 95% of the combined thickness between spotfaces of the machinery bedplate, chock, and foundation plate.

4.1.2.7 Final reaming of the fitted bolt holes or machining of the bolt shank shall occur after final alignment.

4.1.2.8 Final torquing of each bolt/nut/stub assembly shall be of sufficient torque to preload the nonfitted portions of the bolt/nut/stub enough to prevent loosening as a result of vibrations, operations, hull, and sea state inputs.

4.1.2.9 Welding shall be performed in accordance with American Bureau of Shipping or the American Welding Society, Structural Code AWS D1.1.

4.1.3 Testing (If Specified):

4.1.3.1 Steel tension tests shall be made in accordance with Test Methods and Definitions A 370.

4.1.3.2 Compression yield and modulus of elasticity tests shall be made in accordance with Test Method D 695.

4.1.3.3 The tensile ultimate test shall be made in accordance with Test Method D 638.

4.1.3.4 The shear ultimate test, the heat distorting temperature test, and the shock resistance test shall be made in accordance with Test Method D 648.

4.2 Type A—Epoxy-based resins are pourable compounds that are poured into properly contained and vented volumes and cure at normal ambient temperatures without shrinkage to form a durable solid.

4.2.1 Provision for Future Machinery Removal—To prevent adhesion of chocks to adjoining surfaces and facilitate future removal of machinery, spray an aerosol release agent on all contact surfaces. This precaution allows these chocks to be removed in a similar manner to steel chocks.

4.2.2 Applicable Techniques:

4.2.2.1 Position dams to retain the compound during pouring and curing without distortion. Damming materials may be expanded plastic, foam rubber stripping and sheet metal, or light gage flat bar. (See Fig. 1.)

4.2.2.2 Follow resin manufacturer’s instructions including the relative design parameters on loading, temperature, allowable thickness, additional design, installation, bolt tension, and inspection.

4.2.3 Foundation Bolts—Install hold-down bolts before pouring of resin. Tension (torque) bolts only after resin manufacturer’s recommended cure time.

4.3 Type B, Two-Piece Wedge Chock—The two-piece wedges are drop-forged, medium steel or machined from steel plate of equal strength or of other materials as specified.

4.3.1 Applicable Techniques—Fig. 2 indicates the configuration of Type C chocks to the machinery bedplate and the foundation plate.

4.3.1.1 The taper on the sloped faces of each half of the chock must not exceed a rise of one over a run of four.

4.3.1.2 Align machinery in place as described in 4.1 and install the lower half of the tapered chock in place with the thicker end in first from the place installation. Ensure it does not move by tack welding. Do not allow distortions or separations.

4.3.1.3 Spotface the upper surface of the machinery bedplate where the finish has not been indicated.

4.3.2 Fitting of Chocks and Bolts—Fig. 3 indicates the fitting of Type B chocks in way of the bedplates and foundation pieces.

4.3.3 Bearing Area—To obtain the 85% bearing area, either measure the spacing between the machine bedplate and the foundation plate at the four corners in way of the proposed chock location and machine the chocks as a unit to fit or, if the lower half of the taper chock is in place, take the same measurement between it and the machinery bedplate in way of the lower half. Machine the upper half to fit and verify the adequacy of the contact area.

4.3.4 Drill holes in the bottom chock piece and foundation plate, either with machinery unit in place or by the marking of holes and lifting the unit clear. Spotface the bottom side of the foundation plate in way of bolt heads.

4.3.5 Fitted Bolts—Fit the bolts/studs to the holes by measuring diameters at 90° to each other in approximately four planes equally spaced through the hole and machine the bolt/stud shank to fit or ream the hole to fit the bolt. Torque the nuts to the proscribed torque.

4.3.6 Excess Length of Chock—Determine the length (with an extra allowance for fitting), and the thickness of the topmost piece of the permanent chock assembly (wedge) at installation. Drill the wedge only after it has been finally fitted in place. Face off the excess length flush with plate edges, and preserve the relative positions of chock parts by tackwelding. For the restrictions and size of the taper see Fig. 3.

4.4 Type C, Solid, One-Piece Fitted Chocks—The chocks are medium steel machined from plate steel consistent with the machinery bedplate and foundation plate and the loads imposed or of other materials as specified.

4.4.1 Applicable Techniques—Fig. 2 indicates the configuration of Type C chocks to the machinery bedplate and the foundation plate.

4.4.2 Align machinery in place as described in 4.1. Do not allow distortions or separations.
4.4.3 *Bearing Area*—To obtain the 85% bearing area, measure the spacing between the machinery bedplate and the foundation plate, measure the gap at the four corners in way of the proposed chock location as indicated in Fig. 2, machine the chock to fit, and verify the adequacy of the bearing area.

4.4.4 *Fitted Bolts*—Fit the bolts/studs to the holes by measuring diameters at 90° to each other in approximately four planes equally spaced through the hole and machine the bolt/stub shank to fit or ream the hole to fit the bolt/stud. Torque the nuts to the proscribed torque.

Standard Specification for Large–Diameter Fabricated Carbon Steel Flanges

This standard is issued under the fixed designation F 1311; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification provides design and construction criteria for large diameter flanges sizes 14 to 144 NPS, for use in high temperature (1000°F), low pressure service (25 psig), such as internal combustion engine exhaust and forced ventilation systems.

1.2 Values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 ASTM Standards:
- A 36/A 36M Specification for Carbon Structural Steel
- F 1155 Practice for Selection and Application of Piping System Materials

2.2 American Water Works Association:
- AWWA C 207 Steel Pipe Flanges for Waterwork Service

2.3 Other Documents:

- ASME Boiler and Pressure Vessel Code, Section IX, Welding Qualifications

3. Classification

3.1 Type I—Plate flanges, for sizes 14 in. inside diameter up to and including 144 in. inside diameter (see Fig. 1).

3.2 Type II—Rolled angle flanges, for sizes 14 in. up to and including 108 in. inside diameter (see Fig. 1).

4. Ordering Information

4.1 Flanges ordered under this specification shall include the following:
- ASTM designation, title, number, and date of this specification,
- Type and material,
shall apply on flanges of 22 in. nominal pipe size and above.  
identical for both Type I and Type II flanges.

5. Dimensions and Tolerances

5.1 Dimensions—Dimensions shall be in accordance with Table 1.

5.2 Tolerances:
5.2.1 Plus or minus ¼ in. on outside and inside diameters shall apply on flanges of 22 in. nominal pipe size and above. The tolerance for flanges for 20 in. nominal size and below shall be ±⅛ in.
5.2.2 Plus or minus ⅛ in. on bolting circle.

6. Drilling

6.1 Number of holes, hole diameter, and bolt circle are identical for both Type I and Type II flanges.
6.2 Bolt holes shall be equally spaced on the bolt circle.
6.3 Bolt holes provide for ½ in. diameter clearance on bolts.
6.4 Drilling of flanges shall be in accordance with Table 1.

7. Workmanship, Finish, and Appearance

7.1 Flanges manufactured under this specification shall be free of all sharp edges, burrs, projections, weld spatter, and other defects that might be hazardous to personnel or equipment, or both.
7.2 Welding shall be in accordance with the American Bureau of Shipping Rules for Building and Classing of Steel Vessels, ABS Grade A, American Welding Society Publications D 1.1, or ASME Code Section IX.
7.3 Flange faces shall be smooth and free of projections or indentations that would prevent effective gasket seals.
7.4 Flanges when completed shall have no distortion, roundness, or flatness exceeding a tolerance of ±⅛ in.
7.5 The surface finish shall be a minimum of 500 μin. to ensure proper sealing surface for the gasket.
7.6 The material to be used for this specification shall be in accordance with Specification A 36/A 36M, unless prolonged high temperatures will be required; in that case ABS Grade A steel shall be specified in Section 4. For further guidance for selection of materials, see Practice F 1155 and CFR 56.30-10(b)(5).

F 1311 – 90 (2001)
8. Rejection and Rehearing

8.1 Flanges that fail to conform to the requirements of this specification may be rejected. Rejection may be reported to the producer or the supplier promptly in writing. In case of dissatisfaction with the damaged items, the producer or the supplier may make claim for a rehearing.

9. Certification

9.1 When specified in the purchase order or the contract, the purchaser shall be furnished with certification that samples representing the flanges have been inspected to meet the requirements of this specification. When specified in the purchase order or contract, a report of the results shall be furnished.

10. Packaging and Package Marking

10.1 Flanges shall be marked on the edge of each flange showing the purchase order number, ASTM designation number, material and type, size, and name of manufacturer.

10.2 The flanges shall be packaged in a manner acceptable for shipment by common carrier.

11. Keywords

11.1 carbon steel; flanges; large-diameter flanges; low-pressure service flanges; marine technology; ships
Standard Specification for
Brick, Insulating, High Temperature, Fire Clay¹

1. Scope
1.1 This specification covers one type of thermal insulating brick for use as backup insulation for refractory furnace linings of boiler furnaces.
1.2 The values stated in inch-pound units are to be regarded as standard. The SI units in parentheses are for information purposes only and may be approximate.

2. Referenced Documents
2.1 ASTM Standards:
C 93 Test Methods for Cold Crushing Strength and Modulus of Rupture of Insulating Firebrick²
C 134 Test Methods for Size, Dimensional Measurements, and Bulk Density of Refractory Brick and Insulating Firebrick³
C 210 Test Method for Reheat Change of Insulating Firebrick³

2.2 Federal Specifications:
PPP-B-601 Boxes, Wood, Cleated-Plywood⁴
PPP-B-621 Boxes, Wood, Nailed and Lock Corner⁴
PPP-B-636 Box, Fireboard⁴

2.3 Military Specifications:
MIL-L-10547 Liners, Case, and Sheet, Overwrap; Vapor-proof or Waterproof, Flexible⁴

2.4 Military Standards:
MIL-STD-105 Sampling Procedures and Tables for Inspection by Attributes⁴
MIL-STD-129 Marking for Shipment and Storage⁴

¹ This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.
³ Annual Book of ASTM Standards, Vol 15.01.
⁴ Available from Standardization Documents, Order Desk, Bldg. 4, Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

3. Ordering Information
3.1 Orders for material under this specification shall include the following information as necessary to describe the material adequately:
3.1.1 ASTM designation and year of issue,
3.1.2 Dimensions required (see 6.1), and
3.1.3 Optional requirements, if any (see S1 through S3).

4. Material and Manufacture
4.1 Bricks shall be composed of heat-resistant materials which have been burned or fired to produce the desired density, strength, and structure.

5. Physical and Mechanical Properties
5.1 The average bulk density shall not exceed 45.0 lb/ft³ (720 kg/m³) (see 9.2).
5.2 The modulus of rupture shall average not less than 100 psi (700 kPa) (see 9.3).
5.3 Bricks shall show an average reheat change of not more than 1 % when heated at 2450°F (1343°C) (see 9.4).

6. Dimensions and Permissible Variations
6.1 Insulating brick shall be furnished in the dimensions specified (see 3.1.2). Standard size brick shall be 9 by 4½ by 2½ in. (229 by 114 by 64 mm), 9 by 4½ by 2 in. (229 by 114 by 51 mm), or 9 by 4½ by 1¼ in. (229 by 114 by 32 mm), as specified.
6.2 Standard size brick shall not vary more than ±½ in. (12 mm) from specified dimensions of 2 in. (51 mm) or greater, nor more than ±¼ in. (1 mm) from specified dimensions less than 2 in. (see 9.2).
6.3 For special shapes, no dimension shall vary more than ±1‰ in. (2 mm) from the dimensions specified (see 9.2).
7. Workmanship, Finish, and Appearance

7.1 Bricks shall be of homogeneous structure, free from cracks, laminations, segregations, void defects, or soft centers. All corners and edges shall be sufficiently strong to prevent excessive crumbling or chipping when handled or shipped.

8. Sampling

8.1 For purposes of sampling, an inspection lot for examination and tests shall consist of all material of the same size and shape offered for delivery at one time.

8.2 The sample unit for the tests of Section 9 shall be one brick.

8.3 The sample size (the number of sample units) for the tests of Section 9 shall be as specified in Table 1.

9. Test Methods

9.1 Testing of the End Item—The end item shall be tested for the applicable characteristics as shown on Table 1 from each lot presented for examination for each size and shape of brick.

9.2 Dimensions and Bulk Density—Dimensions and bulk density shall be determined in accordance with the test method specified in Test Methods C 134.

9.3 Modulus of Rupture—The modulus of rupture shall be determined in accordance with the test method specified in Test Methods C 93.

9.4 Reheat Change—The reheat change shall be determined in accordance with Test Method C 210, except that the test specimens shall be maintained at a temperature of 2550°F (1343°C) for 24 h.

10. Inspection

10.1 Unless otherwise specified in the contract or purchase order, the supplier is responsible for the performance of all inspection requirements specified herein. Except as otherwise specified, the supplier may use his own or any other facilities suitable for the performance of the inspection requirements specified herein, unless disapproved by the purchaser. The purchaser reserves the right to perform any of the inspections set forth in the specification where such inspections are deemed necessary to ensure that supplies and services conform to prescribed requirements.

11. Product Marking

11.1 Bricks shall be marked with the manufacturer’s name or trademark by suitable indentation or stamping.

12. Packaging

12.1 Bricks shall be packed in containers which will ensure acceptance by common carrier and safe delivery to destination at the lowest applicable rate. Containers shall comply with commercial carrier regulations.

13. Keywords

13.1 brick; insulating brick; fire clay

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified in the contract or purchase order (see 3.1.3).

S1. Referenced Documents

S1.1 The following documents shall apply only when one or more of the requirements of S2 or S3 are specified in the contract or purchase order (see 3.1.3): Federal Specifications PPP-B-601, PPP-B-621, and PPP-B-636; Military Specification MIL-L-10547; and Military Standards MIL-STD-105, MIL-STD-129, and MIL-STD-147.

S2. Special Government Requirements

S2.1 Examinations and Test Requirements:

S2.1.1 Examination of end item for defects in appearance, workmanship, and dimensions. An examination shall be made in accordance with Tables S1-S4 to determine that the appearance, workmanship, and dimensions of the end item comply with the requirements of this specification.

S2.1.1 The sample unit shall be one brick.
S2.1.2 Examination of preparation for delivery. An examination shall be made in accordance with Table S2 and Table S4 to determine that the packing and markings comply with the requirements of Table S3 of this specification.
S2.1.2.1 The sample unit shall be one shipping container, fully packed, selected just before the closing operation.
S2.1.3 Examination of palletized unit loads, as applicable. Unless palletization is not required (see S3.3), an examination in accordance with Table S3 and Table S4 shall be made to determine that palletized unit loads comply with requirements of MIL-STD-147.
S2.1.3.1 The sample unit shall be one palletized load.
S2.1.4 For the test specified in 9.2, the sample size for examination of dimensions shall be governed by S2.1.2.1.
S2.2 The inspection levels for determining the sample size and the acceptable quality levels (AQLs), expressed in defects per 100 units, shall be as specified in Table S4, in accordance with MIL-STD-105.

### S3. Preparation for Delivery

S3.1 Level A—When level A is specified (see 3.1.3), bricks shall be packed in snug-fitting, wood-cleated plywood, nailed wood, or fiberboard boxes conforming to PPP-B-601 (overseas type), or PPP-B-621 (Class 2), or PPP-B-636 (V3c or V3s), respectively. Plywood and nailed wood boxes shall be lined with sealed case liners conforming to MIL-L-10547. Boxes shall be closed and reinforced in accordance with the appendix to the applicable box specification, but wire strapping shall not be used with fiberboard boxes. Crimp-type connectors shall be used with metallic or nonmetallic strapping.
S3.1.1 Each box shall contain not more than the following: 25 Bricks—9 by 4 1/2 by 2 in. (229 by 114 by 51 mm), 40 Bricks—9 by 2 1/2 by 2 1/2 in. (229 by 114 by 64 mm), or 50 Bricks—9 by 1 3/4 by 2 1/2 in. (229 by 114 by 64 mm).
S3.2 Level B—When Level B is specified (see 3.1.3), bricks, in unit quantities specified in S3.1.1, shall be packed in snug-fitting fiberboard boxes conforming to PPP-B-636 (domestic class, grade 200). Boxes shall be closed by Method II and reinforced by use of filament tape, flat steel, or nonmetallic straps in accordance with the appendix to PPP-B-636. Crimp-type connectors shall be used with metallic or nonmetallic strapping.
S3.3 Palletizing—Unless otherwise specified (see 3.1.3), packed brick shall be palletized in accordance with MIL-STD-147. Palletized loads shall be provided with fiberboard caps.
S3.4 Marking—In addition to any special marking required by the contract or purchase order, shipping containers and palletized unit loads shall be marked in accordance with MIL-STD-129. Shipping containers shall be marked as follows: STORE IN DRY PLACE.
Standard Guide for Conducting a Stability Test (Lightweight Survey and Inclining Experiment) to Determine the Light Ship Displacement and Centers of Gravity of a Vessel

This standard is issued under the fixed designation F 1321; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reaffirmation. A superscript epsilon (e) indicates an editorial change since the last revision or reaffirmation.

INTRODUCTION

This guide provides the marine industry with a basic understanding of the various aspects of a stability test. It contains procedures for conducting a stability test to ensure that valid results are obtained with maximum precision at a minimal cost to owners, shipyards, and the government. This guide is not intended to instruct a person in the actual calculation of the light ship displacement and centers of gravity, but rather to be a guide to the necessary procedures to be followed to gather accurate data for use in the calculation of the light ship characteristics. A complete understanding of the correct procedures used to perform a stability test is imperative to ensure that the test is conducted properly and so that results can be examined for accuracy as the inclining experiment is conducted. It is recommended that these procedures be used on all vessels and marine craft.

1. Scope

1.1 This guide covers the determination of a vessel’s light ship characteristics. The stability test can be considered to be two separate tasks; the lightweight survey and the inclining experiment. The stability test is required for most vessels upon their completion and after major conversions. It is normally conducted inshore in calm weather conditions and usually requires the vessel be taken out of service to prepare for and conduct the stability test. The three light ship characteristics determined from the stability test for conventional (symmetrical) ships are displacement (displ), longitudinal center of gravity (LCG), and the vertical center of gravity (KG). The transverse center of gravity (TCG) may also be determined for mobile offshore drilling units (MODUs) and other vessels which are asymmetrical about the centerline or whose internal arrangement or outfitting is such that an inherent list may develop from off-center weight. Because of their nature, other special considerations not specifically addressed in this guide may be necessary for some MODUs.

1.2 This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Terminology

2.1 Definitions:

2.1.1 inclining experiment—involves moving a series of known weights, normally in the transverse direction, and then measuring the resulting change in the equilibrium heel angle of the vessel. By using this information and applying basic naval architecture principles, the vessel’s vertical center of gravity (KG) is determined.

2.1.2 light ship—a vessel in the light ship condition (Condition I) is a vessel complete in all respects, but without consumables, stores, cargo, crew and effects, and without any liquids on board except that machinery fluids, such as lubricants and hydraulics, are at operating levels.

2.1.3 lightweight survey—this task involves taking an audit of all items which must be added, deducted, or relocated on the vessel at the time of the stability test so that the observed condition of the vessel can be adjusted to the light ship condition. The weight, longitudinal, transverse, and vertical location of each item must be accurately determined and recorded. Using this information, the static waterline of the ship at the time of the stability test as determined from measuring the freeboard or verified draft marks of the vessel, the vessel’s hydrostatic data, and the seawater density; the light

ship displacement and longitudinal center of gravity can be obtained. The transverse center of gravity may also be calculated, if necessary.

3. Significance and Use

3.1 From the light ship characteristics one is able to calculate the stability characteristics of the vessel for all conditions of loading and thereby determine whether the vessel satisfies the applicable stability criteria. Accurate results from a stability test may in some cases determine the future survival of the vessel and its crew, so the accuracy with which the test is conducted cannot be overemphasized. The condition of the vessel and the environment during the test is rarely ideal and consequently, the stability test is infrequently conducted exactly as planned. If the vessel is not 100% complete and the weather is not perfect, there ends up being water or shipyard trash in a tank that was supposed to be clean and dry and so forth, then the person in charge must make immediate decisions as to the acceptability of variances from the plan. A complete understanding of the principles behind the stability test and a knowledge of the factors that affect the results is necessary.

4. Theory

4.1 The Metacenter—(See Fig. 1). The transverse metacenter (M) is based on the hull form of a vessel and is the point around which the vessel’s center of buoyancy (B) swings for small angles of inclination (0 to 4° unless there are abrupt changes in the shape of the hull). The location of B is fixed for any draft, trim, and heel, but it shifts appreciably as heel increases. The location of B shifts off the centerline for small angles of inclination, but its height above the molded keel (K) will stay essentially the same. The height of M trim. The height of about 4°, as the ship is inclined at constant displacement and hand, is essentially fixed over a range of heeling angles up to angles of inclination, but its height above the keel (K) increases. The location of any draft, trim, and heel, but it shifts appreciably as heel changes in the shape of the hull). The location of small angles of inclination (0 to 4° unless there are abrupt

4.2 Metacentric Height—The vertical distance between the center of gravity (G) and M is called the metacentric height (GM). At small angles of heel, GM is equal to the initial slope of the righting arm (GZ) curve and is calculated using the relationship, GZ = GM sin θ. GM is a measure of vessel stability that can be calculated during an inclining experiment. As shown in Fig. 2, moving a weight (W) across the deck a distance (x) will cause a shift in the overall center of gravity (G–G’) of the vessel equal to (W)(x)/displ and parallel to the movement of W. The vessel will heel over to a new equilibrium heel angle where the center of buoyancy (B’) will once again be directly under the center of gravity (G’). Because the angle of inclination during the inclining experiment is small, the shift in G can be approximated by GM tan θ and then equated to (W)(x)/displ. Rearranging this equation slightly results in the following equation:

\[ GM = \frac{(W)(x)}{(\text{displ})(\tan \theta)} \]  

(1)

Since GM and displ remain constant throughout the inclining experiment the ratio (W)(x)/tan θ will be a constant. By carefully planning a series of weight movements, a plot of tangents is made at the appropriate moments. The ratio is measured as the slope of the best represented straight line drawn through the plotted points as shown in Fig. 3, where three angle indicating devices have been used. This line does not necessarily pass through the origin or any other particular point, for no single point is more significant than any other point. A linear regression analysis is often used to fit the straight line.

4.3 Calculating the Height of the Center of Gravity Above the Keel—KM is known for the draft and trim of the vessel during the stability test. The metacentric height (GM), as calculated above, is determined from the inclining experiment. The difference between the height KM and the distance GM is the height of the center of gravity above the keel (KG). See Fig. 4.

4.4 Measuring the Angle of Inclination—(See Fig. 5.) Each time an inclining weight (W) is shifted a distance (x), the vessel will settle to some equilibrium heel angle, θ. To measure this angle (θ) accurately, pendulums or other precise instruments are used on the vessel. When pendulums are used, the two sides
of the triangle defined by the pendulum are measured. \( Y \) is the length of the pendulum wire from the pivot point to the batten and \( Z \) is the distance the wire deflects from the reference position at the point along the pendulum length where transverse deflections are measured. Tangent \( \theta \) is then calculated:

\[
\tan \theta = \frac{Z}{Y}
\]  

(2)

Plotting all of the readings for each of the pendulums during the inclining experiment aids in the discovery of bad readings. Since \((W(x))/\tan \theta\) should be constant, the plotted line should be straight. Deviations from a straight line are an indication that there were other moments acting on the vessel during the inclining. These other moments must be identified, the cause corrected, and the weight movements repeated until a straight line is achieved. Figs. 6-9 illustrate examples of how to detect some of these other moments during the inclining and a recommended solution for each case. For simplicity, only the average of the readings is shown on the inclining plots.

4.5 Free Surface—During the stability test, the inclining of the vessel should result solely from the moving of the inclining weights. It should not be inhibited or exaggerated by unknown moments or the shifting of liquids on board. However, some liquids will be aboard the vessel in slack tanks so a discussion of “free surface” is appropriate.

4.5.1 Standing Water on Deck—Decks should be free of water. Water trapped on deck may shift and pocket in a fashion similar to liquids in a tank.

4.5.2 Tankage During the Inclining—If there are liquids on board the vessel when it is inclined, whether in the bilges or in the tanks, it will shift to the low side when the vessel heels. This shift of liquids will exaggerate the heel of the vessel. Unless the exact weight and distance of liquid shifted can be precisely calculated, the \( GM \) from formula (1) will be in error. Free surface should be minimized by emptying the tanks completely and making sure all bilges are dry or by completely

**FIG. 3 A Typical Incline Plot**

**FIG. 4 Relationship between GM, KM, and KG**

**FIG. 5 Measuring the Angle of Inclination**

**FIG. 6 Excessive Free Liquids**

*NOTE—Recheck all tanks and voids and pump out as necessary; redo all weight movements and recheck freeboard and draft readings.*

**FIG. 7 Port and Starboard Tangents**

**FIG. 8 Relationship between Port and Starboard Moments**

**FIG. 9 Measuring the Angle of Inclination**
filling the tanks so that no shift of liquid is possible. The latter method is not the optimum because air pockets are difficult to remove from between structural members of a tank, and the weight and center of the liquid in a full tank must be accurately determined to adjust the light ship values accordingly. When tanks must be left slack, it is desirable that the sides of the tanks be parallel vertical planes and the tanks be regular in shape (that is, rectangular, trapezoidal, and so forth) when viewed from above, so that the free surface moment of the liquid can be accurately determined. The free surface moment of the liquid in a tank with parallel vertical sides can be readily calculated by the formula:

\[
\text{Free surface (ft}^2\text{tons)} = \frac{1}{12} b^3 Q
\]

where

- \( l \) = length of tank, ft,
- \( b \) = breadth of tank, ft, and
- \( Q \) = specific volume of liquid in tank (ft\(^3\)/ton).

(See Annex A3 for fuel oil conversions or measure \( Q \) directly with a hydrometer.)

Free surface correction is independent of the height of the tank in the ship, location of the tank, and direction of heel.

4.5.3 As the width of the tank increases, the value of free surface moment increases by the third power. The distance available for the liquid to shift is the predominant factor. This is why even the smallest amount of liquid in the bottom of a wide tank or bilge is normally unacceptable and should be removed before the inclining experiment. Insignificant amounts of liquids in V-shaped tanks or voids (for example, a chain locker in the bow), where the potential shift is negligible, may remain if removal of the liquid would be difficult or would cause extensive delays.

5. Preparations for the Stability Test

5.1 General Condition of the Vessel—A vessel should be as complete as possible at the time of the stability test. Schedule the test to minimize the disruption in the vessel’s delivery date or its operational commitments. The amount and type of work left to be completed (weights to be added) affects the accuracy of the light ship characteristics, so good judgment must be used. If the weight or center of gravity of an item to be added cannot be determined with confidence, it is best to conduct the
stability test after the item is added. Temporary material, tool boxes, staging, trash, sand, debris, and so forth on board should be reduced to absolute minimum during the stability test.

5.2 Tankage—Include the anticipated liquid loading for the test in the planning for the test. Preferably, all tanks should be empty and clean or completely full. Keep the number of slack tanks to a minimum. The viscosity of the fluid and the shape of the tank should be such that the free surface effect can be accurately determined.

5.2.1 Slack Tanks:
5.2.1.1 The number of slack tanks should normally be limited to one pair of port and starboard tanks or one centerline tank of the following:
(a) Freshwater reserve feed tanks,
(b) Fuel/diesel oil storage tanks,
(c) Fuel/diesel oil day tanks,
(d) Lube oil tanks,
(e) Sanitary tanks, or
(f) Potable water tanks.
5.2.1.2 To avoid pocketing, slack tanks should normally be of regular (that is, rectangular, trapezoidal, and so forth) cross section and be 20 to 80 % full if they are deep tanks and 40 to 60 % full if they are double-bottom tanks. These levels ensure that the rate of shifting of liquid remains constant throughout the heel angles of the stability test. If the trim changes as the vessel is inclined, then consideration must also be given to longitudinal pocketing. Slack tanks containing liquids of sufficient viscosity to prevent free movement of the liquids, as the vessel is inclined (such as Bunker C at low temperature), should be avoided since the free surface cannot be calculated accurately. A free surface correction for such tanks should not be used unless the tanks are heated to reduce viscosity. Communication between tanks should never be allowed. Cross connections, including those via manifolds, should be closed. Equal liquid levels in slack tank pairs can be a warning sign of open cross connections. A bilge, ballast, and fuel oil piping plan can be referred to, when checking for cross-connection closures.

5.2.2 Pressed Up Tanks—Pressed up means completely full with no voids caused by trim or inadequate venting. Anything less than 100 % full, for example, the 98 % condition regarded as full for operational purposes, is not acceptable. The vessel should be rolled from side to side to eliminate entrapped air before taking the final sounding. Special care should be taken when pressing fuel oil tanks to prevent accidental pollution. An example of a tank that would appear “pressed up,” but actually contained entrapped air is shown in Fig. 10.

5.2.3 Empty Tanks—It is generally not sufficient simply to pump tanks until suction is lost. Enter the tank after pumping to determine if final stripping with portable pumps or by hand is necessary. The exceptions are very narrow tanks or tanks where there is a sharp deadrise, since free surface would be negligible. Since all empty tanks must be inspected, all manholes must be open and the tanks well ventilated and certified as safe for entry. A safe testing device should be on hand to test for sufficient oxygen and minimum toxic levels.

5.3 Mooring Arrangements—The importance of good mooring arrangements cannot be overemphasized. The arrangement selection will be dependent upon many factors. Among the most important are depth of water, wind, and current effects. Whenever possible, the vessel should be moored in a quiet, sheltered area free of extraneous forces such as propeller wash from passing tugs or sudden discharges from shoreside pumps. The depth of water under the hull should be sufficient to ensure that the hull will be entirely free of the bottom. The tide conditions and the trim of the vessel during the test must be considered. Before the test, measure the depth of water and record in as many locations as necessary to ensure the vessel will not contact the bottom. If marginal, conduct the test during high tide or move the vessel to deeper water.

5.3.1 The vessel should be held by lines at the bow and the stern, attached to temporary pad eyes installed as close as possible to the centerline of the vessel and as near the waterline as practical. If temporary pad eyes are not feasible, then lines can be secured to bollards or cleats, or both, on the deck. This arrangement requires that the lines be slackened when the ship is heeled away from the dock. The preferred arrangement is with the vessel lying in a slip where it can be moored as shown in Fig. 11. In this case, the lines can be kept taut to hold the vessel in place, yet allowing unrestricted heeling. Note, however, that wind or current, or both, may cause a superimposed heeling moment to act on the vessel throughout the test. For steady conditions, this will not affect the results. Gusty wind or uniformly varying wind or current, or both, will cause these
superimposed heeling moments to change, which may require additional test points to obtain a valid test. The need for additional test points can be determined by plotting test points as they are obtained.

5.3.2 Where the vessel can be moored to one side only, it is good practice to supplement the bow and stern lines with two spring lines to maintain positive control of the vessel, as shown in Fig. 12. The leads of the spring lines should be as long as practicable. Provide cylindrical camels between the vessel and the dock. All lines should be slack, with the vessel free of the pier and camels, when taking readings.

5.3.2.1 If the vessel is held off the pier by the combined effect of the wind and current, and the bow and stern lines are secured at centerline near the waterline, they can be taut. This is essentially the same as the preferred arrangement described in 5.3.1. As in 5.3.1, varying wind or current, or both, will cause some distortion of the plot.

5.3.2.2 If the vessel is pressed against the camels by wind or current, or both, all lines should be slack. The cylindrical camels will prevent binding, but again there will be an unavoidable superimposed heeling moment as a result of the ship bearing against the camels. This condition should be avoided but when used, give consideration to pulling the ship free of the dock and camels, and letting the ship drift as readings are taken.

5.3.2.3 Another acceptable arrangement is where the combined wind and current are such that the ship may be controlled by only one line at either the bow or the stern. In this case the control line need not be attached near the waterline, but it should be led from on or near the center line of the ship. With all lines but one slack, the ship is free to veer with the wind or current, or both, as readings are taken. This can sometimes be troublesome because varying wind or current, or both, can cause distortion of the plot.

5.3.3 If a floating crane is used for handling inclining weights it should not be moored to the ship.

5.3.4 Remove the access ramps. Power lines, hoses, and so forth connected to shore should be at a minimum and kept slack at all times.

5.4 List and Trim—To simplify calculations the vessel should be as close as possible to even list and design trim and have sufficient draft so that any abrupt changes in the waterplane will be avoided as the ship is inclined from side to side. If the vessel has a bow appendage, such as a bulbous bow or sonar dome, hard chine, or transom stern at the waterline, then give consideration to changing the draft or trim to ensure there is a minimum change in the waterplane area as the vessel is heeled from side to side. Trim different from design of up to 1% of LBP (length between perpendiculars) is normally acceptable when using hydrostatic data calculated at design trim. Exercise caution when applying the “1 % rule of thumb” to ensure that excessive error, as would result from a significant change in the waterplane area during heeling, is not introduced into the stability calculations. With inclining weights in the initial position, up to 1/2° of list is acceptable. If the list exceeds this, use leveling weights to put the vessel in an acceptable condition.

5.5 Test Weights—The total weight used should be sufficient to provide a minimum inclination of 1° and a maximum of 4° of heel.

5.5.1 One approach that can be taken to estimate how much weight is needed follows:

5.5.1.1 Measure the maximum athwartships distance (x) that is available on deck to shift the weights as shown in Fig. 13. 5.5.1.2 Estimate the draft the vessel will be at for the stability test and find the corresponding displacement from the vessel’s hydrostatic data.

5.5.1.3 Estimate the GM of the vessel by estimating its center of gravity (KG) and subtracting that value from KM, obtained from the hydrostatic data for the appropriate draft;

\[ GM = KM - KG \]  

5.5.1.4 Estimate the total weight (W) required by the following formula:

\[ W = \frac{GM \cdot (\tan \theta \cdot \text{displ})}{x} \]

where \( \theta \) is the desired angle of inclination between 1 and 4°. 5.5.1.5 It would be prudent to have additional weights readily available to compensate for any inaccurate estimates.

5.5.2 Test weights should be compact and of such a configuration that the KG (vertical center of gravity) of the weights can be accurately determined. Weights, such as porous concrete, that can absorb significant amounts of moisture, should only be used if they were weighed just before the stability test or if recent weight certificates are presented. Mark each weight with an identification number and weight. For small vessels, drums completely filled with water may be used. Drums should normally be full and capped to allow accurate weight control.

5.5.2.1 Certify test weights using a certificated scale. Perform the weighing close enough in time to the stability test to ensure that the measured weight is accurate. The time since weighing depends on the construction of the weight.

---

![FIG. 12 An Acceptable Alternate Mooring Arrangement](image1)

![FIG. 13 Movement of the Test Weights](image2)
5.5.3 A crane of sufficient capacity and reach, or some other means, must be available during the stability test to shift weights on the deck in an expeditious and safe manner.

5.5.4 Take precautions to ensure that the decks are not overloaded during weight movements. If deck strength is questionable, then perform a structural analysis to determine if existing framing can support the weight.

5.5.5 The test weights should be on board and in place before the scheduled time of the stability test.

5.6 **Pendulums:**

5.6.1 Use a minimum of three pendulums to allow identification of bad readings at any one pendulum station. They should each be located in an area protected from the wind. If this is not possible, then erect a screen around the exposed portions of the pendulums. Good locations for pendulums are ladder trunks, elevator shafts, hatchways, or any access way passing through decks.

5.6.2 The pendulums should be long enough to give a measured deflection, to each side of upright, of at least 6 in. Generally, this will require a pendulum length of at least 10 ft. Usually, the longer the pendulum the greater the accuracy of the test; however, if excessively long pendulums are used on a tender ship, the pendulums may not settle down and the accuracy of the pendulums would then be questionable. On smaller vessels, where there is insufficient headroom to hang long pendulums, obtain the 6-in. deflection by increasing the test weight so as to increase the list. The typical inclination is between 2 and 3° but in no case should the maximum angle of list be greater than 4°. As shown in Fig. 14, the pendulums must be at least 87 in. long to get at least 6 in. of deflection without exceeding the 4° maximum heel.

5.6.3 If the pendulums are of different lengths, the possibility of collusion between station recorders is avoided. The pendulum wire should be piano wire or other monofilament material. The top connection of the pendulum should afford unrestricted rotation of the pivot point. An example is that of a washer with the pendulum wire attached suspended from a nail.

5.6.4 Provide a trough filled with a thick oil to dampen oscillations of the pendulum after each weight movement. It should be deep enough to prevent the pendulum weight from touching the bottom.

5.6.5 The use of a winged plumb bob at the end of the pendulum wire can also help to dampen the pendulum oscillations in the oil.

5.6.6 The battens should be smooth, light-colored wood, ½ to ¾ in. thick, and should be securely fixed in position so that an inadvertent contact will not cause them to shift. The batten should be aligned close to the pendulum wire but not in contact with it.

5.6.7 The pendulums should be in place before the scheduled time of the stability test.

5.6.8 A typical satisfactory arrangement is shown in Fig. 15. The pendulums may be placed in any location on the vessel, longitudinally and transversely.

5.6.9 If the person conducting the test desires to substitute inclinometers or other measuring devices for the pendulums, complete prior testing of the measuring devices to verify their accuracy before actual substitution for the pendulums. It is recommended that the inclinometers or other measuring devices be used in conjunction with the pendulums instead of using only other devices and no pendulums.

5.7 **Communications Arrangements:**

5.7.1 One person at a central control station should have complete control over all personnel involved in the test.
5.7.2 There should be efficient two-way communications between central control and the weight handlers and between central control and each pendulum station.
5.7.3 Shelter the central control station from the elements, and have adequate lighting so that a plot of tangents versus heeling moments can be made during the test. It is desirable that the weight handlers be directly observed from the control station.
5.8 Additional Requirements:
5.8.1 Annex A1 contains additional requirements that must be met, if U.S. Coast Guard approval of the stability test is needed.
5.8.2 Annex A2 contains additional requirements that must be met for stability tests on U.S. Navy vessels.

6. Plans and Equipment Required
6.1 Plans—The person in charge of the inclining should have available a copy of the following at the time of the stability test:
   6.1.1 Lines plan,
   6.1.2 Curves of form (hydrostatic curves) or hydrostatic data,
   6.1.3 General arrangement plan of decks, holds, inner bottoms, and so forth,
   6.1.4 Outboard profile,
   6.1.5 Inboard profile,
   6.1.6 Midship section,
   6.1.7 Capacity plan showing capacities and vertical and longitudinal centers of gravity of cargo spaces, tanks, and so forth,
   6.1.8 Tank sounding tables,
   6.1.9 Draft mark locations, and
   6.1.10 Docking drawing with keel profile and draft mark corrections (if available).
6.2 Equipment—Besides the physical equipment necessary such as the inclining weights, pendulums, small boat, and so forth, the following are necessary and should be provided by or made available to the person in charge of the inclining:
   6.2.1 Three engineering scales for measuring pendulum deflections (rules should be subdivided into at least tenths of an inch),
   6.2.2 Three sharp pencils for marking pendulum deflections,
   6.2.3 Chalk for marking the various positions of the inclining weights,
   6.2.4 A sufficiently long measuring tape for measuring the movement of the weights and locating different items on board,
   6.2.5 A sufficiently long sounding tape for sounding tanks and taking freeboard readings,
   6.2.6 One or more specific gravity hydrometers, either 60°F/15°C (ASTM 125) or other, with range sufficient to cover 0.999 to 1.030, to measure the specific gravity of the water in which the vessel is floating (a quality hydrometer for measuring specific gravity of less than 1.000 may be needed in some locations),
   6.2.7 Other hydrometers as necessary to measure the specific gravity of any liquids on board,
   6.2.8 Graph paper to plot inclining moments versus tangents,
   6.2.9 A straight edge to draw the measured waterline on the lines drawing,
   6.2.10 A pad of paper to record data,
   6.2.11 An explosion proof testing device to check for sufficient oxygen and absence of lethal gases in tanks and other closed spaces such as voids and cofferdams,
   6.2.12 A thermometer, and
   6.2.13 Draft tubes (if necessary).

7. Procedure
7.1 The inclining experiment, the freeboard/draft readings, and the survey, may be conducted in any order and still achieve the same results. If the person conducting the stability test is confident that the survey will show that the vessel is in an acceptable condition and there is the possibility of the weather becoming unfavorable, then it is suggested that the inclining be performed first and the survey last. If the person conducting the test is doubtful that the vessel is complete enough for the test, it is recommended that the survey be performed first since this could invalidate the entire test, regardless of the weather conditions. It is very important that all weights, the number of people on board, and so forth, remain constant throughout the test. Appendix X1 contains a stability test check list that can be used to make a quick check that the procedure is correctly followed.

7.1.1 Initial Walk Through and Survey—The person responsible for conducting the stability test should arrive on board the vessel well in advance of the scheduled time of the test to ensure that the vessel is properly prepared for the test. If the ship to be inclined is large, a preliminary walk-through may need to be done the day preceding the actual incline. To ensure the safety of personnel conducting the walk-through, and to improve the documentation of surveyed weights and deficiencies, at least two persons should make the initial walk-through. Things to check include: all compartments are open, clean, and dry, tanks are well ventilated and gas free; movable or suspended items are secured and their position documented; pendulums are in place; weights are on board and in place; a crane or other method for moving weights is available; and the necessary plans and equipment are available. Before beginning the stability test, the person conducting the test should:

7.1.1.1 Consider the weather conditions. The combined adverse effect of wind, current, and sea may result in difficulties or even an invalid test due to the following:
   (a) Inability to record freeboards and drafts accurately,
   (b) Excessive or irregular oscillations of the pendulums, and
   (c) Variations in unavoidable superimposed heeling moments.
In some instances, unless conditions can be sufficiently improved by moving the vessel to a better location, it may be necessary to delay or postpone the test. Any significant quantities of rain, snow, or ice must be removed from the vessel before the test.

7.1.1.2 Make a quick overall survey of the vessel to make sure the vessel is complete enough to conduct the test and to ensure that all equipment is in place.

7.1.1.3 Enter all empty tanks after it is determined that they are well ventilated and gas free to ensure that they are dry and
free of debris. Ensure that any pressed up tanks are indeed full and free of air pockets.

7.1.1.4 Survey the entire vessel to identify all items that need to be added to the vessel, removed from the vessel, or relocated on the vessel to bring the vessel to the light ship condition. Each item must be clearly identified by weight and vertical and longitudinal location. If necessary, record also the transverse location. The inclining weights, the pendulums, any temporary equipment and dunnage, and the people on board during the stability test are all among the weights to be removed to obtain the light ship condition. The person calculating the light ship characteristics from the data gathered during the incline and survey or the person reviewing the stability test, or both, may not have been present during the test and must be able to determine the exact location of the items from the data recorded and the vessel’s drawings. Any tanks containing liquids must be accurately sounded and the soundings recorded. Table 1 is an example of just a few typical entries from a survey.

(a) It is recognized that the weight of some items on board, or that are to be added, may have to be estimated. If this is necessary, it is in the best interest of safety to be on the safe side when estimating, so the following rules of thumb should be followed:

(1) When estimating weights to be added:
   – estimate high for items to be added high in the vessel, and
   – estimate low for items to be added low in the vessel.

(2) When estimating weights to be removed:
   – estimate low for items to be removed from high in the vessel, and
   – estimate high for items to be removed from low in the vessel.

7.1.2 Freeboard/Draft Readings:

7.1.2.1 Take freeboard/draft readings to establish the position of the waterline to determine the displacement of the vessel at the time of the stability test. It is recommended that at least five freeboard readings, approximately equally spaced, be taken on each side of the vessel or that all draft marks (forward, midship, and aft) be read on each side of the vessel. Take draft mark readings to assist in determining the waterline defined by freeboard readings or to verify the vertical location of draft marks on vessels where their location has not been confirmed. The locations for each freeboard reading should be clearly marked. The longitudinal location along the vessel must be accurately determined and recorded since the (molded) depth at each point will be obtained from the vessel’s lines. All freeboard measurements should include a reference note clarifying the inclusion of the coaming in the measurement and the coaming height.

7.1.2.2 Read draft and freeboard readings immediately before or immediately after the inclining test. Weights must be on board and in place and all personnel who will be on board during the test including those who will be stationed to read the pendulums should be on board and in location during these readings. This is particularly important on small vessels. If readings are made after the test, maintain the vessel in the same condition as during the test. For small vessels, it may be

\(^a^Can be determined later by the naval architect from drawings or sounding tables, or both.
necessary to counterbalance the list and trim effects of the freeboard measuring party. When possible, take readings from a small boat.

7.1.2.3 The mooring lines should be slack such that the vessel floats freely. A check should be made that the vessel is not resting on the bottom.

7.1.2.4 Determine the specific gravity of the flotation water at this time. Take samples from a sufficient depth of the water to ensure a true representation of the flotation water and not merely surface water, which could contain fresh water from run off of rain. Place a hydrometer in a water sample and read and record the specific gravity. For large vessels, it is recommended that samples of the flotation water be taken forward, midship, and aft and the readings averaged. For small vessels, one sample taken from midships should be sufficient. A conversion table from specific gravity to specific volume is contained in Annex A3. Take the temperature of the water and correct the measured specific gravity for deviation from the standard, if necessary. A correction to water specific gravity is not necessary if the specific gravity is determined at the inclining experiment site. Correction is necessary if specific gravity is measured when sample temperature differs from the temperature at the time of the inclining (for example, if check of specific gravity is done at the office).

7.1.2.5 A small boat should be available to aid in the taking of freeboard and draft mark readings. It should have low freeboard to permit accurate observation of the readings.

7.1.2.6 A draft mark reading may be substituted for a given freeboard reading at that longitudinal location if the height and location of the mark has been verified to be accurate by a keel survey while the vessel was in drydock.

7.1.2.7 A device, such as a draft tube, can be used to improve the accuracy of freeboard/draft readings by damping out wave action.

7.1.2.8 The dimensions given on a vessel’s lines drawing are normally molded dimensions. In the case of depth (D), this means the distance from the inside of the bottom shell to the inside of the deck plate. To plot the vessel’s waterline on the lines drawing, convert the freeboard readings to molded drafts (d). See Fig. 16. If the freeboard is measured from the main deck to the waterline:

\[ d = D + t - f \] (6)

See Fig. 17. If the freeboard is measured from the top of the bulwark to the waterline:

\[ d = D + t + b - f \] (7)

Similarly, correct the draft mark readings from extreme (bottom of keel) to molded (top of keel) before plotting. Resolve any discrepancy between the freeboard/draft readings.

7.1.2.9 Calculate the mean draft (average of port and starboard reading) for each of the locations where freeboard/draft readings are taken and plotted on the vessel’s lines drawing or outboard profile to ensure that all readings are consistent and together define the correct waterline. The resulting plot should yield either a straight line or a waterline which is either hogged or sagged. If inconsistent readings are obtained, retake the freeboards/drafts.

7.1.3 The Inclining Experiment:

7.1.3.1 Before any weight movements, check the following:
(a) Check the mooring arrangement to ensure that the vessel is floating freely. (Do this just before each reading of the pendulums.)

(b) Measure the pendulums and record their lengths. The pendulums should be aligned so that when the vessel heels, the wire will be close enough to the batten to ensure an accurate reading but will not come into contact with the batten. The typical satisfactory arrangement is shown in Fig. 15.

(c) Mark the initial position of the weights on the deck. This can be done by tracing the outline of the weights on the deck.

(d) The communications arrangement is adequate.
(e) All personnel are in place.

7.1.3.2 Run a plot during the test to ensure that acceptable data is being obtained. Typically, the abscissa of the plot will be heeling moment (weight times distance) and the ordinate will be the tangent of the heel angle (deflection of the pendulum divided by the length of the pendulum).

7.1.3.3 The standard test uses eight weight movements. Movement No. 8, a recheck of the zero point, may be omitted if a straight line plot is achieved after Movement No. 7.

7.1.3.4 The weight movements shown in Fig. 18 give a good spread of points on the test plot.

7.1.3.5 Once everything and everyone is in place, obtain the zero position and conduct the remainder of the experiment as quickly as possible, while maintaining accuracy and proper procedures, to minimize the possibility of a change in environmental conditions during the test.

7.1.3.6 Before each pendulum reading, each pendulum station should report to the control station when the pendulum has stopped swinging. Then, the control station will give a “standby” warning and then a “mark” command. When “mark” is given, the batten at each position must be marked at the location of the pendulum wire. If the wire was oscillating slightly, take the center of the oscillations as the mark. If any of the pendulum readers does not think the reading was a good one, the reader should advise the control station and the point should be retaken for all pendulum stations. Likewise, if the control station suspects the accuracy of a reading, it should be repeated for all the pendulum stations. Next to the mark on the batten should be written the number of the weight movement, such as zero for the initial position and one through seven for the weight movements.

7.1.3.7 Make each weight movement in the same direction, normally transversely, so as not to change the trim of the vessel. After each weight movement, measure the distance the weight was moved (center to center) and calculate the heeling moment by multiplying the distance by the amount of weight moved. Calculate the tangent for each pendulum by dividing the deflection by the length of the pendulum. Plot the three resultant tangents on the graph. Provided there is good agreement among the pendulums with regard to the tan θ value, the average of the three pendulum readings may be graphed instead of plotting each of the readings.

7.1.3.8 If a straight line plot is achieved after the initial zero and six weight movements, the stability test is complete and the second check at zero may be omitted. If a straight line plot is not achieved, those weight movements that did not yield acceptable plotted points must be repeated or explained.

8. Report

8.1 Appendix X2 contains sample data sheets to record data during stability tests. It is suggested that these sheets be used so that no data is forgotten and so that the data is clear, concise, and consistent in form and format.

8.2 Appendix X3 contains sample sheets to aid in calculating the results of the stability test.

8.3 Alternatively, all calculations performed during the inclining and in preparation of the report may be carried out by a suitable computer program. Output generated by such a program may be used for presentation of all or partial data and calculations included in the test report if it is clear, concise, well documented, and generally consistent in form and content with the forms in Appendixes X2 and X3.

8.4 Annex A3 contains conversion factors to be used in changing specific gravity of fuel oil and water to specific volume.

9. Precision and Bias

9.1 The accuracy of the stability test is directly related to the accuracy of the measuring conditions at the time of the test. Many factors can influence the reliability of the information gained. The weather, the vessel loading, the mooring arrangements, the state of completion of the vessel, and so forth, can all significantly affect the final results of the test. Conditions during the measurement period should be such that readings can be recorded and then repeated to give consistent data. Make the required measurements, attempting to reach the following precision:

- Freeboards nearest 1⁄8 in.
- Draft marks nearest 1⁄8 in.
- Pendulum lengths nearest 1⁄6 in. (0.05 in. on a 1⁄10-in. scale)
- Survey weights 1 % of the weight (5 % for small items)
- Tank soundings nearest 1⁄8 in.

The precision used to read measurements does not guarantee the resulting overall accuracy of the test. If all procedures in this guide are followed, the test results should have satisfactory accuracy.
A1. Prior Notification To The Coast Guard Marine Safety Center—Written notification of the test must be sent to the Coast Guard Marine Safety Center (MSC) at least two weeks before the test. The MSC will make arrangements for an acceptable representative to witness the test.

A1.1 Details of Notification
Written notification should provide the following information:
A1.1.1 Identification of the vessel by name and shipyard hull number, if applicable.
A1.1.2 Date, time, and location of the test.
A1.1.3 Inclining weight data.
   (a) Type,
   (b) Amount (number of units and weight of each),
   (c) Certification,
   (d) Method of handling (that is, sliding rail or crane), and
   (e) Anticipated maximum angle of heel to each side.
A1.1.4 Pendulums
   Approximate location and length. (If a shipyard/naval architect desires to substitute inclinometers or other measuring devices for one or two of the three required pendulums, prior approval must be obtained from the MSC. The MSC might require that the devices be used in addition to the pendulums on one or more inclinings to verify their accuracy before allowing actual substitution for a pendulum.)
A1.1.5 Approximate trim.
A1.1.6 Condition of tanks.
A1.1.7 Estimated weights to deduct, to complete, and to relocate to place the vessel in its true light ship condition.
A1.1.8 Detailed description of any computer software to be used to aid in calculations during the inclining.
A1.1.9 Name and phone number of the person responsible for conducting the test.

A1.2 Alternate mooring arrangements will be considered if submitted for review before the test. Such arrangements should ensure that the vessel will be free to list without restraint for a sufficient period of time to allow the pendulums to damp out motion so that the readings can be recorded.

A1.3 Each of the test weights must be certified by a weigh master’s document and a copy provided to the Coast Guard representative. For small vessels, capped drums, completely filled with water, may be used. In such cases, the weight should be verified in the presence of the Coast Guard representative using a recently calibrated scale.

A1.4 If bad weather conditions are detected early enough and the weather forecast does not call for improving conditions, the Coast Guard representative should be advised before departure from the office and an alternate date scheduled.

A1.5 An estimate of work items that will be outstanding at the time of the stability test should be included as part of any test procedure submitted to the MSC. This is required so that the Coast Guard representative can advise the shipyard/naval architect if in their opinion the vessel will not be sufficiently complete to conduct the stability test and that it should be rescheduled. If the condition of the vessel is not accurately depicted in the test procedure and at the time of the stability test the Coast Guard witness considers that the vessel is in such condition that an accurate stability test cannot be conducted, the witness may refuse to accept the test and require that a test be conducted at a later date.

A1.6 A certified marine chemist’s certificate certifying that all fuel oil and chemical tanks are safe for human entry should be available, if necessary.

A1.7 If a computer program is used to perform calculations during the inclining, Coast Guard approval to use the program must be obtained prior to the test.

A1.8 Before departing the vessel, the person conducting the test and the Coast Guard representative should initial each sheet as an indication of their concurrence with the recorded data.

A1.9 A copy of the data should be forwarded to the MSC along with the stability test report.

A1.10 When completed, three copies of the stability test report should be submitted to the MSC for approval.

A1.11 The Coast Guard may alter or limit acceptance of any provision in this guide.

A1.12 When the American Bureau of Shipping is representing the Coast Guard during a stability test, the words, American Bureau of Shipping, should be substituted for the words, Coast Guard, and for the words, Marine Safety Center, in this annex.
A2. FOR STABILITY TESTS ON UNITED STATES NAVY (USN) VESSELS THE FOLLOWING ADDITIONAL REQUIREMENTS APPLY

A2.1 The inclining experiment shall be performed in accordance with the requirements set forth in Naval Ship’s Technical Manual, and as modified below. The stability test report shall be prepared on the forms described in the above technical manual.

A2.2 Photographs of topside arrangements including weather decks is required to document topside installations. Photographs of each draft mark reading are also required.

A2.3 A comprehensive survey of all compartments, tanks, and voids is required to determine the weight and center of gravity (vertical, longitudinal, and transverse) of all consumable loads, including personnel, ammunition, provisions, general stores, and liquids.

A2.4 Draft readings are required. Amidships marks should be read to determine hog or sag of ship. Projection draft marks and freeboard readings can be used to verify accuracy of draft mark readings.

A2.5 Inclining weights are moved transversely to produce at least two inclinations to port and two to starboard.

A2.6 Significant items of weight that are considered part of the lightship displacement but are subject to change or are readily removable are listed, as part of the report, by weight and center of gravity. These items include boats, armament, ballast, salvage gear, and yellow gear.

A2.7 It is desirable under most circumstances to incline the vessel at design trim. If however, the area of the waterplane will change substantially as the ship is heeled from side to side, then the trim should be altered, to minimize the change in the waterplane area during the incline. This may require that functions of wedges be calculated to correct for the trimmed conditions. The hydrostatics must be verified or recalculated, or both, if the as-trimmed waterplane area differs from the waterplane area at the design trim.

A2.8 The freeboard/draft mark readings must be taken simultaneously on both sides of the vessel, to ensure that any heel is properly recorded at the time of the stability test.

A2.9 The transverse center of gravity (TCG) must be determined for all ships.

A2.10 In presentation of incline results, incline plots are to be arranged such that the slope of the incline plot can be directly substituted into the \( GM \) formula as shown below.

\[
GM = \frac{\text{slope}}{\text{displ}}
\]

where slope of the line from the incline plot equals the (rise/run). Heeling moments must be on the ordinate and tangents must be on the abscissa. Fig. A2.1 gives an example of an acceptable plot.

\[2 \text{ NAVSEA 59086-C6-STM-000, Chapter 096, “Weights and Stability,” available from Commanding Officer, Naval Ships Weapon System Engineering Station, Code 5700, Port Hueneme, CA 93043.}\]
A3. CONVERSION TABLES FOR LIQUIDS

A3.1 Table A3.1 and Table A3.2 are based on the weight of 1 gal of water in air against brass weights at 60°F and 30-in. mercury at 45° latitude at sea level and 50% humidity. They were taken from the National Bureau of Standards Circular C-410.3

3 Available from National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899.

</table>
X1.1 Pre-Inclining:

1.________Vessel is complete or nearly so.
   (a) No major structural sections or major items of equip-
   ment to be added or removed.
   (b) No tanks with liquids not shown in the inclining
   procedure.
   (c) No extraneous gear and personnel on board the vessel.
2.________ Weather conditions are satisfactory.
   (a) No gusting winds. Steady light wind not causing
   motions is acceptable. Beam winds to be avoided. Wind speed
   normally acceptable if draft marks can be read.
   (b) No strong currents.
   (c) Not raining.
   (d) No waves. Ripples acceptable if can read freeboards to
   ½ in.
3.________ Depth of water is greater than draft of vessel.
4.________ All empty tanks should be opened and checked for
   liquids. All tanks containing liquids should be sounded for
   liquid levels. All tank levels should be recorded.
5.——— Weight certificates obtained or the weights used
   for the inclining actually weighed using certified scales.
6.——— Initial angle of heel is less than 0.5° and the trim
   difference from design is less than 1 % of the LBP. If more trim
   is allowed, as-trimmed hydrostatics must be used in calcula-
   tions.

Note: X1.1—In some cases, if trim is different from design, as-trimmed
hydrostatics must always be used (that is, Navy inclines).

X1.2 Freeboard/Draft Readings:

1.—— At least five freeboard readings on each side at
   approximately the same intervals along the length at readily
   identifiable locations (for example, ends of deck houses). A
   verified draft mark reading may be substituted for a freeboard
   reading.
   (a) Each data point is to consist of:
      1. Freeboard reading (f) taken from the top of the
         bulwark to the point where the plumb bob touches the water.
      2. Bulwark height (b) reading at each location.
      3. Deck plating thickness (t) from the structural plan.
      4. Molded depth (D) at each location from the lines
         plan.
   (b) Molded draft = molded depth plus bulwark height plus
      deck plating thickness minus freeboard reading
      \[ d = D + b + t - f \].
2.——— Draft mark readings:
   (a) Taken from a small boat.
   (b) Port and starboard; forward, midship, and aft.
   (c) Longitudinal locations from a known reference point.
3.——— Plot of waterline (draft versus distance from
   forward perpendicular).
   (a) Note that draft readings are extreme (bottom of keel)
   while drafts from freeboard readings are molded (top of keel).
4.——— Specific gravity of water (hydrometer reading) and
   water temperature readings.

X1.3 Weight Movements:

1.——— Pendulums:
   (a) At least three; can be located on different decks and do
   not have to be on centerline.
   (b) Length of pendulums is measured from the pivot point
   to the top of the batten.
   (c) Pendulums should be of different lengths; to get re-
   quired angle of deflection, pendulums need to be at least 10 ft
   long. The longer the better if sheltered from the wind.
   Pendulum unrestricted through maximum angle expected.
   (d) Thick oil in bucket to dampen movement of pendulums.
      Pendulums with dampers are recommended.
      (e) Pendulum support is fixed so it cannot be accidently
      moved during the inclining.
   2.——— Battens:
      (a) Pencil marks placed on battens to record the position
      of the pendulum wires.
      (b) Batten is fixed so it can not be accidently moved
      during the inclining.
      (c) Battens should never be reset once inclining begins and
      movements are being recorded.
3.——— Weights:
   (a) Record initial position (vertical, transverse, longitudinal
   distances from known reference points such as distance above
   the deck, distance from the end of a deckhouse and distance
   from the centerline).
4.——— Weight Movements:
   (a) At least three to each side of the reference position.
   (b) Deflection of the pendulums at maximum moment
   should be at least 6 in. to each side of the initial position.
   (c) Maximum angle of heel should not be greater than 4°;
   value of tangent must be less than 0.069 93. Typical angle of
   heel should be between 2 and 3°.
   (d) Moment equals weight times distance moved; calcu-
   lated and summed for all weights moved for each movement.
   (e) Tangent equals pendulum deflection divided by pendu-
   lum length. When calculating the tangent, the deflection and
   the length must be in the same units (that is, inches or feet).
   (f) During each movement, ensure that:
      1. There are no taut mooring lines other than those
         attached to temporary pads on centerline;
      2. Pendulum weight is not touching side of bucket; and
      3. Pendulum is not touching batten.
   (g) Plot of moment-tangent curve:
      1. Plot each tangent value calculated for each weight
         movement. The average of the three pendulum readings may
         be graphed instead of plotting each of the readings only if the
tan \( \theta \) values measured among the pendulums are consistent.

2. Plot must be a straight line but it doesn’t have to pass through the origin.

3. Curved line means unaccounted for free surface, gusting winds or the vessel is touching the bottom and should not be accepted.

X1.4 Post-Inclining:
1.________ Check drafts/freeboards to ensure consistency with first measurements.
   (a) Note that draft readings are extreme (bottom of keel) while drafts from freeboard readings are molded (top of keel).
2.________ Survey tanks if drafts have changed.

X1.5 Survey of Items to Be Added, Removed, or Relocated:
1.________ Record weight, vertical center of gravity, longitudinal center of gravity, and transverse center of gravity (if required) for each item. Weights become more critical as the size of the vessel becomes smaller.
2.________ Typical weights to add:
   (a) Liferafts/lifesaving equipment;
   (b) Seating;
   (c) Liquids in engines and other machinery;
   (d) Paneling;
   (e) CO\(_2\) bottles/firefighting equipment;
   (f) Fenders;
   (g) Deck coverings/tiles and underlaminets;
   (h) Cables for winches;
   (i) Lines and hawser;
   (j) Engineersroom insulation;
   (k) Ventilation ducts;
   (l) Galley equipment (stoves and refrigerators);
   (m) Mattresses;
   (n) Paint (on surfaces to be painted);
   (o) Dampers;
   (p) Electronic equipment in the pilothouse; and
   (q) Masts and navigation lights.
3.________ Typical weights to deduct:
   (a) Inclining weights and pendulum setup;
   (b) Personnel on board;
   (c) Liquids on board (in tanks and bilges but excluding liquids in engines and other machinery);
   (d) Workers equipment;
   (e) Scrap metal;
   (f) Scaffolding; and
   (g) Dunnage.
4.________ Typical weights to relocate:
   (a) Paneling;
   (b) Lifesaving equipment;
   (c) Fenders and mooring equipment; and
   (d) Fire-extinguishing equipment.

FIG. X2.4 Items To Be Relocated
Freeboard Readings

$f =$ measured freeboard,
$t =$ deck thickness,
$D =$ molded depth from lines drawing,
$b =$ measured bulwark height, and
$d =$ calculated molded draft.

Without Bulwark or Side Shell Coaming
\[ d = D + t - f \]

Or

With Bulwark or Side Shell Coaming
\[ d = D + t + b - f \]

Corrected displacement
Mean virtual metacentric height obtained from plot of inclining moment
moments versus tangents of angles of heel—
displacement × tangent
Correction for free surface
Mean metacentric height = G. M. =
Transverse metacenter above the base line corresponding to draft at L. C. F. (corrected for hog or sag)
Transverse metacenter above the base line corrected (for trim, and hog or sag)
C. G. above base line
Longitudinal metacenter above C. G.
Moment to alter trim 1 foot Long. GM × ∆
Trim by stern, bow
Trimming lever = Trim × moment to trim
L.C.B. forward, aft of amidships, which is ft forward, aft of frame No.
C. G. forward, aft of amidships
Period of complete roll
Apparent radius of gyration of vessel—k = \( \frac{T \sqrt{GM}}{1.108} \)
Rolling Constant—C = \( \frac{T \sqrt{GM}}{B} \)

\( ^{A} \) Water in bilges. The bilges should be entirely free of water; but should this be impossible, correction should be made in the derived GM. The details of this correction should form part of this report.

\( ^{B} \) If the trim is excessive, independent calculations should be made to obtain the positions of the center of buoyancy and transverse metacenter and the position of the center of gravity determined therefrom. These calculations should be incorporated in this booklet.

FIG. X3.10 Stability Test—Conclusive Remarks

**NOTE**—This sheet should be used for any explanations that may be required other than those covered by the notes on the previous sheets. In case the results of the stability test show that under certain conditions caution in loading and handling the vessel is necessary, particularly in regard to the effect of deck loads or free surface, a detailed statement to this effect should be made here.

FIG. X3.10 Stability Test—Conclusive Remarks
Standard Guide for Selection of Shipboard Incinerators

This standard is issued under the fixed designation F 1322; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope
   1.1 This guide covers selection criteria to assist procurers in selecting the appropriate incinerator for their needs.
   1.2 This guide is a companion document to Specification F 1323.
   1.3 This guide does not apply to incinerator systems on special incinerator ships, for example, for burning industrial wastes such as chemicals, manufacturing residues, and so forth.

2. Referenced Documents
   2.1 ASTM Standards:
       2.1.1 F 1323 Specification for Shipboard Incinerators
   2.2 Other Document:
       2.2.1 MARPOL 73/78

3. Selecting the Incinerator Size and Installed Location
   3.1 A number of factors will govern the selection of the size and type of shipboard incinerator and full consideration must be given to each. The installed operating location of the unit is of equal importance to ensure low-cost operating, ease of charging, ease of cleaning, and so forth. Consideration should be given to the following:
      3.1.1 Maximum amount of each type of waste that will be incinerated each day.
      3.1.2 The normal number of hours per day that the incinerator will be in operation: loading procedure batch/continuous over operating hours.
      3.1.3 Can wet and dry material be loaded into the incinerator so that a large volume of auxiliary fuel is not required?
      3.1.4 Can the incinerator be installed on the ship in a location near the major source of refuse so as to minimize the manpower requirements during loading operations?
      3.1.5 Will ashes be able to be removed easily if the incinerator is installed in the machinery space or on a lower deck? Will ash removal be manual (shoveling) or semiautomatic (plow)?

4. Estimating Daily Quantities of Waste to Be Incinerated
   4.1 Size of Ship’s Crew:
      4.1.1 Galley waste estimate: 2 lb per crew member per day.
      4.1.2 Crews quarters waste estimate: 1.5 lb per room per day.
   4.2 Number of Passengers Carried:
      4.2.1 Galley waste estimate: 3⁄4 lb per meal served.
      4.2.2 Passenger quarters waste estimate: 1.5 lb per room per day.
   4.3 Stores—Including amount of packages and packages that would add to the ship’s garbage.
   4.4 Spent oil.

5. Factors for Selection
   5.1 Type of Unit—Two-stage controlled air, or single-stage, compact high-temperature cyclone incinerator.
   5.2 Size of unit (number of people on board).
   5.3 Loading considerations (manual loader) (batch or continuous).
   5.4 Auxiliary liquid waste capability (sludge oil/waste oil).
   5.5 Installation considerations (indoor/outdoor).
   5.6 Environmental considerations (in port usage).
   5.7 Heat recover options (amount of steam or hot water).
   5.8 Ash removal.
   5.9 Induced draft fan requirements.
   5.10 Modular/package.
   5.11 Dimensions/weight.

6. Classification of Shipboard Wastes and Incinerators
   6.1 The basis for satisfactory incinerator operation is the proper analysis of the waste to be destroyed and the selection of proper equipment to best destroy that particular waste.
6.2 As a guide, mixtures of waste most commonly encountered have been classified into types of waste, together with the British Thermal Unit (Btu) values and moisture contents of the mixtures. A concentration of one specific waste in the mixture may change the Btu value or the moisture content, or both, of the mixture. A concentration of more than 10% by weight of catalogs, magazines, or packaged paper will change the density of the mixture and affect burning rates.

6.3 Similarly, incinerators have been classified by their capacities and by the types of wastes they are capable of incinerating.

6.4 Classification of Shipboard Wastes—The following classification of shipboard wastes differs from the definition of garbage as found in Annex V of MARPOL 73/78, which includes all of the types listed on this page.

6.4.1 Type 0—Trash, a mixture of highly combustible waste, such as paper, cardboard, cartons, wood boxes, and combustible floor sweepings from commercial and industrial activities. The mixtures contain up to 10% by weight of plastic bags, coated paper, laminated paper, treated corrugated cardboard, oil rags, and plastic or rubber scraps.

6.4.1.1 This type of waste contains 10% moisture, 5% incombustible solids, and has a heating value of 8500 Btu/lb as fired.

6.4.2 Type 1—Rubbish, a mixture of combustible waste, such as paper, cardboard cartons, wood scrap, foliage, and combustible floor sweepings, from domestic, commercial, and industrial activities. The mixture contains up to 20% moisture, 10% incombustible solids, and has a heating value of 6500 Btu/lb as fired.

6.4.2.1 This type of waste contains 25% moisture, 10% incombustible solids, and has a heating value of 4300 Btu/lb as fired.

6.4.3 Type 2—Refuse, consisting of an approximately even mixture of rubbish and garbage by weight.

6.4.3.1 This type waste is common to passenger ships occupancy, consisting of up to 50% moisture, 7% incombustible solids, and has a heating value of 4300 Btu/lb as fired.

6.4.4 Type 3—Garbage, consisting of animal and vegetable wastes from restaurants, cafeterias, galleys, sick bays, and like installations.

6.4.4.1 This type of waste contains up to 70% moisture, up to 5% incombustible solids, and has a heating value of 2500 Btu/lb as fired.

6.4.5 Type 4—Aquatic life forms and animal remains, consisting of carcasses, organs and solid organic wastes from vessels carrying animal type cargos, consisting of up to 85% moisture, 5% incombustible solids, and having a heating value range of 1000 Btu/lb as fired.

6.4.6 Type 5—By-product waste, liquid or semiliquid, such as tar, paints, solvents, sludge, oil, waste oil, and so forth, from shipboard operations. Btu values must be determined by the individual materials to be destroyed.

6.4.7 Type 6—Solid by-product waste, such as rubber, plastics, wood waste, and so forth, from industrial operations. Btu values must be determined by the individual materials to be destroyed.

---

4 The original source of data for these classifications is the Incinerator Institute of America Waste Classification, available from the Incinerator Institute of America, 60 E. 42nd St., New York, NY 10017.
Standard Specification for Shipboard Incinerators

This standard is issued under the fixed designation F 1323; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design, manufacture, performance, operation, functioning, and testing of incinerators intended to incinerate garbage and other shipboard wastes generated during the ship’s normal service (that is, maintenance, operational, domestic, and cargo-associated wastes).

1.2 This specification is a companion document to Guide F 1322.

1.3 This specification applies to those incinerator plants with capacities up to 1500 kW per unit.

1.4 Additional information is given in Appendix X1-Appendix X9.

1.5 This specification does not apply to systems on special incinerator ships, for example, for burning industrial wastes such as chemicals, manufacturing residues, and so forth.

1.6 This specification does not address the electrical supply to the unit nor the foundation connections and stack connections.

1.7 This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. If an incinerator is to be operated in littoral regions, the strictest governing regulations for those countries in which the incinerator may operate would form the requirement basis. See 5.11.

3. Terminology

3.1 Definitions:

3.1.1 cargo-associated waste—all materials that have become waste as a result of use on board a ship for cargo stowage and handling. Cargo-associated waste includes but is not limited to dunnage, shoring pallets, lining and packing materials, plywood, paper, cardboard, wire, and steel strapping.

3.1.2 cargo residues—for the purposes of this specification, the remnants of any cargo material on board that cannot be placed in proper cargo holds (loading excess and spillage) or which remain in cargo holds and elsewhere after unloading procedures are completed (unloading residual and spillage). However, cargo residues are expected to be in small quantities.

3.1.3 domestic waste—all types of food waste, sewage, and waste generated in the living spaces on board the ship.

3.1.4 fishing gear—any physical device or part thereof or combination of items that may be placed on or in the water.
with the intended purpose of capturing, or controlling for subsequent capture, living marine or freshwater organisms.

3.1.5 food wastes—any spoiled or unspoiled victual substances, such as fruits, vegetables, dairy products, poultry, meat products, food scraps, food particles, and all other materials contaminated by such waste, generated aboard ship, principally in the galley and dining areas.

3.1.6 garbage—all kinds of victual, domestic, and operational waste excluding fresh fish and parts thereof, generated during the normal operation of the ship and liable to be disposed of continuously or periodically. Those substances which are defined or listed in Annexes, other than Annex V, to the International Convention for the Preventing of Pollution From Ships, 1973, as modified by the Protocol of 1978 (MARPOL 73/78) are excluded.

3.1.7 graywater—drainage from galleys, pantries, showers, laundries, baths, and handbasins as long as it is not mixed with sewage.

3.1.8 incinerator—shipboard facilities for incinerating solid wastes approximating in composition to household waste and liquid wastes arising from the operation of the ship, for example, domestic waste, cargo-associated waste, maintenance waste, operational waste, cargo residues, fishing gear, and so forth. These facilities may be designed to use or not to use the heat energy produced.

3.1.9 maintenance waste—materials collected by the engine department and the deck department while maintaining and operating the ship, such as soot, machinery deposits, scraped paint, deck sweeping, wiping wastes, oily rags, and so forth.

3.1.10 oily rags—rags that have been saturated with oil as controlled in Annex I to the Convention. Contaminated rags are rags that have been saturated with a substance defined as a harmful substance in the other Annexes to the Convention.

3.1.11 operational wastes—all cargo-associated wastes and maintenance waste (including ash and clinkers) and cargo residues defined as garbage in 3.1.6.

3.1.12 plastic—a solid material that contains as an essential ingredient one or more synthetic organic high polymers and is formed (shaped) during either manufacture of the polymer or the fabrication into a finished product by heat or pressure, or both. Plastics have material properties ranging from hard and brittle to soft and elastic. Plastics are used for a variety of marine purposes including, but not limited to, packaging (vapor-proof barriers, bottles, containers, liners), ship construction (fiberglass and laminated structures, siding, piping, insulation, flooring, carpets, fabrics, paints and finishes, adhesives, electrical and electronic components), disposable eating utensils and cups, bags, sheeting, floats, fishing nets, strapping bands, rope, and line.

3.1.13 sewage—human body waste and the waste from toilets and other receptacles intended to receive or retain body wastes. Sewage is drainage and other waste from toilets, urinals, and water closet scuppers as well as drainage from medical premises and from spaces containing living animals.

3.1.14 ship—a vessel of any type operating in the marine environment and includes hydrofoil boats, air-cushion vehicles, submersibles, floating craft, and fixed or floating platforms.

3.1.15 sludge oil—residues from fuel and lubricating oil separators, waste lubricating oil from main and auxiliary machinery, waste oil from bilge water separators, drip trays, and so forth.

3.1.16 waste—useless, unneeded, or superfluous matter which is to be discarded.

4. Ordering Information

4.1 Orders shall include the following information, in accordance with Guide F 1322:

4.1.1 Sizing requirements.
4.1.2 Processing rate requirements.
4.1.3 Additional control requirements.
4.1.4 Any additional requirements required by the purchaser to meet special needs.

5. Materials and Manufacture

5.1 Metal parts of the incinerator exposed to the combustion process shall be made of materials listed in Section I of the ASME Boiler and Pressure Vessel Code.

5.2 Where welded construction is used, welded joint design details, welding, and nondestructive testing of the combustion chamber shall be in accordance with Section I of the ASME Code. Welders and weld procedures shall be qualified in accordance with Section IX of the ASME Code.

5.3 Piping and piping components associated with incinerators for fuel, sludge, and liquid cargo residues shall comply with ANSI B31.1 for design and material requirements. Fuel oil pressure piping between service pumps and burners shall have a relief valve fitted which will discharge into the suction line or back into the tank. Pressure piping shall be of seamless steel with a thickness of at least Schedule 80. Short lengths of steel, or annealed copper nickel, nickel copper, or copper pipe and tubing may be used at the burners. The use of nonmetallic materials for fuel lines is prohibited. Valves and fittings may be threaded in sizes up to and including 2-in. normal pipe size (NPS) (60-mm outside diameter), but threaded unions are not to be used on pressure lines in sizes 1-in. NPS (33-mm outside diameter) and over.

5.4 If equipped with an electrically, hydraulically, or pneumatically activated valve, the valve shall be designed to fail closed or in the safe position on loss of power whichever is more appropriate to the applicable system.

5.5 All rotating or moving mechanical and exposed electrical parts shall be protected against accidental contact. All electrical devices shall be enclosed in drip-proof or watertight enclosures.

5.6 The coatings or paints shall not contain any heavy metals, such as, chromium, lead, tin, and so forth, or other materials banned by federal, state, or local authorities.

5.7 Asbestos, mercury, cadmium, polychlorinated biphenyls (PCBs), and chlorinated plastics shall not be used in the construction of the incinerator or any subsystem, including gaskets or lagging materials.

5.8 Refractory shall be resistant to thermal shocks and resistant to normal ship’s vibration. The refractory design temperature shall be equal to the combustion chamber design temperature plus 20% (see 6.1).
5.9 Incinerating systems shall be designed such that corrosion will be minimized on the inside of the systems.

5.10 In systems equipped for incinerating liquid wastes, safe ignition and maintenance of combustion shall be ensured, for example, by a supplementary burner using gas oil/diesel oil or equivalent.

5.11 The incinerating furnace may be charged with solid waste either by hand or automatically. In every case, fire dangers must be avoided and charging must be possible without danger to the operating personnel.

5.11.1 For instance, where charging is carried out by hand, a charging lock may be provided which ensures that the charging space is isolated from the fire box as long as the filling hatch is open.

5.11.2 Where charging is not affected through a charging lock, an interlock shall be installed to prevent the charging door from opening while the incinerator is in operation or while the furnace temperature is above 220°C (428°F).

5.12 Incinerators equipped with a feeding sluice shall ensure that the material charged will move from the sluice to the combustion chamber. Examples for accomplishing this are the use of a clear path down or a mechanical pusher.

5.13 Interlocks shall be installed to prevent ash removal doors from opening while burning is in progress or while the furnace temperature is above 220°C (428°F).

5.14 The incinerator shall be provided with a safe observation port of the combustion chamber to provide visual control of the burning process and waste accumulation in the combustion chamber. Neither heat, flame, nor particles shall be able to pass through the observation port. An example of a safe observation port is high-temperature glass with a metal closure.

5.15 The outside surface of the combustion chamber(s) shall be shielded from contact such that people would not be exposed to extreme heat (maximum 20°C (68°F) above ambient temperature) or direct contact of surface temperatures exceeding 60°C (140°F). Examples for alternatives to accomplish this are a double jacket with airflow in between or an expanded metal jacket.

5.16 Safety interlocks shall be provided to ensure that the incinerator cannot be operated if the shock cooling subsystem is not functioning properly.

5.17 Electrical Requirements:

5.17.1 General—Installation requirements shall apply to controls, safety devices, and burners on incinerators.

5.17.1.1 A disconnecting means capable of being locked in the open position shall be installed at an accessible location at the incinerator so that the incinerator can be disconnected from all sources of electrical potential. This disconnecting means shall be an integral part of the incinerator or adjacent to it (see 7.1).

5.17.1.2 All rotating or moving parts that may cause injury shall be guarded to avoid accidental contact.

5.17.1.3 The electrical equipment shall be so arranged so that failure of this equipment will cause the fuel supply to be shut off.

5.17.1.4 The power supply to the electrical control system shall be from a two-wire branch circuit that has a grounded conductor; otherwise, an isolation transformer with a two-wire secondary shall be provided. When an isolation transformer is provided, one side of the secondary winding shall be grounded.

5.17.1.5 One side of all coils shall be electrically located in the grounded side of the circuit. All switches, contacts, and overcurrent devices shall be electrically located in the ungrounded or “hot” side of the circuit. All electrical contacts of every safety device installed in the same control circuit shall be electrically connected in series. However, special consideration shall be given to arrangements when certain devices are wired in parallel.

5.17.1.6 All electrical components and devices shall have a voltage rating commensurate with the supply voltage of the control system.

5.17.1.7 All electrical devices shall be at least NEMA Type 2 (Drip tight). Electric equipment exposed to the weather shall be at least NEMA Type 4.

5.17.1.8 All electrical and mechanical control devices shall be of a type tested and accepted by a nationally recognized testing agency.

5.17.1.9 The design of the control circuits shall be such that, limit, and primary safety controls shall directly open a circuit that functions to interrupt the supply of fuel to combustion units.

5.17.2 Overcurrent Protection:

5.17.2.1 Conductors for interconnecting wiring that is smaller than the supply conductors shall be provided with overcurrent protection based on the size of the smallest interconnecting conductors external to any control box.

5.17.2.2 Overcurrent protection for interconnecting wiring shall be located at the point where the smaller conductors connect to the larger conductors. However, overall overcurrent protection is acceptable if it is sized on the basis of the smallest conductors of the interconnecting wiring.

5.17.2.3 Overcurrent protection devices shall be accessible and their function shall be identified.

5.17.3 Motors:

5.17.3.1 Motors exposed to dripping or spraying oil or water shall be of drip-proof construction. All motors shall be fully guarded as installed.

5.17.3.2 Motors shall be provided with a corrosion-resistant nameplate specifying information in accordance with NEC, Article 430-7.

5.17.3.3 Motors shall be provided with running protection by means of integral thermal protection, or by overcurrent devices, or a combination thereof, in accordance with the manufacturer’s instructions that shall be based on the requirements of National Electrical Code, ANSI/NFPA No. 70.

5.17.3.4 Motors shall be rated for continuous duty and shall be designed for an ambient temperature of 50°C (122°F) or higher.

5.17.3.5 All motors shall be provided with terminal leads or terminal screws in terminal boxes integral with, or secured to, the motor frames.

5.17.4 Ignition System:

5.17.4.1 When automatic electric ignition is provided, it shall be accomplished by means of either a high-voltage electric spark, a high-energy electric spark, or a glow coil.
5.17.4.2 Ignition transformers shall conform to requirements of the UL Standard 506.

5.17.4.3 Ignition cable shall conform to requirements of the UL Standard 814.

5.17.5 Wiring:

5.17.5.1 All wiring for incinerators shall be rated for the maximum operating temperature to which it may be exposed. Such wiring shall be in accordance with ANSI/NFPA No. 70. All wiring between components shall have copper conductors and be constructed in accordance with the ANSI/NFPA No. 70.

5.17.5.2 All electrical wiring shall have a voltage rating commensurate with the voltage of the power supply.

5.17.5.3 Conductors shall be protected from physical damage where appropriate.

5.17.5.4 Conductors shall be sized on the basis of the rated current of the load they supply.

5.17.6 Bonding and Grounding:

5.17.6.1 Means shall be provided for grounding the major metallic frame or assembly of the incinerators.

5.17.6.2 Noncurrent carrying enclosures, frames, and similar parts of all electrical components and devices shall be bonded to the main frame or assembly of the boiler. Electrical components that are bonded by their installation do not require a separate bonding conductor.

5.17.6.3 When an insulated conductor is used to bond electrical components and devices, it shall show a continuous green color, with or without a yellow stripe.

6. Operating Requirements

6.1 The incinerator system shall be designed and constructed for operation with the following conditions:

- Maximum combustion chamber temperature: 1200°C (2150°F)
- Minimum combustion chamber temperature: 850°C (1560°F)
- Preheat temperature of combustion chamber: 650°C (1200°F)

For batch-loaded incinerators, there are no preheating requirements. However, the incinerator shall be so designed that the temperature in the actual combustion space shall reach 600°C (1110°F) within 5 min after start.

Prepurge, before ignition: at least 4 air changes in the chamber(s) and stack, but not less than 15 s

Time between restarts: at least 4 air changes in the chamber(s) and stack, but not less than 15 s

Postpurge, after shutoff of fuel oil: not less than 15 s after the closing of the fuel oil valve

6.2 Incinerating systems are to be operated with underpressure (negative pressure) in the combustion chamber such that no gases or smoke can leak out to the surrounding areas.

6.3 The incinerator shall have warning plates attached in a prominent location on the unit, warning against unauthorized opening of doors to combustion chamber(s) during operation and against overloading the incinerator with waste.

6.4 The incinerator shall have instruction plate(s) attached in a prominent location on the unit that clearly addresses the following:

6.4.1 Cleaning ashes and slag from the combustion chamber(s) and cleaning of combustion air openings before starting the incinerator (where applicable).

6.4.2 Operating procedures and instructions. These shall include system diagrams (combustion/cooling air, fuel, electrical, and waste processing), and procedures for proper start-up, normal operation, normal shutdown, and emergency shutdown.

6.5 To avoid the buildup of dioxins, the flue gas should be shock cooled to a maximum 350°C (660°F) within 2.5 m from the combustion chamber flue gas outlet.

7. Operating Controls

7.1 The entire unit shall be disconnected from all sources of electricity by means of one disconnect switch located near the incinerator (see 5.17.1.1).

7.2 There shall be an emergency stop switch located outside the compartment that stops all power to the equipment. The emergency stop switch shall also be able to stop all power to the fuel pumps. If the incinerator is equipped with an induced draft fan, the fan shall be capable of being restarted independently of the other equipment on the incinerator.

7.3 The control equipment shall be so designed that any failure of the following equipment will prevent continued operations and cause the fuel supply to be cut off.

7.3.1 Safety Thermostat/Draft Failure:

7.3.1.1 A flue gas temperature controller, with a sensor placed in the flue gas duct, shall be provided that will shut down the burner if the flue gas temperature exceeds the temperature set by the manufacturer for the specific design.

7.3.1.2 A combustion temperature controller, with a sensor placed in the combustion chamber, shall be provided that will shut down the burner if the combustion chamber temperature exceeds the maximum temperature.

7.3.1.3 A negative pressure switch shall be provided to monitor the draft and the negative pressure in the combustion chamber. The purpose of this negative pressure switch is to ensure that there is sufficient draft in the incinerator during operations. The circuit to the program relay for the burner shall be opened and an alarm activated before the negative pressure rises to atmospheric pressure. This is applicable to incinerators fitted with induced draft fans.

7.3.2 Flame Failure/Fuel Oil Pressure:

7.3.2.1 The incinerator shall have a flame safeguard control consisting of a flame-sensing element and associated equipment for shutdown of the unit in the event of ignition failure and flame failure during the firing cycle. The flame safeguard control shall be so designed that the failure of any component will cause a safety shutdown and prevent automatic restarting.

7.3.2.2 The flame safeguard control shall be capable of closing the fuel valves in not more than 4 s after a flame failure.

7.3.2.3 The flame safeguard control shall provide a trial-for-ignition period of not more than 10 s during which fuel may be supplied to establish flame. If flame is not established within 10 s, the fuel supply to the burners shall be immediately shut off automatically. Where a light oil pilot is used, the flame safeguard control shall provide a trial-for-ignition period for the pilot of not more than 10 s. If flame is not established within 10 s, the fuel supply to the pilot shall be immediately shut off automatically.

7.3.2.4 Whenever the flame safeguard control has operated because of failure of ignition, flame failure, or failure of any...
component, manual reset of the flame safeguard control shall be required for restart.

7.3.2.5 Flame safeguard controls of the thermostatic type, such as stack switches and pyrostats operated by means of an open bimetallic helix, are prohibited.

7.3.2.6 If fuel oil pressure drops below that set by the manufacturer, a failure and lockout of the program relay shall result. This also applies to a sludge oil used as a fuel. (Applies where pressure is important for the combustion process or where a pump is not an integral part of the burner.)

7.3.3 Motor Overload—All motors shall be protected in all phases by a thermal overload relay or circuit breaker with thermal overload protection that must be reset manually (see 5.17.3.3).

7.4 If there is a loss of power to the incinerator control/alarm panel (not remote alarm panel), the system shall shut down.

7.5 Fuel Supply—Two fuel control solenoid valves shall be provided in series in the fuel supply line to each burner. On multiple burner units, a valve on the main fuel supply line and a valve at each burner will satisfy this requirement. The valves shall be connected electrically in parallel so that both operate simultaneously.

7.6 After shutdown of the oil burner, the exhaust fan or ejector must continue to run until the fire box has cooled sufficiently. This does not apply in the case of an emergency manual trip.

8. Other Requirements

8.1 Documentation—A complete instruction and maintenance manual with drawings, electric diagrams, spare parts list, and so forth shall be furnished with each incinerator.

8.2 Installation—All devices and components shall, as fitted in the ship, be designed to operate when the ship is upright and when inclined at any angle of list up to and including 15° either way under static conditions and 22.5° under dynamic conditions (rolling) either way and simultaneously inclined dynamically (pitching) 7.5° by bow or stern.

8.3 Incinerator:

8.3.1 Incinerators are to be fitted with a pilot burner or spark ignition with sufficient energy to ensure a safe ignition and combustion. The combustion is to take place at sufficient negative pressure in the combustion chamber(s) to ensure no gases or smoke leaking out to the surrounding areas (see 7.3.1.3).

8.3.2 A drip tray is to be fitted under each burner and under any pumps, strainers, and so forth that require occasional examination.

9. Test Methods

9.1 Prototype Test Methods—An operating test method for the prototype of each design shall be conducted, with a test report completed indicating results of all test methods. The test methods shall be conducted to ensure that all of the control components have been properly installed and that all parts of the incinerator, including controls and safety devices, are in satisfactory operating condition. Test methods shall include those described in 9.3.

9.2 Factory Test Methods—For each unit, if preassembled, an operating test method shall be conducted to ensure that all of the control components have been properly installed and that all parts of the incinerator, including controls and safety devices, are in satisfactory operating condition. The requirements for prepurge and time between restarts referred to in 6.1 shall be verified at the time of the installation test method.

9.3 Installation Test Methods—An operating test method after installation shall be conducted to ensure that all of the control components have been properly installed and that all parts of the incinerator, including controls and safety devices, are in satisfactory operating condition. The requirements for prepurge and time between restarts referred to in 6.1 shall be verified at the time of the installation test method.

9.3.1 Flame Safeguard—The operation of the flame safeguard system shall be verified by causing flame and ignition failures. Operation of the audible alarm and visible indicator shall be verified. The shutdown times shall be verified.

9.3.2 Limit Controls—Shutdown as a result of the operation of the limit controls shall be verified.

9.3.2.1 Oil Pressure Limit Control—The lowering of the fuel oil pressure below the value required for safe combustion shall initiate a safety shutdown.

9.3.2.2 Air Pressure Limit Control—Systems using compressed air-oil atomization shall be tested to verify that the air pressure is above the minimum required for proper atomization.

9.3.2.3 Other Interlocks—Other interlocks provided shall be tested for proper operation as specified by the unit manufacturer.

9.3.3 Combustion Controls—The combustion control shall be stable and operate smoothly.

9.3.4 Programming Controls—Programming controls shall be verified as controlling and cycling the unit in the intended manner. Proper pre-purge, ignition, post-purge, and modulation shall be verified. A stopwatch shall be used for verifying intervals of time.

9.3.5 Fuel Supply Controls—The satisfactory operation of the two fuel control solenoid valves for all conditions of operation and shutdown shall be verified.

9.3.6 Low-Voltage Test Method—A low-voltage test method shall be conducted on the incinerator unit to demonstrate satisfactorily that the fuel supply to the burners will be automatically shut off before an incinerator malfunction results from the reduced voltage.

9.3.7 Switches—All switches associated with the unit shall be tested to verify proper operation.
10. Inspection

10.1 The manufacturer shall afford the purchaser’s inspector all reasonable facilities necessary to satisfy him that the material is being furnished in accordance with this specification. Inspection by the purchaser shall not interfere unnecessarily with the manufacturer’s operations. All examinations and inspections shall be made at the place of manufacture, unless otherwise agreed upon.

11. Certification

11.1 Manufacturer’s certification that an incinerator has been constructed in accordance with this specification shall be provided (by letter or certificate).

12. Product Marking

12.1 Each incinerator shall be permanently marked indicating the following:

12.1.1 Manufacturer’s name or trademark.

12.1.2 Style, type, model, or other manufacturer’s designation for the incinerator.

12.1.3 Capacity to be indicated by net designed heat release of the incinerator in heat units per timed period; for example, British thermal units per hour, megajoules per hour, or kilocalories per hour.

12.1.4 ASTM designation of this specification (F 1323).

12.1.5 IMO certification, if required.

12.1.6 Other applicable nonmandatory requirements.

13. Quality Assurance

13.1 Incinerators shall be designed, manufactured, and tested in a manner that ensures they meet the requirements of this specification.

13.2 The incinerator manufacturer shall maintain the production quality of the incinerators that are designed, tested, and marked in accordance with this specification. At no time shall an incinerator be sold with this specification designation that does not meet the requirements herein (see Certification).

14. Keywords

14.1 incinerators; shipboard wastes; ships

SUPPLEMENTARY REQUIREMENTS

S1. For U.S. Government Procurement Only

S1.1 Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein. Except as otherwise specified in the contract, the contractor may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

S2. Referenced Documents

MIL-STD-882 System Safety Program Requirements
MIL-STD-901C Grade B Shock Requirements for Shock Tests, Shipboard Machinery, Equipment, and Systems
SNAME T&R Bulletin No. 3-37 Design Guide for Shipboard Airborne Noise Control

S3. Design Considerations

S3.1 The services that are available for the incinerator are as follows:

S3.1.1 440-V, 60-Hz, three-phase electrical power.

S3.1.2 Seawater—at 690 to 1206 kPa (100 to 175 psig) (actual value will vary over time and depending on shipboard location).

S3.1.3 Fresh Water—414 kPa (60 psig) up to 3.8 LPM (10 GPM); 21°C (70°F).

S3.1.4 Ship Service Compressed Air—at 862 kPa (125 psig) (air supply to the space at a maximum temperature of 32°C (90°F) with a wet bulb temperature of 27°C (81°F).

S3.1.5 Aviation Turbine Fuel Oil—Marine diesel, JP-5, or NATO designation F-44.

S3.1.6 Compartment Ventilation—As required.

S4. Materials and Manufacture

S4.1 Refractory material shall have a life expectancy of at least three years (see also 5.8).

S5. Operational Requirements

S5.1 To avoid building up of dioxins, the flue gas shall be shock-cooled to a maximum of 200°C (390°F) within 2.5 m (8.2 ft) from the combustion chamber flue gas outlet. (Replaces 6.5).

S5.2 The shock cooling subsystem shall also neutralize acidic gases to a pH of not less than 5.0 and sufficiently reduce the relative humidity to ensure that condensation will not occur in the exhaust stack or at the stack exhaust point.

S5.3 Stack emissions shall be measured including, but not limited to, carbon monoxide, oxygen, and smoke opacity.

S5.4 The incinerator shall have an internal pressure no greater than 125 Pa (0.018 psi) below ambient pressure for all rates of operation.

S5.5 The system shall not exhibit a visible steam plume from the output stack at 0°C (32°F) ambient. The stack shall operate without the emission of visible sparks or fly ash particles from the exhaust gas outlet.

7 Available from the Naval Publications and Forms Center, 5801 Tabor Ave., Philadelphia, PA 19120.
8 Available from the Society of Naval and Marine Engineers, 601 Pavonia Ave., Jersey City, NJ 07306.
S5.6 A method for evacuation of any smoke or combustible gases entering the charging lock while the trash is transferred into the combustion chamber shall be provided.

S5.7 The reliability and maintainability characteristics of the thermal destruction system shall be such to ensure that the crew of a ship can, with a high degree of confidence, consistently dispose of the waste stream as defined by purchaser. The system shall be designed for an operational life at least ten years.

S5.8 Routine cleaning and preventive maintenance shall not require more than 1 h per day. The design of all components shall be consistent with an at-sea working environment. The incinerator shall have an operational availability \(A_o\) of not less than 0.90 over a six-month operating profile.

S5.9 For organizational level corrective maintenance, the incinerator shall have a geometric mean time to repair (MTTR\(_g\)) of less than 4 h 95% of the time and a maximum repair time (\(M_{\text{max}}\)) of less than 12 h 95% of the time. Repair times do not include the time required to cool down or heat up the incinerator. Organizational maintenance shall include any maintenance required during ship deployments, which are up to six months in duration. Organizational maintenance shall not require skills beyond that which is expected of an enlisted sailor with a twelfth-grade level of education. All other maintenance required to maintain the incinerator functioning for the six-year life expectancy shall be performed by an intermediate level maintenance organization. Intermediate level maintenance is to be performed by trained government repair specialists or contractors and is to include the replacement of refractory material and any other major maintenance required to ensure safe and reliable operation for a six-month deployment.

S5.10 Airborne noise shall meet the noise limits recommended in SNAME T&R Bulletin No. 3-37 that provides design guidance on shipboard airborne noise control.

S5.11 The system shall be free from vibration that could result in damage or the potential of damage to the ship structure, machinery, equipment, and systems, or interferes with the operation of the ship, its cargo systems, or any ship component. It shall have no resonant frequencies of its parts or structure below 40 Hz. The system shall be in accordance with MIL-STD-901C for Grade B shock.

S5.12 The incinerator shall be safe under both normal and unplanned conditions in accordance with the requirements of MIL-STD-882. As part of this study, a Failure Modes and Effects Criticality Analysis shall be performed to evaluate the impact and likelihood of all conceivable failures. This shall include as a minimum, accidental introduction of materials that are not recommended for processing and loss of any or all services.

S5.12.1 The following types of failures are not acceptable as part of the incinerator:

S5.12.1.1 Catastrophic failures that result in death or system loss and are of remote likelihood to occur.

S5.12.1.2 Critical failures that cause severe injury, illness, or major system damage and are of probable likelihood to occur.

S5.12.1.3 Marginal failures that cause minor injury or illness or system damage and are expected to occur frequently.

S5.12.2 The following failures shall be minimized to the greatest possible extent:

S5.12.2.1 Catastrophic failures that are of improbable likelihood to occur.

S5.12.2.2 Critical failures that are of occasional likelihood to occur.

S5.12.2.3 Marginal failures that are of probable likelihood to occur.

APPENDIXES

X1. LOCATION REQUIREMENTS FOR INCINERATORS

X1.1 Incinerators for sludge oil may be installed in the engine room or in a separate room. Incinerators for garbage installed in the engine room should receive due attention to size and location of the incinerator. If the incinerator is installed in a separate room outside the engine room, bulkheads and decks of this room are to be A-class boundaries insulated in accordance with the requirements for Category A machinery spaces, as defined by SOLAS 1974, as amended in Chapter II-2, Regulation 3. This requirement shall apply regardless of the type of vessel construction used (that is, Methods IC, IIC, IIIC as defined in SOLAS II-2, Regulation 42) and regardless of whether the vessel is required to meet SOLAS or to be approved or certified by the cognizant government authority.

X1.2 On certified vessels or those meeting SOLAS, both fire-detection and extinguishing systems must be approved by the cognizant government authority. Ventilation ducts should be capable of being closed by means of fire dampers, controlled from outside the incinerator room, of sufficient construction to maintain the A-class boundary. Emergency stop of oil burner and oil-booster pumps shall also be arranged outside the room.

X1.3 Flue gas-uptakes and surfaces of incinerators are not to be less than 500 mm (20 in.) from fuel, oil tanks, or accommodation bulkheads. Flue gas-uptake and exhaust pipe are to be insulated and located well away from electrical
installations and inflammable items. Exhaust pipes in the casing are to be led to the top of the funnel. Exhaust uptakes from incinerators, which are installed in separate rooms outside the engine room, are to be approved in each case.

X1.4 Incinerators and flue gas uptakes are to be located outside of hazardous areas as defined by the applicable rules.

X1.5 The flue lines of incinerating systems shall not open into the flues or exhaust lines of other equipment but must be arranged separately to the point of discharge.

X1.6 Garbage chutes shall comply with the same fire standards as incinerator rooms outside engine rooms.

**X2. INCINERATORS INTEGRATED WITH HEAT RECOVERY UNITS**

X2.1 The flue gas system, for incinerators in which the flue gas is led through a heat recovery unit (economizer), should be designed so that the incinerator can continue operation with the economizer coils dry. This may be accomplished with bypass dampers if needed.

X2.2 The incinerator unit should be equipped with a visual and audible alarm in case of loss of feed water.

X2.3 The gas side of the economizer should have equipment for proper cleaning. Sufficient access should be provided for adequate inspection of external heating surfaces.

**X3. FLUE GAS TEMPERATURE**

X3.1 When deciding upon the type of incinerator, consideration should be given as to what the flue gas temperature will be. The flue gas temperature can be a determining factor in the selection of materials for fabricating the stack. Special high-temperature material may be required for use in fabricating the stack when the flue gas temperatures exceed 413°C (775°F).

**X4. DESIGN FOR FUTURE RETROFITS OF AIR EMISSION CONTROL EQUIPMENT**

X4.1 Though not a requirement, it is recommended that incinerators be provisioned with an ability for future retrofits of air emission control equipment to accommodate emission standards for shipboard incinerators as they are developed.

X4.2 The Environmental Protection Agency (EPA) does not currently have emission standards for small shipboard incinerators as described in this specification. However, the EPA has indicated it intends to publish emission standards eventually. In addition, emission standards for state and local jurisdictions vary.

**X5. SPARK ARRESTORS**

X5.1 The incinerator should be so constructed or so equipped as not to permit from the exhaust the passage of spherical objects having a diameter larger than 13.7 mm (½ in.) nor block the passage of spherical objects having a diameter of less than 9.5 mm (⅜ in.).

X5.2 Means should be provided for securely attaching the spark arrestors to chimneys to provide adequate support and prevent movement of the arrestor.

X5.3 Means should be provided to replace spark screens.

**X6. HUMAN ENGINEERING**

X6.1 The system should comply with Practice F 1166.

X6.2 The incinerator should conform to human engineering principles to the degree that it can be operated and maintained by a 152-cm (5-ft) tall person as well as a 185-cm (6-ft 1-in.) tall person.

X6.3 Its design should also reflect system and personnel safety factors, including the elimination or minimization of the potential for human error during operation and maintenance, under both routine and nonroutine or emergency conditions. Machinery, systems, equipment, and fixtures should be intrinsically safe as far as practicable, and in the event of failure, should fail to a safe mode.

X6.4 Man-machine interfaces should minimize both the potential for and the consequence of human error.

X6.5 The level of training required for operating personnel should be no more than 2 h of on-the-job training; training required for maintenance personnel should be no more than 5 h.
X7. ASH/SLAG COLLECTION

X7.1 The incinerator should provide for the safe collection and removal of both bottom and fly ash from the incinerator with minimal interference to the combustion process. The incidental introduction of metal or glass into the incinerator should not negatively impact incinerator operation, maintenance, or the ash removal processes.

X7.2 The process for the collection and removal of bottom and fly ash or slag can be either of the following: (1) automatic and continuous without requiring shutdown or (2) manual and require system shutdown. In either case, operator handling of ash should be required to occur no more than once per day.

X7.3 For automatic ash removal systems, the ASTM interlock requirements to prevent ash removal until the combustion chamber cools to 220°C (428°F) is hereby waived, provided the automated ash removal process does not create hazardous or unsafe conditions and the combustion zone is isolated from the outside work space at all times.

X7.4 The incinerator architecture should not require undue exposure of the operator to temperatures above 60°C (140°F), ash, hazardous gases, or other incinerator by-products during the process of transferring ash or slag into a container for storage or disposal.

X7.5 The ash or slag will be transferred to and stored in 55-gal drums or other size containers dependent on type and size of incinerator and size of ship it is installed upon. The temperature of the ash being transferred should be less than 220°C (428°F).

X7.6 There should be no obstructions around the ash removal door that can cause accidental exposure of maintenance personnel to ash either directly or through the air.

X8. PROCESS MONITORING

X8.1 The system should provide for sufficient process monitoring and the automated controls necessary to maintain the set point operating conditions.

X8.2 Set points for low/high temperature, carbon monoxide, oxygen, smoke opacity, and any other parameter required by the manufacturer to control the incineration process are to be determined by the manufacturer.

X8.3 The incinerator control/operator interface should clearly communicate all information to the operator that is required to ensure efficient and safe operation of the incinerator process.

X9. EMISSION REQUIREMENTS FOR SHIPBOARD INCINERATORS

X9.1 An IMO Type Approval Certificate should be required for each shipboard incinerator. To obtain such certificate, the incinerator should be designed and built to an IMO-approved standard. Each model should go through a specified type approval test operation at the factory or an approved test facility, and under the responsibility of the administration.

X9.2 The Type Approval Test should include measuring of the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Unit or Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum capacity</td>
<td>kW or kcal/h</td>
</tr>
<tr>
<td>Pilot fuel consumption</td>
<td>kg/h of specified waste</td>
</tr>
<tr>
<td>O₂ average in combustion chamber/zone</td>
<td>kg/h per burner</td>
</tr>
<tr>
<td>CO average in flue gas</td>
<td>%</td>
</tr>
<tr>
<td>Soot number average</td>
<td>mg/MJ</td>
</tr>
<tr>
<td>Combustion chamber flue gas outlet temperature average</td>
<td>Bacharach or Ringelman Scale</td>
</tr>
<tr>
<td>Amount of unburned components in ashes</td>
<td>°C</td>
</tr>
<tr>
<td>% by weight</td>
<td></td>
</tr>
</tbody>
</table>

X9.3 Duration of Test Operation:

For sludge oil and solid waste burning 6 to 8 h

X9.4 Fuel/Waste Specification for Type Approval Test (% by Weight):

<table>
<thead>
<tr>
<th>Sludge oil consisting of:</th>
</tr>
</thead>
<tbody>
<tr>
<td>75 % sludge oil from heavy fuel oil</td>
</tr>
<tr>
<td>5 % waste lubricating oil</td>
</tr>
<tr>
<td>20 % emulsified water</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Solid waste (Class 2) consisting of:</th>
</tr>
</thead>
<tbody>
<tr>
<td>50 % food waste</td>
</tr>
<tr>
<td>50 % rubbish containing approximately 30 % paper, 40 % cardboard, 10 % rags, and 20 % plastic. This mixture will have up to 50 % moisture and 7 % incombustible solids.</td>
</tr>
</tbody>
</table>

Classes of Waste:

Class 0 Trash, a mixture of highly combustible waste such as paper, cardboard, wood boxes, and combustible floor sweepings, with up to 10 % by weight of plastic bags, coated paper, laminated paper, treated corrugated cardboard, oil rags, and plastic or rubber scraps. This type of waste contains up to 10 % moisture, 5 % incombustible solids, and has a heating value of about 19 700 kJ/kg as fired.

Class 1 Rubbish, a mixture of combustible waste such as paper, cardboard, cartons, wood scrap, foliage, and combustible floor sweepings. The mixture contains up to 20 % by weight of galley or cafeteria waste, but contains little or no treated papers, plastic, or rubber wastes. This type of waste contains 25 % moisture, 10 % incombustible solids, and has a heating value of about 15 100 kJ/kg as fired.
Class 2  Refuse, consisting of approximately even mixture of rubbish and garbage by weight. This type waste is common to passenger ships’ occupancy, consisting of up to 50 % moisture, 7 % incombustible solids, and has a heating value of about 10 000 kJ/kg as fired.

Class 3  Garbage, consisting of animal and vegetable wastes from restaurants, cafeterias, galleys, sick bay, and like installations. This type of waste contains up to 70 % moisture, up to 5 % incombustible solids, and has a heating value range from about 2300 kJ/kg as fired.

Class 4  Aquatic life forms and animal remains, consisting of carcasses, organs, and solid organic wastes from vessels carrying animal-type cargo, consisting of up to 85 % moisture, 5 % incombustible solids, and having a heating value range from about 2300 kJ/kg as fired.

Class 5  By-product waste, liquid or semiliquid, such as tar, paints, solvents, sludge, oil, waste oil, and so forth, from shipboard operations. The Btu values must be determined by the individual materials to be destroyed.

Class 6  Solid by-product waste, such as rubber, plastics, wood waste, and so forth, from industrial operations. The Btu values must be determined by the individual materials to be destroyed.

Density of loose general waste generated on board ship will be about 130 kg/m³.

Reference: Waste classification from Incinerator Institute of America.

X9.5  Required Emission Standards to be Verified by Type Approval Test:

- O₂ in combustion chamber 6 to 12 %
- CO in flue gas maximum average 200 mg/MJ
- Soot number maximum average Bacharach 3 or Ringelman 1
- Unburned components in ash residues maximum 10 % by weight
- Combustion chamber flue gas outlet temperature range 850–1 200°C

A high temperature in the actual combustion chamber/zone is an absolute requirement to obtain a complete and smoke-free incineration, including that of plastic and other synthetic materials while minimizing dioxin, VOC (volatile organic compounds), and emissions.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

1. Scope

1.1 This guide covers metallic abrasive blasting to descale the interior of carbon steel pipe.

1.2 This guide is recommended for use in conjunction with an abrasive reclamation system.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2.3 Other Documents:
SSPC SP10 Surface Preparation Specifications
SSFS 20-66 Standard Specification for Cast Steel Abrasives

3. Significance and Use

3.1 The maximum length and minimum diameter of the pipe shall be determined by the capacity of the blast equipment used.

3.2 This guide is recommended for removing mill scale, rust scale, paints, zins, and oxides.

4. General Requirements

4.1 Before blasting, pipe shall be dry and free of slag and weld spatter which would not be removed by abrasive blasting. Pipe shall also be free of loose dust and debris which might hamper the effectiveness of abrasive blasting.

4.2 Abrasive blasting shall be accomplished in a dry area with the ambient air condition such that condensation does not occur.

4.3 Shot and blasting equipment shall be stored at a temperature not less than −13°C (10°F) above the dew point of the surrounding area.

4.3.1 Abrasive reclamation system shall include a filtration system capable of removing oxides, debris, dust, shot/grit fragments, and fines.

4.4 Compressed air system shall be equipped with moisture removal devices capable of reducing the dew point of the air at the nozzle to −18°C (approximately 0°F) or less.

4.5 Hoses shall have the maximum practical diameter and shall be as short as possible.

4.6 Nozzles shall have the maximum possible aperture as determined by the capacity of the blast equipment and as limited by the pipe diameter.

4.7 Internal pipe cleaning nozzle assemblies are commercially available and shall be used where required.

4.7.1 Internal pipe cleaning nozzle assemblies shall include a carriage which is capable of centering the nozzle concentrically in the pipe being blasted and a nozzle which is capable of producing a consistent 360° blast pattern.

4.7.2 Diagrams of some commercially available internal pipe cleaning assemblies are provided in Figs. 1-4.

4.7.3 If a lance is required, it shall be at least as long as the pipe being blasted.

4.8 Blasting shall be accomplished using an abrasive mixture of cast steel shot and grit, or with iron shot or grit.

4.8.1 Iron or grit may be used if desired.

4.8.2 Cast steel shot and grit mixtures shall be sized in accordance with SAE J444.

4.8.3 Reclaimed shot and grit shall be of the same quality as the original material.
4.9 Cast steel shot shall be manufactured in accordance with SAE J827 and tempered to a hardness of 40-50 Rockwell C in accordance with Test Methods E 18 (see Table 1).

4.10 Cast steel grit shall be manufactured in accordance with SFSA 20-66 and tempered to a hardness of 55-65 Rockwell C in accordance with Test Methods E 18 (see Table 2).

4.11 Shot and grit size shall be determined by the following criteria:

4.11.1 Smaller shot and grit produces more impacts per inch and is therefore more effective for removing paints and corrosion products.

4.11.2 Larger shot and grit produces more kinetic energy per impact and is therefore more efficient for removing heavier deposits such as mill scale.

4.12 If surface type and profile is specified, abrasive shall be selected using the following criteria:

4.12.1 Shot produces a wavy rounded surface profile which increases coating area coverage.

4.12.2 Grit produces a sharp angular profile which forms a better anchor pattern for most coatings.

4.12.3 Table 3 lists some typical maximum profiles produced by some commercial abrasive media.\(^5\)

4.13 Blasting shall be accomplished with a minimum of 620-kPa (90-psi) dry air pressure at the nozzle.

\(^B\)It is extremely important that contractual documents which specify abrasive to be used clearly designate the abrasive by size and by hardness.

\(^C\)Both cast steel shot and grit of hardmesses in the range from 30 to 66 Rockwell C may be purchased. However, the abrasives of less than 40 RC and greater than 60 RC are generally used for applications other than surface preparation of structural steel.

\(^D\)Abrasive manufacturers identify steel grit by designations which include two or more prefix letters, followed by the number size. Prefix letters are different for each of the abrasive suppliers for any given hardness range.

\(^D\)Size Range refers to working mix (operating mix) for recirculating abrasive blast systems. For additional information see Vol 1, Chapter 2 of the “Steel Structures Painting Manual.”
4.14 If an abrasive reclamation system is used, it shall be capable of filtering the used abrasive and returning the usable mixture.

5. Procedure

5.1 Pipe shall be located as close as possible to the blast equipment and blown clean of loose debris before blasting.

5.2 Pipe with an interior diameter of 100 mm (approximately 4 in.) or larger may be manually blasted from both ends if both ends are accessible and the pipe length configuration and equipment capabilities are such that the blasted surface is consistent throughout the pipe.

5.3 If pipe is inaccessible from one end, bent, or too long to be hand blasted, it will be necessary to use an internal pipe cleaning nozzle assembly.

5.3.1 Nozzle assembly shall be placed inside the pipe in a manner such that the nozzle is concentric with the pipe.

5.3.2 Nozzle assembly shall then be passed through the entire length of the pipe at a constant rate.

5.4 Extreme caution shall be used in all the blasting operations to avoid unnecessary removal of parent metal.

5.5 When blasting is completed, pipe shall be blown clean of residual debris and visually inspected in accordance with Standard D 2200 and reblasted as required.

5.6 Interior of pipe shall then be coated when specified. Coatings should be applied to freshly blasted surface before any rusting or contamination should occur.

6. Workmanship, Finish, and Appearance

6.1 Pipe shall be blasted to a near white finish in accordance with SSPC SP10, or as otherwise specified.

7. Keywords

7.1 abrasive blasting; carbon steel pipe; descaling; interior descaling; marine technology; metallic abrasive; pipe descaling; ships

Profile heights shown for steel abrasives were produced with conditioned abrasives of stabilized operating mixes in recirculating abrasive blast cleaning machine. Profile heights produced by new abrasives having screen analyses shown in SAE J444 will be appreciably higher.

Cast steel shot: Hardness 40 to 50 Rockwell C.

Cast steel grit: Hardness 55 to 60 Rockwell C.
Standard Practice for Installation Procedures of Vinyl Deck Coverings on Portable Plates in Electrical and Electronic Spaces

1. Scope

1.1 This practice covers the acceptable method for installing insulated deck covering on portable deck plates.
1.2 This deck covering shall be installed, in way of the electrical and electronic spaces, for marine use.
1.3 The values stated in SI (metric) units are to be regarded as the standard. The values in parentheses are for information only.
1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:
   D 1338 Practice for Working Life of Liquid or Paste Adhesives by Consistency and Bond Strength
   D 2393 Test Method for Viscosity of Epoxy Resins and Related Components
   D 4389 Specification for Finished Glass Fabrics Woven from Rovings
   F 150 Test Method for Electrical Resistance of Conductive and Static Dissipative Resilient Flooring

2.2 Other Documents:
   Steel Structural Painting Council  SP-11

3. Requirements

3.1 Operations Area—Typical areas for application of the electric insulating deck covering are:
3.1.1 The operating areas in front and rear of power and lighting switchboards, interior-communication switchboards, test switchboards, fire-control switchboards, and shipboard announcing-systems amplifiers and control panels.
3.1.2 The area around electronic equipment which may be contacted by personnel in servicing or tuning energized equipment.
3.1.3 Vinyl sheets should be confined to the minimum deck areas (generally 0.9 m (3 ft) wide) surrounding the apparatus necessary to prevent electric shock, and should, unless otherwise specified, be cemented to the deck in lieu of other specified deck coverings.

3.2 Installation—Vinyl Sheets:
3.2.1 Installation of deck covering shall be in accordance with Figs. 1-7, using vinyl sheet and fiberglass binding strips (see Fig. 1 and Fig. 5).

3.2.2 Vinyl sheets and fiberglass sheets shall be united at the edges in a rabbet joint as shown (see Fig. 7), and such that the fiberglass overlaps at all joints. All rabbeted surfaces shall be smooth and corners sharp and square, such that at installation the overlapping areas fit firmly and flush. Vinyl shall meet requirements and tests provided in Test Method F 150.

3.3 **Adhesive:**

3.3.1 Vinyl sheets shall be secured to each portable plate with adhesive. Adhesive should not extend beyond edges of vinyl sheet.

3.3.2 Silicone compound, with 1% liquid catalyst, should be applied between lapping areas in accordance with Test Method D 1338.

3.4 **Fiberglass**—Glass fiber base, epoxy resin sheets furnished under this specification (Fig. 1 and Fig. 5), shall be a product consisting of plies or layers of cloth or nonwoven parallel aligned fibers bonded with an epoxy resin compound, in accordance with Specification D 4389.

3.5 **Fastening with Nylon Screws**—Fiberglass binding strips shall be secured to the deck with nylon screws. A 76-mm (3-in.) wide strip over joints between portable plates shall be fastened with a double row of screws. A 38-mm (1½-in.) wide strip or shape to suit at deck edges shall be fastened with a single row of screws, spacing between screws not to exceed 127 mm (5 in.) center-to-center and located to clear deck plate screws. (See Fig. 7.)

3.6 **Exposed Areas Treated with Epoxy:**

3.6.1 Before the epoxy is applied, the surface to be covered should be (a) cleaned with a solvent, and (b) further treated in accordance with Steel Structural Painting Council SP-11.

3.6.2 Epoxy resin shall be applied to the exposed vertical lip of deck edges on stanchions, to approximately 305 mm (12 in.) above deck, after all other deck covering work has been
completed. Application of epoxy shall be by brush to approximately 1.5-mm (1/16-in.) thickness, and in accordance with Test Method D 2393. (For location of epoxy to be applied, see Fig. 3 and Fig. 4.)

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Practice for
Use of SI (Metric) Units in Maritime Applications (Committee F-25 Supplement to IEEE/ASTM SI 10)1

INTRODUCTION

The International System of Units (SI) was developed by the General Conference on Weights and Measures (CGPM), which is an international treaty organization. The abbreviation SI, derived from the French “Le Système International d’Unités,” is used in all languages.

On Dec. 23, 1975, Public Law 94-168, “The Metric Conversion Act of 1975,” was signed by President Ford, committing the United States to a coordinated voluntary conversion to the metric system of measurement. The Act specifically defines the “metric system of measurement” as “the International System of Units as established by the General Conference on Weights and Measures in 1960, and as interpreted or modified for the United States by the Secretary of Commerce.”

On Aug. 23, 1988, President Reagan signed into law P.L. 100-576, the Omnibus Trade and Competitiveness Act of 1988. The Act specifies that “metric” means the modernized metric system (SI). The Act then amended the Metric Conversion Act of 1975 to designate the metric system of measurement as the preferred system of weights and measures for United States trade and commerce.

This practice will help obtain uniform SI practice in the marine industry by providing a technical reference for the International System of Units (SI). The practice is not intended to cover all aspects of SI usage, but to serve as a ready reference especially tailored to the operating needs of the industry. For further information on SI usage and conversion factors for units not found herein, refer to IEEE/ASTM SI 10, upon which this practice is based.2 In the event of a conflict, IEEE/ASTM SI 10 shall take precedence. (See also NIST Special Publication 811.)3 Hardware and other standards in SI are currently being developed.

1. Scope

1.1 This practice covers the use of SI, which is comprised of base and derived SI units. Also discussed are non-SI units that have been accepted and recognized by the CGPM as appropriate for limited use or time. Basic rules for style and usage of SI are set forth, as well as methods for conversion from non-SI units to SI units. Tables of quantities used by the marine industry are included, with present units and conversion factors given.

2. Referenced Documents

2.1 ASTM Standards:

2.2 NIST Publications:
NIST Special Publication 811 Guide for the Use of the International System of Units (SI)3
NIST Special Publication 330 The International System of Units (SI)3

3. Terminology

3.1 Definitions:

3.1.1 quantity, n—measurable attribute of a physical phenomenon.

3.1.2 SI, n—The universally accepted abbreviation for the International System of Units as defined in the document Le Système International d’Unités, 6th Edition, published by the International Bureau of Weights and Measures (BIPM), Sevres, France, 1991, and as interpreted and modified for the United...
3.1.3 unit, n—reference value of a given quantity as defined by CGPM Resolution or ISO standards. There is only one unit for each quantity in SI.

3.2 Definitions of Terms Specific to This Standard:
3.2.1 coherent system of units—a system of units of measurement in which a small number of base units, defined as dimensionally independent, are used to derive all other units in the system by rules of multiplication and division with no numerical factors other than unity.

4. The Concept of SI
4.1 The International System of Units (SI) was developed to provide a universal, coherent, and preferred system of units for world-wide use and appropriate to the needs of modern science, technology, and international commerce.

4.2 The principal features of SI are:
4.2.1 There is one and only one unit for each quantity.
4.2.2 The system is fully coherent.
4.2.3 Designated prefixes can be attached to units to form multiples and submultiples of ten raised to a power. Use of the prefixes provides for convenient numerical values when the magnitude of a quantity is stated, and avoids the need for many insignificant zeroes. The system is decimal, the same as the commonly used numerical system.
4.2.4 Units and prefixes are represented by standardized and internationally recognized symbols.
4.2.5 A few specifically accepted non-SI units are permitted in conjunction with SI.
4.4 SI units, acceptable non-SI units, and prefixes are discussed in Sections 5 and 6.

5. SI Units
5.1 SI includes two classes of units:
5.1.1 Base units and
5.1.2 Derived units.
5.2 Base Units—The International System of Units is based on seven base units, listed in Table 1, which by convention are regarded as dimensionally independent.
5.3 Derived Units—Derived units are formed by the algebraic combination of base units and derived units. Derived units with special names are listed in Table 2.
5.4 Temperature—The SI unit of thermodynamic temperature is the kelvin, and this unit is properly used for expressing thermodynamic temperature and temperature intervals. The thermodynamic temperature and temperature intervals. The

degree Celsius is equivalent to kelvin with a different zero point on the scale. Celsius temperature  is equal to kelvin temperature minus 273.15 ( = T − T₀, where T = Kelvin and T₀ = 273.15).

5.5 SI Prefixes—The prefixes and symbols shown in Table 3 are used to form decimal multiples and submultiples of SI units.

5.6 Selection of Prefixes:
5.6.1 A prefix should be selected so that the numerical value of the unit expressed will fall between 0.1 and 1000. An exception to this rule arises in the preparation of tables of values of the same quantity and in discussion of such values within a given context, when it is better to use the same unit multiple. Also, for certain applications, one particular multiple will customarily be used; for example, use of the millimetre for linear dimensions in engineering drawings.

5.6.2 Compound prefixes should not be used; for example, use GJ, not kMJ.

5.6.3 Prefixes should preferably not be used in the denominator of compound units. Example, use V/m not mV/mm. The exception is the kilogram as it is the base unit: J/kg, not kJ/g.

5.6.4 Errors in calculation may be avoided by using powers of ten with the units rather than prefixes.
6. Non-SI Units in Use with SI

6.1 Units in Use with SI—Certain units that are not SI have been accepted for use with SI units. Some of these units, currently recognized as acceptable for use with SI, are listed in Table 4 and Table 5.

6.2 Time—The SI unit of time is the second. This unit is preferred and should be used when practical, particularly in technical calculations.

6.3 Plane Angle—The SI unit of plane angle is the radian. When the radian is not a convenient unit, the degree should be used with decimal submultiples. Minutes and seconds should be used only when required (as in navigation).

6.4 Area—The SI unit of area is the square metre. The hectare (ha) is a special name for square hectometre (hm²). Large land or water areas are generally expressed in hectares or in square kilometres.

6.5 Volume—The SI unit of volume is the cubic metre. The cubic metre, or one of its multiples or submultiples, is preferred for all applications. The special name litre has been approved by the CGPM for the cubic decimetre.

6.6 Mass—The SI unit of mass is the kilogram. The kilogram, or one of the multiples or submultiples formed by attaching an SI prefix to gram, is preferred for all applications. For large masses (such as have been expressed in tons), the megagram is the appropriate unit. The term metric ton should be restricted to commercial and maritime usage, and no prefixes should be used with it. To avoid confusion, use of the term “tonne” to indicate metric ton is discouraged.

7. Mass, Force, and Weight

7.1 SI, being coherent, is different from the older metric systems in the use of distinctly separate units for mass and force. In SI, the unit of force, the newton (N), is derived as the laws of physics dictate, instead of being related to gravity, and is defined as being equal to the force that imparts an acceleration of unit (1 m/s²) to a unit mass, the kilogram (kg).

7.1.1 Mass—The mass of a body is a measure of its inertia, that is, its resistance to a change in its motion. In practical terms, mass represents the quantity of matter in a body (not to be confused with amount of substance expressed in moles). The SI unit of mass is the kilogram (kg).

7.1.2 Force—Force is the mechanical action on a body resulting from physical contact with another body or the action resulting from gravitational or electromagnetic fields. The SI unit of force is the newton (N).

7.1.3 Weight—The weight W of a body is the effective gravity force acting on it and equals the product of its mass m and the local acceleration of free fall, g, so that W = mg. In SI, weight is measured in newtons (N). Because the acceleration of gravity (the acceleration of free fall) varies slightly over the surface of the earth, the weight of a body varies accordingly, whereas its mass is a constant.

7.1.4 Discussion—The existence of clearly separate units for mass and force in SI contrasts with the widespread use of
the units lb and kg for both mass and force. Whereas the word “weight” has been commonly used when mass is intended or implied, especially in commerce and everyday life, this use should in time disappear with growing acceptance and use of SI units, and the word mass (rather than weight) will be used when mass is meant. The use of weight for mass should be avoided altogether in scientific and technical communication.

8. Rules for Style and Usage of SI

8.1 Rules for Writing Unit Symbols:

8.1.1 Particular care must be taken to use the correct symbols for units and prefixes (for example, K for kelvin, k for kilo, M for mega, m for milli). When using systems with limited character sets, as in Telex transmission or computer printout, the standard symbols cannot be used. For these purposes, refer to ISO 2955 or ANSI X3.50.

8.1.2 Unit symbols are symbols and do not vary from singular to plural.

8.1.3 Unit symbols should be printed in roman (upright) type, regardless of the type style used in the surrounding text.

8.1.4 Unit symbols are not followed by a period except when used at the end of a sentence.

8.1.5 The numerical value associated with a symbol should be separated from that symbol by a space. For example, 25.4 mm, not 25.4mm. The only exception to this rule is that no space is left between the symbols (for example, N·m).

8.1.6 Unit symbols should be used in preference to the unit names except when a number written out in words precedes the unit; for example “seven metres” not “seven m.”

8.2 Rules for Writing Unit Names:

8.2.1 The first letter of a unit name is not capitalized except at the beginning of a sentence or in capitalized material such as a title.

8.2.2 Plurals of unit names are formed in the ordinary manner, except for lux, hertz, and siemens, which remain the same.

8.2.3 No space or hyphen is used between a prefix and the unit name; for example, kilonewton.

8.3 Product, Quotient, and Powers:

8.3.1 To indicate the product of units when using their names, a space is left between the names (for example, newton metre). When using symbols, a centered dot should be placed between the symbols (for example, N·m).

8.3.2 To indicate the quotient of units when using their names use the word “per” (for example, metres per second). When using unit symbols, a solidus (/) or negative exponent should be used (for example, m/s or m·s⁻¹). Do not use more than one solidus in the same expression. Use parentheses to avoid any ambiguity (consider m/s·A can mean m/(s·A) or (m/s)·A).

8.3.3 To indicate powers when using unit names, the words “square,” “cubic,” “squared,” “cubed,” and so forth should be used (for example, square metre, second squared). When using unit symbols, powers are indicated by the use of an exponent (for example, m³).

8.4 Numbers:

8.4.1 At present, the period will be used for the decimal marker. For numbers of less than one, a zero should precede the decimal; for example, 0.964.

8.4.2 Recommended international practice calls for the use of a space to separate large numbers into groups of three. Do not use a comma. The digits should be separated into groups of three counting from the decimal point toward the left and the right, and using a small space to separate the groups. In numbers of four digits, the space is usually not necessary except to provide uniformity in tables, columns, and so forth. For example, 16 390, 1.828 8 or 1.8288, 4 536 or 4536.

9. Conversion and Rounding Methods

9.1 Soft Conversion—Soft conversion is the process of changing the non-SI measurement language to equivalent SI units within acceptable measurement tolerances without changing the physical configuration. In other words, the item described is the same item both before and after conversion.

9.2 Hard Conversion—Hard conversion is the change of design and use of measures to SI as if non-SI units did not exist, namely the use of integers and round numbers, in SI, as the basis of design. Although the term is in general use, it is technically incorrect when applied to specific items because no “conversion” takes place; rather, a new item, designed in SI units (requiring a new identification), is created to replace the old item.

9.3 Conversion Factors—Table 6 contains conversion factors for units commonly used in the marine field.

9.4 Precision—When converting, care must be given to the precision desired. The number of significant digits retained in the answer should be such that accuracy is neither sacrificed nor exaggerated. Specified quantities should first be multiplied by the exact conversion factor and then rounded to the appropriate number of significant digits. Do not round either the conversion factor or the quantity before performing the multiplication, as accuracy would be reduced. Use appropriate prefixes to eliminate insignificant, leading, or trailing zeroes.

9.5 Rounding—The rounding required by conversion and computation in SI units should be done using the following rules for the three general cases:

9.5.1 Where the digit immediately following the last digit to be retained is less than 5, the last digit retained should not be changed.

9.5.2 Where the digit immediately following the last digit to be retained is greater than 5 (or it is a 5 followed by at least one digit other than 0), the last digit should be increased by one.

9.5.3 Where the digit immediately following the last digit to be retained is exactly 5 (or it is a 5 followed by only zeroes), the last digit retained is not changed if it is even, and if it is odd it should be increased by one. For example, 4.365 00 becomes 4.36 when rounded to three digits. 4.355 00 also becomes 4.36 when rounded to three digits.

9.5.4 The above rules provide an additional observation about significant digits. The least significant digit (the last digit retained in the rounding process) cannot be considered more precise than 0.5 of its place value.
10. Accuracy of Conversion

10.1 It is important, in any conversion, to determine the accuracy of the original value and the repeatability of the converted value. Where interchangeability of converted values is required, IEEE/ASTM SI 10 should be consulted for exact procedures which will establish limits to the errors resulting from conversion calculations.

11. Special Ratios

11.1 Two special ratios\(^5\) are used in the maritime industry. These ratios are speed-length ratio, \(V/\sqrt{L}\), and displacement-length ratio, \(\Delta/(0.01 L)^3\)

where:
\(V = \) speed in knots,
\(L = \) length in feet, and
\(\Delta = \) displacement in long tons.

11.2 When using SI units, the speed-length ratio should be replaced by Froude number, \(v / (gL)^{0.5}\), in coherent units, where:
\(v = \) velocity,
\(g = \) gravitational acceleration, and
\(L = \) the ship’s length.

11.3 Similarly, the displacement-length ratio should be replaced by the volumetric coefficient, \(\pi / L^3\), in coherent units, where:
\(\pi = \) the underwater volume of the hull and
\(L = \) the ship’s length.

11.4 Speed-length ratio and displacement-length ratio are in common use because they have convenient values in their dimensional form. For example, \(V/\sqrt{L} = 1\) is significant from a wave resistance viewpoint. Using SI units would cause the numerical values of speed-length ratio to be multiplied by 1.81 and displacement-length ratio by 35.9.

11.5 Froude number is a factor of 0.298 times speed-length ratio. Since using SI units in dimensional speed-length ratio will change the values used, it is logical to use the dimensionless ratio, that is, the Froude number. Thus, Froude number should be used in place of speed-length ratio when designing in the SI system.

12. Conversion Factors

12.1 Table 6 and Table 7 provide conversion factors to SI for those quantities commonly used in the marine industry.

12.2 The maritime industry is subject to a complexity of national and international laws, treaties, regulations, and long term safety and contractual obligations which in some instances prevent unilateral changes from customary maritime language and usage of SI basic and supplementary terms. Therefore, Table 6 provides, in addition to the recommended SI units, a number of non-SI units permitted for use until such time as the preferred SI units can be adopted without detriment.

12.3 To convert a present unit to its equivalent SI unit or unit permitted for use, multiply the present unit in column 3 by the multiplication factor shown in column 6. To convert to present units, divide the SI unit by the factor.

12.4 Conversion factors are presented for ready adaptation to computer readout and electronic data transmission. The factors are written as a number equal to or greater than one and less than ten with six or fewer decimal places. This number is followed by the letter \(E\) (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example:

\[3.523 \times 10^{-2}\]

Similarly:

\[3.386 \times 10^{3}\]

</table>

A ISO number is from ISO 31 classification system.

B Units permitted for use with SI are in common use throughout the international maritime industry. The switch to preferred SI units should be made as conditions permit.

C Indicates exact conversion value.

D Minutes and seconds of plane angle may still be used for navigation purposes.

E For values of nautical mile and knot, see Table 6.

F Conversion based on the foot and one fathom equal to six feet.

G The volume measurement for those not using the metric system is generally 40 cubic feet, however, 50 cubic feet is used occasionally. It is recommended that the cubic metre (35.315 cubic feet) be used as the replacement unit. The conversion factor of one non-metric measurement ton (40 cubic feet) equals 1.132 67 cubic metres. One cubic metre of 35.315 cubic feet equals 0.883 non-metric measurement tons. The conversion of tariffs filed with the Federal Maritime Commission must be accomplished in accordance with their filing requirements.

H All tonnage measurements are long tons (2240 pounds). The short ton (2000 pounds) equals 0.907 185 t.

I An apparent anomaly exists in the case of the joule for work (J = N·m) and the use of N·m for torque or bending moment. These are, however, entirely different units. In the former, the unit of work results from unit force moving through unit distance. In the latter unit force acts at right angles to the lever arm of unit length. The distinction would be readily seen if vectors were incorporated in the unit symbols. For these reasons, it is important to express work or energy in joules and moment of force or torque in newton metres, not joules. The use of newton metre per radian as the unit of torque in rotational dynamics will result in dimensional integrity.

J It has been internationally recommended that pressure units themselves should not be modified to indicate whether pressure is “absolute” (that is above zero) or “gage” (that is, above atmospheric pressure). If, therefore, the context leaves any doubt as to which is meant, the word “pressure” must be qualified appropriately. (For example, “. . . at a gage pressure of 13 kPa” or “. . . at an absolute pressure of 13 kPa” or “. . . reached an absolute pressure of 13 kPa.”)

²Indicates exact conversion value.
³Unless otherwise noted, all tons are long tons (2240 lbs).
1. Scope

1.1 This specification provides design and construction criteria for double and single fire and foam station cabinets. See Fig. 1 and Fig. 2. Valves, hose, and fittings are not included.

1.2 Optional back and legs may be provided.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are for information only.

2. Referenced Documents

3. Classification

3.1 Type I, Single Cabinet (see Fig. 1 and Figs. 3-9):
3.1.1 Grade I—Right-hand door active leaf.
3.1.1.1 Class A, Mild Steel—Specification A 36/A 36M.
3.1.1.2 Class B, Stainless Steel—Specification A 167.
3.1.1.3 Class C, Aluminum—Specification B 209.
3.1.2 Grade 2—Left-hand door.
3.1.2.1 Class A, Mild Steel—Specification A 36/A 36M.
3.1.2.2 Class B, Stainless Steel—Specification A 167.
3.1.2.3 Class C, Aluminum—Specification B 209.

3.2 Type II, Double Cabinet (see Fig. 2 and Fig. 8):
3.2.1 Grade 1—Right-hand doors active leaf.
3.2.1.1 Class A, Mild Steel—Specification A 36/A 36M.
3.2.1.2 Class B, Stainless Steel—Specification A 167.
3.2.1.3 Class C, Aluminum—Specification B 209.

4. Ordering Information
4.1 Fire and foam cabinets ordered in accordance with this specification shall include the following:
4.1.1 ASTM title, designation, and year of issue,
4.1.2 Quantity (number of cabinets),
4.1.3 Type, grade, and class, and
4.1.4 Optional features.

5. Materials and Manufacture
5.1 Materials:
5.1.1 See Table 1.
5.1.2 Class materials.
5.1.2.1 All materials for Class A cabinets shall meet the requirements of Specifications A 53 and A 36/A 36M or Specification A 569/A 569M, except as specified in Table 1.
5.1.2.2 All materials for Class B cabinets shall meet the requirements of Specifications A 167 and A 312/A 312M, except as specified in Table 1.
5.1.2.3 All materials for Class C cabinets shall meet the requirements of Specifications B 209 and B 221 except as specified in Table 1.

5.2 Manufacture:
5.2.1 Welding shall be in accordance with the American Bureau of Shipping Rules for Building and Classing of Vessels or American Welding Society Structural Welding Code AWS D1.1.
5.2.2 Punchout shall have a 3-in. (approximately 76-mm) diameter hole with three evenly spaced 1⁄16-in. (approximately 1.5-mm) tabs for both sides of cabinet (see Fig. 3).

6. Workmanship, Finish, and Appearance
6.1 Fire and foam cabinets shall be free of weld spatter, burrs, and sharp corners, rough edges, and other defects which might be hazardous to personnel and equipment.
6.2 Surface Requirements:
6.2.1 Class A Cabinets—Coat with 1.0-mil dry film thickness, inorganic zinc silicate, including options.
6.2.2 Class B Cabinets—Uncoated. Optional legs coated with 1.0-mil dry film thickness, inorganic zinc silicate.
6.2.3 Class C Cabinets—Uncoated.

7. Packaging and Package Marking
7.1 Loose fasteners and hardware shall be packaged and securely attached inside each cabinet.
7.2 Shipping—Each cabinet shall bear a weathertight tag showing the purchase order number, ASTM standard designation, type, and name of manufacturer.
7.3 The cabinets shall be crated or attached to a pallet in a manner acceptable for shipment by commercial carrier. The cabinets shall be crated individually.

Standard Practice for
Human Engineering Program Requirements for Ships and
Marine Systems, Equipment, and Facilities

This standard is issued under the fixed designation F 1337; the number immediately following the designation indicates the year of
original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A
superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice establishes and defines the requirements for
applying human engineering to the development and
acquisition of ships and marine systems, equipment, and
facilities. These requirements are applicable to all phases of
development, acquisition, and testing and shall be integrated
with the total system engineering and development, and test
effort. It is not expected nor intended that all of the human
engineering activities should be applied to every marine
program or program phase. Therefore, these activities shall be
tailored to meet the specific needs of each program and the
milestone phase of the program within the overall life cycle.
This tailoring shall be performed by the procuring activity or
by the contractor or subcontractor with the assistance and
approval of the procuring activity in order to impose only the
essential human engineering requirements on each program.
Guidance for selection of only the essential requirements is
contained in Appendix X1.

SNAME Sample Model Specification for Human Engineer-
ing Purposes—Technical and Research Bulletin 4–22

3. Terminology

3.1 Definitions of Terms Specific to This Standard:
3.1.1 arrangement drawings—engineering design drawings
that provide plan, sectional, and elevation views of: (1) the
configuration and arrangement of major items of equipment
for manned compartments, spaces, or individual work stations, and
(2) within the work station, such as in a modular rack or on a
fiddleboard.

3.1.2 critical activity—any human activity that if not ac-

3.1.3 cultural expectation—the cause and effect relation-
ships (for example, red means stop or danger) that humans
learn from their culture.

3.1.4 duty—a set of operationally related tasks within a
given job (for example, communicating, operator mainte-
nance).

3.1.5 function—an activity performed by a system (for
example, provide electric power) to meet mission objectives.

3.1.6 human engineering—a specialized engineering disci-
pline within the area of human factors that applies scientific
knowledge of human physiological and psychological capabili-
ties and limitations to the design of hardware to achieve
effective man-machine integration.

3.1.7 human factors—the application of scientific knowl-
edge about human characteristics, covering both biomedical
and psychosocial considerations, to complete systems, indi-
vidual equipments, software, and facilities. This application is
through such specialized fields as human engineering, man-
ning, personnel selection, training, training devices and simu-
lation, life support, safety, job performance aids, and human
performance testing and evaluation.

3.1.8 human interface—any direct contact (that is, physical,
visual, or auditory) with a piece of hardware or software by a
human operator or maintainer.

3.1.9 job—the combination of all human performance re-
quired for operation and maintenance of one personnel position
in a system.

3.1.10 life support—that area of human factors that applies
scientific knowledge regarding the effects of environmental
factors on human behavior and performance to items that
require special attention or provisions for health promotion,
biomedical aspects of safety, protection, sustenance, escape,
survival, and recovery of personnel.

3.1.11 mission—a specific performance requirement im-
posed on one or more systems (for example, unload cargo)
within the operational requirements.

1 This practice is under the jurisdiction of ASTM Committee F25 on Ships and
Marine Technology and is the direct responsibility of Subcommittee F25.07 on
General Requirements.

3 Available from Society of Naval Architects and Marine Engineers, 601 Pavonia
Ave., Jersey City, NJ 07306, Attn: Technical Coordinator.
3.1.12 operational requirements—requirements under which the platform, system, equipment, or software will be expected to operate and be maintained (for example, day/night, all weather operation, sea state, speed, endurance) while completing a specific mission or missions.

3.1.13 panel layout drawings—detailed drawings that include such features as: a scale layout of the controls and displays on each panel or an item of equipment such as a shipboard command console; a description of all symbols used; identification of the color coding used for displays and controls; the labeling used on each control or display; and the identification of control type (for example, alternate action or momentary), also screen layouts for software generated displays.

3.1.14 platform—the major hardware (for example, ship, off-shore rig, barge, submarine) on, or in which, the individual equipment, system, or software will be installed or added.

3.1.15 spatial relationships—placement of multiple but separate components of a system together, so it is visually obvious that the components are related and used together, or placement of identical components used on multiple systems to provide the user with a spatial clue as to where the components are located.

3.1.16 subtask—activities (perceptions, decisions, and responses) that fulfill a portion of the immediate purpose within a task (for example, remove washers and nuts on the water pump).

3.1.17 system—a composite of subsystems, including equipment, communications, software, and personnel that either independently, or in conjunction with other systems, performs functions.

3.1.18 system analysis—a basic tool for systematically defining the roles of and interactions between the equipment, personnel, communications, and software of one or more systems. It is an iterative process, requiring updating. Used in the early phases of design, it can be useful in allocating assignment of tasks to personnel, equipment, software, or some combination thereof. Done in later design stages, it can serve as the basis for the arrangement of equipment and work stations.

3.1.19 task—a composite of related activities (perceptions, decisions, and responses) performed for an immediate purpose, written in operator/maintainer language (for example, change a water pump).

3.1.20 task analysis—a method used to develop a time-oriented description of the interactions between the human operator/maintainer and the equipment or software in accomplishing a unit of work with a system or individual piece of equipment. It shows the sequential and simultaneous manual and intellectual activities of personnel operating, maintaining, or controlling equipment, in addition to sequential operation of the equipment.

3.1.21 task element—the smallest logically and reasonably definable unit of behavior required in completing a task or subtask (for example, apply counterclockwise torque to the nuts, on the water pump, with a wrench).

3.1.22 vendor drawings—design drawings prepared by the manufacturer of an individual piece of equipment which is purchased for installation aboard a ship or other marine platform.

4. Summary of Practice

4.1 Human Engineering Program Plan—The human engineering program plan, in accordance with the requirements of this practice and the equipment or ship specification, shall include the tasks to be performed, human engineering milestones, level of effort, methods to be used, design concepts to be used, and the test and evaluation program, in terms of an integrated effort within the total project.

4.2 Quality Assurance—Verification of compliance with the requirements of this practice and other human engineering requirements specified by the contract will be the responsibility of the procuring activity. Human engineering performed during the development program by a contractor or subcontractor shall be demonstrated to the satisfaction of the procuring activity at the scheduled design and configuration reviews and inspections, as well as during development test and evaluation inspections, demonstrations, and tests.

4.3 Nonduplication—The efforts performed to fulfill the human engineering requirements specified herein shall be coordinated with, but not duplicate, efforts performed in accordance with other requirements. Necessary extensions or transformations of the results of other efforts for use in the human engineering program will not be considered duplication. Instances of duplication or conflict shall be brought to the attention of the procuring activity.

4.4 Cognizance and Coordination—The human engineering program shall be coordinated with maintainability, system safety, reliability, survivability/vulnerability, and integrated logistic support, as well as other human factors functions, such as life support and safety, personnel selection, preparation of job aids, and training. Results of human engineering analysis or lessons learned information shall be incorporated into the logistic support analysis as applicable. The human engineering portion of any analysis, design and development, or test and evaluation program shall be conducted by, or under the direct cognizance of, personnel properly trained and experienced in human engineering and assigned the human engineering responsibility by the contractor or subcontractor.

5. Significance and Use

5.1 Intended Use—Compliance with this practice will provide the procuring activity with assurance that the operator/maintainer will be efficient and effective in the operation and maintenance of systems, equipment and facilities. Specifically, it is intended to ensure that:

5.1.1 System performance requirements are achieved by appropriate use of the human component.

5.1.2 Proper design of equipment, software and environment permits the personnel-equipment/software combination to meet system performance goals.

5.1.3 Design features will not constitute a hazard to personnel.
5.1.4 Trade-offs between automated versus manual operation have been chosen for peak system efficiency within appropriate cost limits.

5.1.5 Application of selected human engineering design standards are technically adequate and appropriate.

5.1.6 Systems and equipments are designed to facilitate required maintenance.

5.1.7 Procedures for operating and maintaining equipment are efficient, reliable and safe.

5.1.8 Potential error-inducing equipment design features are eliminated, or at least, minimized.

5.1.9 Layouts and arrangements of equipment afford efficient communication and use, and

5.1.10 Contractors provide the necessary, technically qualified manpower to accomplish the objectives listed.

5.2 Scope and Nature of Work—The human engineering effort shall include, but not necessarily be limited to, active participation in three major interrelated areas of platform, system, and equipment development.

5.2.1 Analysis—Starting with a mission analysis developed within baseline operational requirements, the functions that must be performed by the system in achieving its mission objectives shall be identified and described. These functions shall be analyzed to determine the best allocation to personnel, equipment, software, or combinations thereof. Allocated functions shall be further dissected to define the specific tasks that must be performed to accomplish the functions. Each task shall be analyzed to determine the human performance parameters, the system/equipment/software capabilities, and the operational/environmental conditions under which the tasks are conducted. Task performance parameters shall be quantified, where possible, and in a form permitting effectiveness studies of the crew-equipment/software interfaces in relation to the total system operation. Human engineering high risk areas shall be identified as part of the analysis.

5.2.2 Design and Development—Design and development of the equipment, software, systems, and total platforms requiring personnel as operators or maintainers, or both, shall include a human engineering effort that will ensure that adequate and appropriate human engineering design standards are incorporated into the overall engineering design. Such standards may be specifically stated in the system equipment, software, or facilities acquisition specifications, or they may be generated from the analysis work completed prior to design and development.

5.2.3 Test and Evaluation—Test and evaluation shall be conducted with the newly designed equipment, software, facilities, and environment to verify that they meet human engineering and life support criteria and are compatible with the overall system requirements. This shall include periodic on-site checks of the platform, systems, equipment, software, or facilities during construction to ensure that changes are not made during construction that would degrade earlier human engineering efforts.

6. Human Engineering Activities

6.1 Scope—The human engineering program shall include the following activities:

6.1.1 Operational Requirements (OR)—Operational requirements (ORs) are established first to define the parameters within which the individual equipment, system, or total platform shall be expected to perform. ORs shall be expressed in such terms as the weather conditions under which it must operate (for example, rain, snow, sea state limits); number of days it must operate without being refueled or resupplied; and maximum number of personnel that will be available to operate and maintain the hardware. Human engineering shall be considered in the development of ORs, especially when the ORs include requirements on the number, type, or training of operators or maintainers, or both.

6.1.2 Mission Requirements Analysis—Mission requirements define the performance parameters of the equipment, system, or total platform in greater detail than that provided by the ORs, and in terms of specific activities the hardware/software is supposed to accomplish. Human engineering shall be involved in establishing the mission requirements since the human’s capabilities or limitations may well be a controlling factor regarding whether or not the mission requirements can be met.

6.1.3 System Requirements Analysis—System requirements analyses define the specific systems that will be needed to successfully complete each of the missions delineated above. Human engineering shall be involved in establishing system requirements, since some systems can require greater numbers of personnel and higher skill levels for operators or maintainers than others. Human engineering data from existing systems similar to those being proposed for the new design may be used as a baseline in defining the new system requirements.

6.1.4 Function Definition—The functions that must be performed by each system to achieve the desired mission objectives shall be defined. This definition shall be done without consideration as to whether the function will be performed by a human, by a machine, or by a combination of the two. Functions shall be stated as a required action (for example, monitor, receive, communicate, view, send, calibrate). Functional block diagrams shall be used, as appropriate, as a presentation tool. Functional definitions shall be as detailed as is necessary to permit the successful allocation of the functions. The transfer and processing of information (for example, verbal communications, electronic transmissions, printed material) shall be identified as a function but without reference to specific machine or human involvement. Human engineers shall be involved in identifying functions, since this activity serves as the base for the next step, which includes major participation by human engineering.

6.1.5 Function Allocation—Each function identified from the previous step shall be assigned to be machine implemented, performed by software, reserved for the human operator/maintainer, or performed by some combination thereof. Human engineering specialists shall participate in the function allocation process to ensure that each function assigned to the human is within the human’s capability. Known human engineering experiences with man-machine functional allocations on existing equipments, systems, or platforms similar to those under evaluation; personal human engineering experience in the function allocation field; and available information on human
physical and psychological performance capabilities shall be used when applicable in determining function allocations.

6.1.6 Equipment Selection—Hardware and software shall be selected to perform those functions assigned to them from the function allocation activity. Human engineering principles and design standards shall be included, along with other design considerations, in identifying and selecting that hardware/software. Human engineers shall ensure that the equipment provides the human with the opportunity to complete those functions assigned to the operator/maintainer, and that it complies with all of the applicable design criteria contained in Practice F 1166, as well as other human engineering design criteria contained in the contract, or in other human engineering design standards referenced in the contract. Known human engineering problems with equipment now in service (for example, information from equipment casualty reports or personnel injury data associated with equipment failure) is similar to that being considered, personal experience with applying human engineering design criteria to equipment design, and review of potential supplier engineering data are examples of the human engineering resources that shall be used in assessing the acceptance of the selected equipment from a human engineering viewpoint.

6.1.7 Human Engineering System Analysis Report (HESAR):

6.1.7.1 HESAR (TYPE 1)—Type 1 HESARs, which are prepared early in the design process (for example, during feasibility design), shall allow for the evaluation of the appropriateness and feasibility, from a human engineering perspective, of the mission, system, and functional requirements, and to serve as one basis for decisions made during the functional allocation effort. The HESAR shall contain the results of the mission, system, and functional requirements analyses and describe the human engineering rationale for, or contribution to, each. In addition, the potential impact, or the proposed use, of these analyses for future human engineering activities (for example, allocation of functions, equipment selection, detail design of equipment, arrangement of spaces or compartments) shall be discussed. The objective of the early HESAR shall be to demonstrate that human engineering considerations have been adequately addressed in the establishment of the mission, system, and functional requirements, and that there exists a sound basis on which to allocate the functions, select the equipment, and perform the detail design of the individual piece of equipment, system, or total platform.

6.1.7.2 HESAR (TYPE 2)—A Type 2 system analysis, completed late in the design process (for example, during development of construction drawings or production drawings) shall be done to provide a basis on which to base a particular equipment design, or system or compartment arrangement. In completing a Type 2 system analysis the following factors shall be considered, and shall be discussed in the HESAR: (1) description of the equipment, console, compartment, system, or work station on which the analysis was conducted, (2) externally imposed design requirements or criteria over which the human engineer had no control (for example, number of operators/maintainers, specific types and numbers of consoles, previously determined man-machine function allocations, predetermined locations of hardware), (3) communications requirements (for example, telephone, voice, sound powered phones, electronic), (4) work environment, (5) mission, system, backup, and functional requirements, and (6) human physical and psychological capabilities within the context of the existing design parameters. In conducting the analysis, consideration shall be given to such issues as projected work loads for each manned position; the kind, amount, and criticality of the information that goes into, and out of, each operator/maintainer station; the need for direct voice or visual communication between manned positions; location and suitability of backup equipment in case the primary hardware fails; and the interactions that are required between personnel or equipment, or both. Using the completed analysis, the human engineer shall participate in establishing the final design or arrangement of a piece of equipment, a system, or the total platform.

6.1.8 Task Analysis:

6.1.8.1 Concurrence and Availability—All task analyses shall be modified as required to remain current with the design effort and shall be available to the procuring activity as requested.

6.1.8.2 Gross Task Analysis (GTA)—A GTA consists of defining the major tasks required of the human operator/maintainer to complete each function identified and allocated to the human during the functional allocation activity (see 6.1.5). The GTA shall present these tasks in the sequence in which they must be completed and against an established time line reference. Information flows into, or out from, the human shall be included as a task. The GTA shall include both manual and cognitive tasks, and shall be written in operator/maintainer language (for example, change fuel pump, steer ship on constant heading, calculate fuel consumption rate). Where GTAs are required they shall be performed for both normal and emergency operating conditions. The GTAs shall be used to determine, to the extent practicable, whether the system performance requirements (see 6.1.3) can be met with the function allocations, backup facilities, and equipment selections that have been previously made. These analyses shall also be used as basic information for developing preliminary manning levels; equipment procedures; personnel skill, training, and communication requirements; and as logistic support analysis inputs. Personal experience of the human engineering analyst in the preparation of GTAs, information from equipment vendor operation and maintenance manuals, inputs from the design engineers (either at the procuring activity or the contractor) of the system(s) or equipment under evaluation, and established tasks on equipment similar to that under investigation are all resources that shall be used as appropriate in the creation of GTAs. GTAs shall be presented in diagrammatic form (for example, operational sequence diagrams) unless otherwise approved by the procuring activity.

6.1.8.3 Critical Task Analysis (CTA)—Those gross tasks identified in the GTA that require critical human performance (for example, no deviation from a fixed sequence; task completion within a fixed, and limited, time frame; accurate setting or reading of an important control or display), reflect possible unsafe practices, or that are subject to promising improvements
in operating efficiency shall be identified and further analyzed upon approval of the procuring activity. CTAs require detail to the subtask (for example, remove hose clamp from hose on the discharge side of water pump), or even task element level (for example, turn screw on the hose clamp on discharge side of water pump counterclockwise with Phillips head screwdriver). Other inputs which shall be made to a CTA include: (1) information required by the operator/maintainer for task initiation, (2) all information available to the operator/maintainer, (3) cognitive functions required of the operator/maintainer to process or act on the information, (4) actions required by the human based on the cognitive processes, (5) workspace envelope required by the actions, (6) workspace available, (7) frequency and accuracy required of the actions, (8) feedback required to the operator/maintainer regarding the adequacy of his/her actions, (9) tools or equipment, or both, required by the human, (10) job aids or references required, (11) number of personnel required or provided, as well as their specialty and experience, (12) communications required, and the types of communications, (13) safety hazards involved, (14) operational requirements of the human (for example, hours on duty, number of repetitive motions), (15) backup facilities available, and (16) operator interaction where more than one person is involved. The format shall include a time line base for presenting the information listed herein. Task analysis may be produced by automated programs after review and approval of the programs by the procuring activity.

6.1.9 Human Engineering Design—Human engineering principles and design standards shall be applied to the design of all compartments, spaces, systems, individual equipment, work stations, and facilities in which there is a human interface. Drawings, specifications, analyses, or other documentation shall reflect incorporation of these human engineering principles and standards. Where specific design criteria are required, they shall conform to Practice F 1166 or other human engineering criteria required by the contract. Design of the compartments, spaces, equipment, systems, work stations, and facilities shall provide for both normal and emergency conditions, and shall consider at least the following where applicable:

6.1.9.1 Environmental conditions, such as temperature, humidity, air flow, noise and illumination levels, and atmospheric contaminants,

6.1.9.2 Weather and climate, such as rain, snow, and ice,

6.1.9.3 Platform motion (for example, ship roll and pitch),

6.1.9.4 Space (that is, access) requirements for personnel to perform operations and maintenance, keeping in mind the special clothing or protective gear they may be wearing and the tools they may be carrying,

6.1.9.5 Safe and efficient walkways, ladders, work platforms, and inclines,

6.1.9.6 Adequate physical, visual, and auditory links between personnel, and between personnel and their equipment so that reach and visual envelopes are within standard limitations,

6.1.9.7 Provisions to minimize physical or emotional fatigue,

6.1.9.8 The effects on physiological and psychological performance due to special clothing, or chemical, biological, and radiological (CBR) protective suits,

6.1.9.9 Provisions to maximize cultural expectations and spatial relationships in the design,

6.1.9.10 Equipment removal and stores handling provisions,

6.1.9.11 Crew safety requirements, and

6.1.9.12 The range in physical size (for example, 5th to 95th percentile dimensions) and mental capabilities of the anticipated users of the equipment.

6.1.9.13 The adequacy of including human engineering principles and design standards into the overall design effort shall be evaluated during design reviews. Where such reviews involve a contractor or subcontractor, the individuals assigned the human engineering responsibilities by these organizations shall participate in the reviews. At quarterly design reviews these individuals shall provide the same type of presentation as is made by the other engineering disciplines.

6.1.10 Application of Lessons Learned Information—Information on known or suspected human engineering problems from past or existing equipments, systems, or total platforms similar to that under design shall be obtained and used in the design of the new equipment, system, or platform. This information shall be acquired from such sources as: personal inspection of current hardware, system, or platform (for example, conduct a ship check or ship survey), interviews with past or current operators or maintainers, or both, a review of sea trial deficiency cards, discussions with past or current designers of similar equipments, systems, or platforms, and investigation of personnel injury or equipment casualty reports, or both. Any summation reports prepared from the acquisition of this data shall provide the information by equipment, system, or ship compartment and shall include the ship work breakdown structure (SWBS) number or other corresponding specification section for each identified human engineering problem.

6.1.11 Engineering Design Drawings—Human engineering principles and design standards shall be reflected in the engineering design drawings produced for marine systems and equipment. These principles and standards shall be incorporated in all engineering drawings that involve a human interface and are developed during the various design phases. Specific types of drawings to which the human engineering principles and design standards shall be applied include: overall platform (for example, ship, off-shore rig, barge) arrangement drawings, individual compartment or space arrangement drawings, zone arrangement drawings, console or work station panel layout drawings, individual equipment design drawings, piping arrangement drawings, and other drawings depicting the design or arrangement, or both, of equipment requiring operation or maintenance, or both, by humans. The drawings shall comply with the applicable criteria contained in Practice F 1166 or other human engineering design standards, or a combination thereof, as specified in the contract.

6.1.11.1 Where the drawings are produced by a contractor, a specific list of the engineering drawings or a description of the types of drawings that will receive human engineering input
shall be included in the contractor’s human engineering program plan (HEPP). Personnel assigned human engineering responsibility by the contractor shall approve all drawings included in the HEPP list before the drawings are released for production.

6.1.12 Human Engineering in Vendor Hardware/Software—Human engineering principles and design criteria from Practice F 1166 (or other approved design standards) shall be incorporated into hardware and software purchased by the contractor for inclusion on a marine platform or major system. The human engineering program plan shall include a list of the hardware/software items on which human engineering principles and design criteria will be imposed. The contractor shall also ensure that the vendor hardware/software complies with the design standards of Practice F 1166 after installation in or on the platform or system.

6.1.13 Studies, Experiments, and Laboratory Tests—The contractor shall conduct experiments, tests (including dynamic simulation per 6.1.14), and studies required to resolve human engineering and life support problems specific to the system. Human engineering and life support problem areas shall be brought to the attention of the procuring activity, and shall include the estimated effect on the system if the problem is not studied and resolved. These experiments, tests, and studies shall be accomplished in a timely manner, that is, such that the results may be incorporated into the design. The performance of any major study effort shall require approval by the procuring activity.

6.1.14 Dynamic Simulation Studies—Dynamic simulation studies shall be used as a human engineering design tool when necessary for the detail design of equipment requiring critical human activity (for example, precise ship maneuvering or handling tasks). If such studies are completed, the simulation hardware/software should be evaluated as a training tool as well, and shall be addressed in the dynamic simulation plan. No dynamic simulation studies shall be performed without prior approval of the simulation plan by the procuring activity.

6.1.15 Mockups and Models—Models and mockups built to resolve access, workspace design, equipment arrangements, or other human engineering problems shall be constructed at the earliest practical point and well before fabrication of the compartment, system, or equipment. The proposed human engineering program plan shall specify which models and mockups the contractor proposes to use for human engineering purposes. Mockups shall be full scale and models shall be built to SNAME Sample Model Specification for Human Engineering Purposes—Technical and Research Bulletin 4-22. For models and mockups specified primarily for human engineering use, the workmanship shall be no more elaborate than is necessary to determine the adequacy of size, shape, arrangement, access, or panel content of the equipment for human use. Models and mockups shall be constructed as simply and inexpensively as is compatible with the objective and use. They shall be updated regularly to reflect the latest designs. Upon approval by the procuring activity, scale models may be substituted for mockups. The models and mockups shall be available for inspection as determined by the procuring activity. Mockups and models may be disposed of only with the approval of the procuring activity.

6.1.16 Human Engineering in Performance and Design Specifications—Where the contractor prepares a specification for the design, development, construction, or acquisition of a marine platform, system, piece of equipment, facility or software, it shall conform to applicable human engineering criteria of Practice F 1166 and other human engineering criteria specified by the procuring agency.

6.1.17 Equipment Procedure Plates and Manuals—The contractor shall apply human engineering principles and criteria to the development of procedures and manuals for operating, maintaining, or otherwise using the system and equipment. For individual procedure plates (for example, lubrication charts, hazard warnings, operating instructions, schematics), mounted at the equipment, they shall comply with the design requirements in Practice F 1166. For computer systems, human engineering shall be applied throughout software program planning and development. This effort shall be accomplished to ensure that the procedures are concise, unambiguous, and easy to read and follow with a consistent presentation format, especially for the hazard identification statements. The results of this effort shall be reflected in the preparation of user-oriented operational, training, and technical plates, manuals, and other publications.

6.1.18 Human Engineering Design Approach Document (HEDAD)—Two types of HEDADs shall be prepared: the HEDAD-operator (HEDAD-O) and the HEDAD-maintainer (HEDAD-M).

6.1.18.1 HEDAD-O—The HEDAD-O shall describe the as-built system or equipment (for example, console, specific work station, compartment arrangement, lube oil system) from an operator’s perspective. The system or equipment shall be described in detail (for example, each display or control on a console; each pump, controller, and meter in the lube oil system) explaining the design, layout, and location of each component from a human engineering perspective. The HEDAD-O shall describe where each component is located, why it was designed the way it appears in the finished product, and why the as-built arrangement was selected (that is, the human engineering rationale). The HEDAD-O shall provide the procuring activity with sufficient detail to evaluate the as-built system or equipment to ensure that it is operable and complies with the human engineering requirements contained in the system or equipment design and acquisition contract.

6.1.18.2 HEDAD-M—The HEDAD-M shall be prepared in the same manner and detail as the HEDAD-O but shall describe the system or equipment from a maintenance perspective. In addition to a description of each component, such items as access openings, test or calibration points, lubrication fittings, and other maintenance specific design features shall be identified and discussed. The HEDAD-M shall be in sufficient detail to allow the procuring activity to determine that the system or equipment is maintainable and complies with the human engineering requirements contained in the design and acquisition contract.
6.1.18.3 General Requirements—The systems or equipment that will receive a HEDAD during design and development shall be listed in the contractor’s human engineering program plan along with a brief rationale as to why the particular HEDADs were selected (the explanation is required only if the contractor was allowed to select the HEDADs). A brief discussion of the contractor’s proposed methodology for completing the HEDADs shall also be included in his plan. The contractor shall include drawings (for example, console panel layouts; system arrangement; plan, section, and elevations for work stations), photos, or other visual aids as necessary to assist in describing the system or equipment.

6.1.19 Human Engineering Progress Report (HEPR)—HEPRs shall be prepared by the contractor and submitted on a regular basis to the procuring activity. The reports shall be concise, but in sufficient detail to allow the procuring activity to assess the adequacy of the contractor’s human engineering program. Information on work accomplished, human engineering problems encountered and solutions generated, as well as projected activity for the next reporting period shall be included.

7. Test and Evaluation

7.1 Human Engineering in Test and Evaluation—The contractor shall establish and conduct a test and evaluation program to:

7.1.1 Demonstrate conformance of marine system, equipment and facility design to human engineering design criteria.
7.1.2 Confirm compliance with overall system performance requirements where personnel could be a performance determinant.
7.1.3 Secure quantitative measures of system performance which are a function of the human interaction with equipment, and
7.1.4 Determine whether undesirable design or procedural features have been introduced, but went undetected, during design and development. The test and evaluation effort may be required at various stages in system, subsystem, or equipment development but these shall not preclude final human engineering verification of the complete system. The human engineering test and evaluation program shall include both operator and maintenance tasks as described in a test plan approved by the procuring activity.

7.2 Planning—Human engineering testing shall be incorporated into the total platform, or individual system, hardware, or software test and evaluation program. The test requirements shall be satisfied through integration with the equipment engineering acceptance tests, contractor demonstrations, ship trials, research and development acceptance tests, or dedicated human engineering tests using actual hardware or mockups. Compliance with human engineering requirements shall be tested as early as possible. Human engineering findings from design reviews, mockup inspections, demonstrations, and other early engineering tests shall be used in planning and conducting later tests.

7.3 Human Engineering Test Plan—A human engineering test plan (HETP) shall be prepared describing when, how, and who will complete the human engineering test and evaluation program. For smaller or less complex systems, the HETP may be submitted as part of the HEPP. If the plan is prepared by a contractor, it shall be approved by the procuring activity before the start of testing. The plan shall describe the proposed test and evaluation program in sufficient detail to permit the procuring activity to determine if the test program will meet the objectives listed in 7.1. The plan shall be prepared so that the human engineering tests will involve individuals representative of the intended user population, performing actual (or simulated) operational and maintenance tasks, under actual or realistic operating environments, and using garments and equipment appropriate to the tasks involved in the tests. The plan shall require that all failures occurring during test and evaluation shall be subjected to a human engineering review to differentiate between failures caused by equipment alone, personnel-equipment incompatibilities and those caused by personnel alone. The contractor shall identify and notify the procuring activity of suspected design conditions which contributed substantially to or induced human error and shall propose appropriate solutions to these conditions.

7.4 Human Engineering Test Reports (HETR)—An HETR shall be prepared for each human engineering test conducted. It shall describe the equipment tested, the test conditions, test subjects, test procedures, results, and design recommendations coming from the test results. For small or less complex systems, the HETR may be submitted as part of the HEPR.

8. Documentation

8.1 Data Requirements—Human engineering data requirements shall be as specified by the contract. See Appendix X2.

8.1.1 Traceability—The contractor shall document his human engineering efforts to provide traceability from the initial identification of human engineering requirements during analysis or system engineering, or both, through design and development to the verification of these requirements during test and evaluation of approved design, software, and procedures. Each human engineering input made during design, construction, and test shall be recorded to indicate that the input was included in the finished product or rationale for exclusion.

8.1.2 Access—All data, such as plans, analyses, design review results, drawings, checklists, design and test notes, and other supporting background documents reflecting human engineering actions and decision rationale, shall be maintained and made available at the contractor’s facilities to the procuring activity for meetings, reviews, audits, demonstrations, test and evaluation, and related functions.

9. Keywords

9.1 drawings; equipment; human engineering; human engineering program; human factors; program; ships; system
X1.1 Scope

X1.1.1 It is not expected nor desired that every human engineering activity contained in this practice should be completed on every marine contract. Therefore, this practice is deliberately constructed to allow the procuring activity, (or the contractor, if directed to do so), to choose only those activities that will directly benefit each contract. This appendix provides guidance and selection criteria to assist in picking from all the human engineering activities described in this practice only those that are necessary for each contract.

X1.2 Tailoring

X1.2.1 General

The underlying purpose for any human engineering program on an equipment, system, or platform design and development contract is to influence the design of the hardware/software, not to produce paper. Lengthy studies, unnecessary analyses, wordy progress reports, simulation studies that make no direct contribution to design, unproductive human engineering test programs, and system analysis studies done after design is frozen are wasteful and undesirable. Thus, every human engineering activity included in a contract must be directly oriented to maximizing the human’s contribution to the overall successful operation of the hardware/software under design. That is why decisions to include human engineering and which activities, must be done by human engineering specialists, either at the procuring activity, or within the contractor’s organization.

X1.2.2 Selection Guide:

X1.2.2.1 General

The decision as to whether or not to invoke this practice as a mandatory provision on design and development contracts for marine equipments, systems, or platforms is dependent on several factors including: (1) the type of hardware/software (in terms of operation and maintenance requirements), (2) the degree to which the human is involved in the operation or maintenance of the hardware/software, and (3) the point in the design process when human engineering becomes involved. Use of any, or all, of the requirements in this practice should not normally depend on hardware size (that is, big ship versus little ship), system complexity, hardware duty cycles, number of human operators/maintainers involved, or, within practical limits, the contract type, cost, duration, or size of production lots. These factors may influence the kind, or number, of human engineering activities selected for the contract, but not the decision to include or exclude a human engineering program in the contract.

X1.2.2.2 Specification Requirement

For most contracts, but particularly fixed price contracts, the specification, circular of requirements (COR), or statement of work (SOW) shall clearly define which of the human engineering activities from this practice shall be performed by the contractor. The responsibility for selecting these activities must rest with the human engineering specialists within the procuring activity. For cost plus contracts, the contractor is sometimes given the responsibility to define the human engineering program, with procuring activity approval. Therefore, this tailoring guide should be used by whomever shapes the human engineering program.

X1.2.2.3 Selection Guidelines (General)

Generally, human engineering activities from this practice should not be included in a contract that covers parts, subassemblies, or other small components (for example, bearings, transformers, wheels). Likewise, the practice should normally not be considered for use in hardware/software development contracts where human involvement or interface is obviously insignificant. In contrast, if the request for proposals (RFP) specification, or other contract documentation states performance requirements or goals (for example, accuracy, time limits, maximum error rates, mean time to repair) to which the human operator/maintainer can reasonably be considered to contribute, then this practice should be used.

X1.2.2.4 Phases of the Acquisition Process

There are distinct phases in the acquisition of a new platform (ship), system, or equipment. For a system or equipment these are normally concept exploration, demonstration and validation, full-scale development, and production and deployment. For a ship these four phases are feasibility studies, preliminary design, contract design, and detail design and construction.

X1.2.2.5 Selection Guidelines (Particular)

A more specific guideline for selecting particular activities from the practice is included in Table X1.1. The table shows the human engineering activities and requirements, identified by paragraph number and title. It also shows the four stages of the design process commonly found in the marine design and development world. For each intersection of design phase and human engineering activity, a letter indicates whether the activity is normally required (R), possibly completed (P), or normally not completed (N) for that design phase. A (—) implies that the activity discussed in the practice is given for informational purposes only and not as a contract requirement. Table X1.1, therefore, provides some guidance as to where along the design and development process each of the human engineering activities should be applied.

X1.2.2.6 Evolutionary Design and Development

The use of Table X1.1 is directed at the design and development of new equipments, systems, or platforms. However, much of the design effort in the marine world is devoted to improving one particular piece of equipment, or upgrading one, or a few, compartments on a platform (for example, overhaul of a ship engine room or conversion of a propulsion plant). It is also common to take an existing system (for example, lube oil, water purification, sanitary treatment) or platform (that is, ship) and design and build a new one while...
using much of the old one as a baseline design. Under these circumstances it is normal procedure to apply the human engineering activities listed in the practice to only those equipments, systems, or platform alterations which are being changed from the baseline. As for the specific activities to be included, those listed for detail design and construction are the most likely to be appropriate.

X1.2.2.7 Summary

Although the general and particular guidelines provided above can be helpful in tailoring the human engineering requirements contained in this practice to a specific design and development contract, they are not foolproof. That is why it is so important to have the tailoring done by a human engineering specialist with experience in the marine design and construction business. No tailoring guide can be as effective in defining a good human engineering program as the academic and experiential background possessed by a human engineering specialist in the marine world.

X2. DATA REQUIREMENTS

X2.1 Government Data Requirements—For government procurements, in which the use of a Contract Data Requirements List (DD 1423) is a requirement, the Data Item Descriptions (DID) should be used when applicable.

X2.2 Commercial Data Requirements—For commercial procurements, the data requirements should be included in the contract in the manner commonly used for other data requirements.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Guide for
Main Propulsion Medium Speed Marine Diesel Engines
Covering Performance and Minimum Scope of Assembly

This standard is issued under the fixed designation F 1338; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers performance and minimum scope of assembly of all medium speed marine diesel engines intended for main propulsion of single or multiple screw propelled marine vessels or for vessels using other than screw propeller-type main propulsion.

1.2 This guide is intended to supplement the regulations of legally constituted regulating authorities. In the event of any conflict, which may become apparent after publication of this guide, with such legally constituted regulations, the latter shall take precedence, as may be applicable within the jurisdiction of such authorities and specific to each case, unless such latter regulations are formally waived by proper cognizant authority.

1.3 This guide is not intended to relieve the purchaser of the obligation fully to advise the engine builder of all of the purchaser’s unique operational considerations to allow those considerations to be satisfied.

2. Referenced Documents

2.1 ABS Standard: Rules for Building and Classing Steel Vessels
2.2 IEEE Standard: Standard No. 45, Recommended Practice for Electrical Installations on Shipboard
2.3 ISO Standard: ISO 3046/1 Reciprocating Internal Combustion Engines—Performance
2.4 Code of Federal Regulations: United States Coast Guard Regulations as Published in Code of Federal Regulations No. 46 (CFR 46)

3. Terminology

3.1 Definitions of Terms Specific to This Standard:
3.1.1 diesel engine—a reciprocating or rotary engine in which ignition of the main fuel charge, as it is introduced to the combustion chamber, shall be by the heat of compression of the charge of combustion air, during regular operation of the engine from idle speeds up to full speed, regardless of whether miscellaneous methods to augment such heat of compression are used to facilitate starting of the engine under normal conditions or under low ambient temperature conditions or low intake air temperature conditions. Engines that are designed to operate with a continuously hot spot or bulb or other device to facilitate ignition or combustion, or both, of low cetane fuels, or any fuels slow to ignite or to burn, or both, shall be considered to be diesel engines for purposes of this guide.

3.1.2 engine assembly—contains, but is not necessarily limited to, that apparatus secured to or applied to a basic engine, which is needed to make the basic engine operable and capable of developing its rated power as indicated or to be indicated on the engine nameplate.

3.1.3 fuel map—a chart on which there is displayed a family of curves of various constant rates of specific fuel consumption, each curve of the family being plotted on a grid, the abscissa of which is engine r/min and the ordinate of which is brake horse power or brake mean effective pressure.

3.1.4 medium speed diesel engine—all diesel engines with crank-shaft rotative speeds encompassed by the maximum continuous speed bracket of 400 to 600 r/min (see Appendix X1).

4. Significance and Use

4.1 Comparison of brake horsepower developed and of specific fuel consumption rates from engine to engine may be made by use of data based upon a standard for composition of an engine assembly.

4.2 The purchaser of the engine assembly will be fully advised of the minimum scope of assembly which the purchaser may rightfully expect to be encompassed by a response to a request for quotation and to be delivered in response to a...
purchase order unless the engine builder in the proposal or in the offer to sell has clearly advised otherwise.

4.3 It will be made apparent to the purchaser that additional auxiliary and accessory equipment will be needed to supplement the defined engine assembly when full consideration is given to the application of the engine assembly as a prime mover in a specific vessel.

5. Regulations, Conventions, and Standards

5.1 Specific—The regulations, conventions, and standards to which a commercial marine vessel may be subject in regard to the main propulsion prime movers will vary depending upon the flag of registry of the vessel.

5.2 General:

5.2.1 There may be regulations, conventions, and standards and such applicable international treaties to which the country of registry may subscribe which shall be taken as forming a part of this guide to the extent specified herein and to the extent they shall be deemed applicable to the vessel by the country of registry.

5.2.2 Typical examples applicable to vessels of the United States of America registry are as follows: Institute of Electrical and Electronic Engineers Standard No. 45 (IEEE No. 45); Rules of the American Bureau of Shipping; Rules of the United States Coast Guard as printed in various Part Numbers of Title 46 CFR of the United States of America and formerly commonly known as CG-115 (Marine Engineering Regulations, also known as Sub-chapter F); and CG-259 (Electrical Engineering Regulations, also known as Sub-chapter J).

6. Ordering Information

6.1 Orders for machinery under this guide shall include the following:

6.1.1 ASTM designation, title, and date of this guide.

6.1.2 Quantity, and

6.1.3 Packaging or packing and preservation requirements, or both.

7. Minimum Scope of Assembly

7.1 Each engine assembly to meet this guide shall include the following:

7.1.1 The basic power producing unit or engine, be it that formed by an internal combustion reciprocating engine or by an internal combustion rotary engine.

7.1.2 An engine-mounted intake manifold or manifolds to conduct air for combustion to the basic engine, with such manifold properly secured to the basic engine and properly gasketed for the service intended, which is the efficient conduction of air to the basic engine when it is installed in a marine environment for main propulsion of a vessel.

7.1.3 An engine-mounted exhaust manifold properly insulated (including insulation by use of a water jacket application) as may be required by laws and regulations discussed in 2.2 herein [such as the requirements of USCG-115, paragraph 56.50-1 (k), Parts 50–60, Title 46 CFR].

7.1.4 One or more engine-driven and engine-mounted scavenging air blowers, if required by engine design concept, or one or more single shaft assemblies of an exhaust gas-driven turbine and combustion air blower, or both, if required by engine design concept, to provide a supply of air for scavenging or supercharging, or both, and for basic combustion of the fuel. The single-shaft exhaust gas-driven turbochargers may be engine mounted or separately mounted. The intended method of mounting of such turbochargers shall be clearly described to the prospective purchaser by the engine builder in any response to an inquiry so that the impact on installation cost and responsibility, if any, will be apparent. Turbocharger arrangements, for water-washing or other routine maintenance procedures recommended by the engine builder, shall be provided.

7.1.5 An engineered arrangement of sufficient drilled and tapped holes, properly plugged during shipment, to allow measurement of combustion air and exhaust gas temperatures and pressures at appropriate points in the engine assembly.

7.1.6 One or more air cooler assemblies, if required by engine design concept and power rating, designed to accept all of the air for combustion and scavenging and to cool such air to appropriate temperatures as required by design of the basic engine and by the predicted range of brake horsepower output and concurrent specific fuel consumption rate range. Following the logic of 7.1.4, the air cooler assembly might be offered as a remotely mounted device along with its associated turbochargers. If so, as in the case of the turbocharger, the intended method of mounting shall be clearly described to the prospective purchaser by the engine builder so the impact on installation cost and responsibilities, if any, will be apparent.

7.1.6.1 Such cooler assemblies, commonly referred to as intercoolers or aftercoolers, shall be arranged, if required by overall engine design and application, to limit cooling or to add heat energy to the charge of air for combustion to allow operation of the engine at low continuous power ranges as indicated by the engine builder on a chart of the descriptive curves of performance of the engine (see 4.1 and 4.2).

7.1.7 A jacket water-circulating pump and any other closed circuit fresh water pumps required for operation of the engine. If this pump is not engine mounted and engine driven as parasitic load, the specific fuel rate for the engine on the factory test stand shall be corrected logically and accurately to increase appropriately the specific fuel rate demonstrated on the factory test stand and thereby to allow comparison to other engines (see Section 8).

7.1.8 One or more pressure pumps for main engine lubricating oil supply of each engine unit and, if required by design, for piston cooling service. If this pump(s) is not engine mounted and engine driven as parasitic load, the specific fuel rate for the engine on the factory test stand shall be corrected logically and accurately to increase appropriately the specific fuel rate demonstrated on the factory test stand and thereby to allow comparison to other engines (see Section 8).

7.1.9 A full flow lubricating oil duplex discharge strainer or filter for each engine unit to transmit all oil delivered to the engine by the main lubricating oil pressure pump; or, if required by engine design, lubricating oil supplied to the subordinate and discrete systems of the engine may be supplied via an additional separate duplex lubricating oil strainer. Such strainers need not necessarily be supplied as engine mounted.
7.1.10 An integral, lubricating oil sump, suitable for operation of that engine when installed in a horizontal position but of a limited capacity with respect to total oil charge. Such a sump may be provided with two or more openings which, if left open for connection to a drain, will allow use of a remote oil sump of larger capacity as suggested by the engine builder.

7.1.11 A duplex suction strainer of mesh as recommended by the engine builder to be located on the suction side of the main lubricating oil pressure pumps. Such a strainer need not necessarily be engine mounted.

7.1.12 A force feed cylinder or valve stem lubricator system, or both, if required by engine builder’s design, or by the service intended, or both, or by main engine fuel intended, with both of the latter as stated by the purchaser.

7.1.13 Crankcase pressure relief valves or covers as recommended by the engine builder to meet standards of cognizant marine inspection and classification authority as identified by the purchaser.

7.1.14 An engine-barring device which shall be power driven unless clearly identified to the purchaser by the engine builder as required to be operated by manual effort only.

7.1.15 An engine-mounted flywheel secured to the drive end of the crankshaft complete and sufficient to carry timing marks. If required by drive system arrangement to the reduction gear (or to the propeller shafting if no reduction gear is to be used), the flywheel shall be complete and sufficient to accept mounting of the adjacent flange or coupling component. The machining of the flywheel to accept the adjacent flange or coupling component is part of an engine assembly. The associated set of bolts required shall not be part of an engine assembly.

7.1.16 Propeller Thrust Bearing—NO propeller thrust bearing shall be incorporated into the engine assembly for medium speed main propulsion marine diesel engines except as a result of a specific contractual requirement placed on the engine builder as a result of negotiation with the purchaser.

7.1.17 Governors:

7.1.17.1 The engine builder shall provide the primary engine speed governor. The actuator portion of the governor with its power unit and the speed-sensing portion shall be engine mounted. Nothing in the specification is intended to prevent off-engine location of electro/electronic portions, if any, of the governor system. The required functions or other characteristics, or both, of the governor shall be specified to the engine builder by the purchaser.

7.1.17.2 The engine builder shall provide an overspeed automatic shutdown device or overspeed self-resetting device separate and distinct from the governor of 7.1.17.1 and it shall be engine mounted.

7.1.18 Start-Stop Controls:

7.1.18.1 The engine builder shall provide an engine-mounted system either for complete local control only of the engine or adaptable for local control and remote control from the bridge or the engine room control console, or both. The scope of the remote control features required by the purchaser must be clearly presented to the engine builder in the purchase specification, and requirements of the therein identified cognizant regulatory bodies must be met by the engine builder.

7.1.19 Fuel Oil System:

7.1.19.1 An engine-mounted, engine-driven, fuel oil booster pump (service pump) shall be provided, if required, by the engine builder’s design; however, such a pump may be motor driven for this class of engine and not integral with the engine assembly as shipped. It is, however, to be an item furnished and to be treated as a parasitic load.

7.1.19.2 A duplex final fuel filter or strainer, as specified by the engine builder, shall be supplied by the engine builder. If engine mounted, it shall be properly protected for shipment so that the engine-mounted fuel distribution piping is maintained in a thoroughly clean condition during shipment and installation of the engine.

7.1.20 Engine-Mounted Piping—All required engine-mounted piping for jacket water, raw water, lubricating oil, fuel oil, starting air, control air or hydraulic oil, or a combination thereof, for controls shall be terminated in a workmanlike manner in a flange or other connection arrangement on the engine assembly, and all nonstandard companion flanges or other fittings shall be included by the engine builder.

7.1.21 All special tools not readily obtainable by an owner of a vessel but required for day-to-day maintenance efforts shall be included with the engine assembly as shipped. The engine builder shall provide a fully descriptive list of such special tools as part of a response to any request for a proposal for the machinery.

7.1.22 Spares—No spares are required as part of an engine assembly. However, governmental agencies, the purchaser, the cognizant classification society, and the engine builder all have either authority or interest to see that an appropriate set of spares is provided on board the vessel before final approval to operate is given.

7.1.23 Instrumentation:

7.1.23.1 Engine-mounted instrumentation for local observation. A set of engine-mounted instruments for local observation
shall be provided to meet regulatory body requirements and the requirements of the purchaser. Also, a tachometer drive arrangement shall be provided as well as arrangements to allow measurement of cylinder pressures using a portable pressure measuring device, but not including such device.

7.1.23.2 Engine-mounted sensors for remote readout systems are not part of the engine assembly. However, a special set of instrument wells or drilled, tapped, and plugged openings may be required on the engine-mounted piping and components to accommodate remote reading instruments, and such requirements should be developed separately by discussion between the purchaser and the engine builder.

7.1.24 Cylinder Pressure Relief Valves—Such valves are usually required by the cognizant classification society, whose requirements must be ascertained and met for any specific order for a main propulsion engine.

7.1.25 Drawings—The following should be included in the supply of an engine: engine arrangement drawing including data with respect to engine weight; location of vertical, horizontal, and longitudinal centers of gravity; principal dimensions; size and location of connection points or engine-mounted piping terminations which are to be connected to external piping, tubing, or ducts by others, as well as any special data with respect to such connections; engine bolting and chocking plan; schematic drawings of engine support piping systems showing design restrictions or data important to the installing shipyard.

7.1.26 Manuals and Books—An engine instruction manual covering all components described herein as constituting an engine assembly, and parts books of equal scope, providing information required to operate and maintain the equipment.

7.1.27 Vibration Analysis:

7.1.27.1 The engine builder shall include an analysis of the mass-elastic system of the engine with respect to torsional vibrations. When any or all of the driven equipment system is supplied by others, it is the responsibility of the purchaser to provide, in a timely manner to the engine builder, accurate and complete data with respect to such items of the driven equipment system.

7.1.27.2 Consideration of axial vibration of shafting, lateral shaft vibration, propeller excited vibration, or induced hull vibrations, or a combination thereof, are not in the province of the engine builder’s unique expertise and knowledge to the same extent as is consideration of torsional vibration. If the engine builder is to be required to accept these additional responsibilities, it should be a matter of negotiation and mutual agreement between the purchaser and the engine builder and should be an item in the contract to purchase.

8. Treatment of Parasitic Loads

8.1 General—A recognized and accepted basis, by reference to which a comparison of performance test results may be made, is necessary. The heart of such basis of comparison is consistent and accurate treatment of the parasitic loads of those items of power consuming auxiliary apparatus which are defined in Section 6 to be part of an engine assembly. In summary, such items are:

8.1.1 Scavenging air blowers,
8.1.2 Lubricating oil circulation pumps,
8.1.3 Jacket water-circulating pumps,
8.1.4 Fuel oil service (booster) pumps, and
8.1.5 Engine governor system: component(s) to actuate fuel rack controls.

8.2 If any of the above are required to allow the engine assembly to operate and are not engine driven during such factory tests as are carried out to verify engine brake horsepower and engine specific fuel consumption data, then appropriate, logical, consistent, and accurate treatment is necessary to allow comparison of performance data from engine to engine.

8.2.1 The formula or technique for such correction shall be agreed upon mutually by the potential purchaser and the responding engine builder(s) during the development of a contract to purchase. In the development of such formula, attention should be given to cost of fuel to be burned by the extraneous power source in the proposed vessel and the specific fuel rate of that extraneous source, which, in most cases, will be another prime mover or a ship’s service diesel generator set.

8.2.2 The permutations and combinations are such that detailed treatment is not feasible herein. However, a competent marine engineer can carry on such specific study or review for a purchaser.

9. Performance of an Engine

9.1 The maximum continuous rating (MCR) (see Appendix XI) of an engine shall be shown on the engine nameplate and on all appropriate engine documents. It shall be expressed in brake kilowatts (international) and in British brake horsepower units of 33 000 ft-lb/min. This dual expression of power shall be maintained herein indefinitely until adoption of the designation of power in brake kilowatts is universally and commonly accepted instead of brake horse power (British) or brake horse power (metric). It shall be that power which the engine will deliver continuously, in commercial marine service, at its flywheel (or other coupling flange) at rated revolutions per minute (r/min) when in good operating condition and under standard conditions (see Section 11) with respect to heat content of the fuel burned; and further, under standard atmospheric conditions with respect to ambient air temperature and ambient air pressure at the intake point for combustion air; and further provided that the exhaust back pressure at the exhaust outlet flange provided on the engine by the engine builder does not exceed the limit specified by the engine builder; and further provided that the pressure drop through the air intake system as measured at the air intake flange provided on the engine by the engine builder does not exceed the limit specified by the engine builder.

9.2 At any of the revolutions per minute encompassed by the bracket between maximum continuous r/min and minimum continuous r/min as defined by the engine builder and illustrated on the engine builder’s chart of the descriptive curves of performance of the engine, there shall also exist maximum continuous ratings of lesser values, and special restrictions, if any, must be clearly presented by the engine builder. Performance data provided shall include air borne and structure borne noise data.
9.3 Overload Ratings—If the prospective purchaser requires an overload rating, his request for proposal should clearly present the overload conditions desired to be permissible. Without such clarification, no overload rating is to be expected as a standard of the engine builder. If the engine is ordered and delivered with an overload rating, such rating shall be shown on the engine nameplate and on all appropriate engine documents.

10. Mechanical Efficiency of the Engine Assembly

10.1 The engine builder will identify in his proposal to the purchaser, the mechanical efficiency of the offered engine assembly as that term is used herein, with due allowance made in developing that number, for missing or non-engine driven power consuming parasitic loads, if any, as discussed in the foregoing herein. The engine builder shall later demonstrate in a timely report to the purchaser, based upon the test stand data and sophisticated recording of indicator cards, both applying to that specific engine, that the brake power as measured by the dynamometer is related to the indicated power by that efficiency factor (that is, brake power divided by efficiency in decimal form equals the indicated power).

11. Standard Conditions for Factory Test of Engines for Contractual Purposes

11.1 Standard for Heat Content of Diesel Fuel Used:

11.1.1 Fuel used shall conform to the engine manufacturer’s recommendations.

11.1.2 The reported specific fuel consumption of a liquid fuel engine, as determined by factory test, shall be corrected to reflect the lower calorific value (lower heat value/LHV) of that fuel when it is compared to a standard fuel of a lower calorific value of 42 000 kJ/kg (kilo-joules per kilogram), which lower calorific value may alternately be stated as 10 030 k-cal/kg (kilo-calories per kilogram). When related to practice common in the United States, note that the lower heat value (LHV) of the standard fuel will be found to be 18 057 Btu/lb, which implies an approximate high heat value (HHV) of 19 175 Btu/lb.

11.1.3 Correction formulae shall be as follows:

11.1.3.1 When working with units for LHV in Btu/lb, the specific fuel consumption reported to the purchaser shall be equal to the specific fuel consumption measured on the factory test stand after it is multiplied by a factor, the numerator of which is the LHV in Btu/lb of the fuel used, and the denominator of which is 18 057. Correction for other variations from standard conditions set forth later herein shall be applied to the specific fuel consumption figure derived as described immediately above.

11.1.3.2 When working with units for LHV in SI units of kJ/kg for the lower calorific value, the specific fuel consumption reported to the purchaser shall be equal to the specific fuel consumption measured on the factory test stand after it is multiplied by a factor, the numerator of which is the lower calorific value in kilo-joules per kilogram of the fuel used and the denominator of which is 42 000. Correction for other variations from standard conditions set forth later herein shall be applied to the specific fuel consumption figure derived as described immediately above.

11.2 Standard for Ambient Air Temperature at the Air Intake of the Engine:

11.2.1 The standard for comparison of output of engines in units of brake kilowatts (bkw) or brake horsepower (bhp) shall be 305.37K (32.22°C/90°F). ISO 3046/1 provides for treatment of test results obtained under diverse ambient air temperature conditions in paragraph 10.2 and elsewhere in that standard. Those methods are incorporated into this standard for adjustment of factory test results from actual ambient air temperature conditions to standard ambient air temperature conditions.

11.2.2 The maximum continuous brake horsepower (bhp) discussed in 4.1 preceding herein, and specific fuel consumption, discussed in Section 8 shall be guaranteed for circumstances wherein the temperatures of the air for combustion, as measured at the turbo-compressor inlet, are within a range identified to the purchaser by the engine builder in the proposal, offer to sell, or resulting contract, or a combination thereof.

11.3 Standard for Ambient Air Relative Humidity—Unless otherwise treated in the proposal or contract, the standard for ambient air relative humidity near the air intake of the engine shall be 30 % and shall be used as 0.3 as in ISO 3046/1, wherein provision is made for treatment of test results under diverse ambient air relative humidity conditions. Treatment of test results under diverse relative humidity conditions is provided by ISO 3046/1, page 4, paragraph 10. That method is incorporated into this guide for adjustment of factory test results from actual to standard relative humidity.

11.4 Standard for Ambient Air Total Barometric Pressure—Unless otherwise treated in the proposal or contract, the standard for ambient air total barometric pressure near the air intake of the engine shall be 95.665 kPa (28.25 Hg). Treatment of test results under diverse total barometric pressure conditions is provided by ISO 3046/1, page 4, paragraph 10. That method is incorporated into this guide for adjustment of factory test results from actual total barometric pressure conditions. Note that the tabular solutions in Annex E of ISO 3046/1 are applicable indirectly, if the standard total barometric pressure condition assumption varies from 100 KPa.

11.5 Standard for Temperature of Water to the Intercooler—Unless otherwise treated in the proposal or contract, the standard for temperature of water to the intercooler shall be 305.3K (32.22°C/90°F). ISO 3046/1 provides for treatment of test results obtained under diverse conditions of temperature of water to the intercooler. Such treatment is to be found in paragraph 10.2 and elsewhere in that standard. Those methods
are incorporated into this guide for adjustment of factory test results from actual intercooler water temperature conditions to standard conditions.

12. Turbocharger Performance

12.1 The engine builder shall submit to the purchaser, as a contract data item, a conventional compressor characteristic charge wherein the ordinate scale shall be pressure ratio and the abscissa scale shall be a mass flow parameter. There shall be plotted thereon points of pressure ratio as mass flow varies and the speed (r/min of the turbocharger assembly) parameter is constant. Superimposed on this, there shall be a family of curves or contours of compressor constant “total to total” isentropic efficiency (or alternately “total to static”).

12.1.1 The surge line, with sufficient margin, shall be clearly shown and the operating line, as matched to the engine for a propeller load curve, shall be shown. If this latter graphical superposition indicates a possible surge phenomenon for the proposed propulsion system, the purchaser and the engine builder shall consult together with respect to a solution, in light of the then-existing contract for purchase of the engines.

12.2 If surge conditions are possible, as a result of purchaser’s unique speed/power program for propeller revolutions per minute and propeller pitch incorporated into a control arrangement for a controllable and reversible pitch propeller, the engine builder shall provide an automatic combustion air bypass. Such bypass shall function as a result of joint measurement and integration of air header pressure and engine crankshaft revolutions per minute, such that turbo-compressor surge will be eliminated for a propulsion system, all components of which are in good order. The cost of such system modification shall be negotiated between the engine builder and the purchaser.

12.3 During factory test, surge tendencies will be investigated by sudden reduction of speed and power by percentage reductions and at a time rate to be selected by mutual agreement between the purchaser and the engine builder.

13. Special Fuel Tests

13.1 Medium speed marine propulsion diesel engines, purchased to burn blended or degraded fuels, are not usually subjected to factory test on such fuels before shipment.

13.2 If the purchaser desires such factory test, the requirement therefore and the cost therefore should be a negotiated item of the sales contract. The test agenda for such special test effort shall be negotiated between the engine builder and the purchaser.

13.3 While durability of the engine, if operated on blended or degraded fuels, cannot be demonstrated by a brief factory test, base data on performance characteristics of the engine, when operated on such fuels, should be established and provided to the purchaser as part of any factory test of the engine on such fuels.

13.4 The blended or degraded fuels to be used should be carefully specified and mutually agreed upon between the engine builder and the purchaser. The characteristics of the actual fuel supply used during such tests should be verified by laboratory analysis and provision of those data to the purchaser should be a contractual requirement.

13.5 Contract auxiliary engineered components may be used during such factory tests upon agreement between the engine builder and the purchaser. Such equipment, if used, shall be, as a contractual item, completely cleaned or rehabilitated, or both, before delivery to the purchaser.

13.6 Posttest inspection of the auxiliary or ancillary equipment used, if any, and of the engine assembly, shall be as agreed between the engine builder, the purchaser and the cognizant inspection society or classification society, or both.

13.7 Performance characteristics of the engine to be verified, when operating on blended or degraded fuels, should include, but are not necessarily limited to the following:

13.7.1 Emissions analysis to meet the specified requirements, if any, of the purchaser, and

13.7.2 Brake horse power developed without violation of the engine builder’s limits on such as, but not necessarily limited to, peak firing pressures; preturbine exhaust gas temperatures; injection pressures; air header temperatures; air header pressures; and turbocharger revolutions per minute; all for a spectrum of r/min and power levels.

14. Operating Parameters

14.1 The engine builder shall establish maximum or minimum readings for certain operating parameters for an engine of the model and number of cylinders under consideration, which will not be exceeded, or will be attained in the case of minimum values, when an engine in good operating condition and of that model and number of cylinders, is running and developing any point of power and revolutions per minute to be found within the acceptable operating area as delineated on the engine builder’s performance curves discussed in Section 4.

14.2 Such operating parameter maximums or minimums shall be regarded as contractual, whether embodied in the original contract or provided later as a constructive change to the contract, and shall include, but not necessarily be limited to, the following: brake mean effective pressure; mean piston speed/revolutions per minute of the engine crankshaft; combinations of brake mean effective pressure and revolutions per minute of the engine crankshaft as shown in the engine builder’s performance curves; maximum firing pressures as measured by the device and method recommended by the engine builder; individual cylinder exhaust gas temperature limits and the preturbine temperature limits for the mixture of all cylinder exhaust gases just upstream of the entrance to the turbocharger(s), if the engine is so equipped; maximum lubricating oil temperature in the lubricating oil header or an equivalent to a header; minimum lubricating oil pressure at a point in the system designated by the engine builder; temperature of the combustion air supply in the air inlet manifold; maximum viscosity of fuel at the suction of the fuel injection pump(s); minimum and maximum jacket water temperatures at a point in the system designated by the engine builder; and minimum jacket water pressure at a point in the system designated by the engine builder.
15. Keywords
15.1 brake horsepower of an engine; diesel; diesel engine; direct-reversible engine; engine assembly; engines; fuel map; fuel; internal combustion engine; main propulsion engine; map; marine engine; mass-elastic system; mechanical efficiency of an engine; medium speed diesel engine; parasitic loads; propulsion; surge line; torsional vibration; turbocharger; vibration analysis

APPENDIX
(Nonmandatory Information)

X1. Speed Ranges and MCR Information

X1.1 This guide was directed to be conceived and developed as the first of a group of guides, with follow-on guides to be developed subsequently. To proceed, main propulsion marine diesel engines were divided into classes defined by crankshaft revolutions per minute speed ranges as follows:

<table>
<thead>
<tr>
<th>Speed Range</th>
<th>RPM Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very low speed</td>
<td>80 to 120 r/min</td>
</tr>
<tr>
<td>Low speed</td>
<td>150 to 360 r/min</td>
</tr>
<tr>
<td>Medium speed</td>
<td>400 to 600 r/min</td>
</tr>
<tr>
<td>High speed</td>
<td>700 to 900 r/min</td>
</tr>
<tr>
<td>Very high speed</td>
<td>1200 r/min and higher</td>
</tr>
</tbody>
</table>

The end points between the defined speed ranges are deliberate and represent a strong influence by 60-Hz alternating current electric power generator design characteristics.

X1.2 With respect to MCRs, it must be kept in mind that the power required to develop a given vessel speed through the water, will generally tend to increase over the life of the vessel and will increase markedly as a result of bottom fouling between drydock and bottom cleaning and painting intervals. Therefore, it is not prudent in the general case to install a diesel engine as a main propulsion engine in a situation in which the screw propeller or other thrust-producing device requires the engine to operate at the MCR, when the vessel is new and the hull is clean, to achieve the speed through the water required for the vessel to be economically successful in its proposed trade. System analysis by a competent marine engineer, with respect to propeller, vessel speed, and engine-installed power, should be arranged by the purchaser.
1. Scope

1.1 This specification covers manually operated fueling hose reels for use with collapsible and noncollapsible hose.

1.2 The values stated in inch-pound units are to be regarded as standard. The SI units given in parentheses are for information only.

1.3 The following precautionary caveat pertains only to the test methods portion, Section 12 of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:
   - B 148 Specification for Aluminum-Bronze Sand Castings
   - D 3006 Specification for Polyethylene Plastic Pressure-Sensitive Electrical Insulating Tape
   - D 3951 Practice for Commercial Packaging

2.2 Military Specifications:
   - MIL-S-901 Shock Test, H.I. (High-Impact); Shipboard Machinery, Equipment and Systems, Requirements for
   - MIL-T-16366 Terminals, Electric Lug and Conductor Splices, Crimp Style
   - MIL-H-17902 Hose, End Fittings and Hose Assemblies, Synthetic Rubber, Aircraft Fuels
   - MIL-F-20042 Flanges, Pipe and Bulkhead, Bronze (Silver Brazing)
   - MIL-P-24441 Epoxy-Polyamide Primer

2.3 Military Standard:
   - MIL-STD-130 Identification Marking of U.S. Military Property

3. Classification

3.1 Fueling hose reels shall be of one of the following types as specified:
   - 3.1.1 Type 1—for 150 ft (46 m) of collapsible 2\(\frac{1}{2}\)-in. (65-mm) hose.
   - 3.1.2 Type 2—for 150 ft (46 m) of noncollapsible 1\(\frac{1}{2}\)-in. (38-mm) hose or 100 ft (30 m) of noncollapsible 2-in. (50-mm) hose.
   - 3.1.3 Type 3—for 150 ft (46 m) of noncollapsible 1\(\frac{1}{2}\)-in. (38-mm) hose or for 150 ft (46 m) of collapsible 2\(\frac{1}{2}\)-in. (65-mm) hose.
   - 3.1.4 Type 4—Capacity as specified by purchaser.

4. Ordering Information

4.1 Orders for material under this specification shall include the following information:
   - 4.1.1 Title, number, and year of issue of this specification.
   - 4.1.2 Type of hose reel including hose size and type (see 3.1), length of hose for Type 4).
   - 4.1.3 Whether right- or left-hand reels are required (see 6.5).
   - 4.1.4 Flange inlet thickness and bolt hole dimensions (see 6.7).
   - 4.1.5 Drawings required (see 9.1).
   - 4.1.6 The number of samples to be inspected and tested (see 11.2).
   - 4.1.7 Certification, if required (see 15.1).
   - 4.1.8 Test report, if required (see 15.1).
   - 4.1.9 Applicability of supplementary requirements.

5. Materials and Manufacture

5.1 Except as otherwise specified herein, the hose reels shall be constructed of aluminum, aluminum bronze, or other suitable nonsparking materials. All fittings conveying aromatic fuels through the hose reel shall be made of aluminum bronze in accordance with Specification B 148, copper alloy UNS No. C95300. To prevent deterioration in sea atmosphere, aluminum parts should not contact brass or bronze; however, where such aluminum parts come in contact with brass or bronze, they
shall be protected by adhesive-backed insulating tape, Specification D 3006. All aluminum parts shall be given a coat of epoxy-polyamide primer.

6. Construction

6.1 Reel and Drum Assembly—The hose reel shall be of a durable, rigid construction, as light in weight and compact as practicable. The drum assembly (drum, reel sides, and its reinforcements) shall withstand the hose pull without distortion or collapse and shall be capable of withstanding some sideways hose pull without undue distortions. The construction of the completed drum assembly shall be such that disassembly can be readily accomplished with standard tools. When bolted down to a true flat surface, the shaft and rotating seal centerlines shall be in true alignment and the drum assembly shall turn without binding under a rim pull not to exceed 7 lb (198 kg) with the reel unpressurized. Both ends of the drum shaft shall be supported on ball or roller bearings that shall have provision for easy lubrication. Reels shall be designed so that all bearings, and other corrodible parts, are adequately protected from the weather. Provision shall be made for lubrication of working parts such as bearings or other mating surfaces, and all such parts shall be lubricated before delivery with a lubricant soluble in aromatic fuels. Bearing seals shall be such that the pressure caused by forced lubrication will not bind the shaft.

6.2 Reel Drum—The reel drum may have either smoothly formed flat sides or suitable spoke ribs, so formed as not to damage the hose. The rims of the drum shall provide a good grip for hand rewind.

6.3 Holding Brake—Reels shall be provided with a holding brake to lock the reel in any position.

6.4 Nozzle Clamp—The reel shall be fitted with a device for clamping the hose nozzle securely to the reel to prevent unwinding of the hose and damage to the nozzle.

6.5 Reel Hub Discharge—The reel hub discharge shall be angled to provide a smooth tangential contact of the hose with the reel drum as shown on Fig. 1 and Fig. 2, so that the hose will not kink at the discharge connection. The hub discharge fitting and adapter shall be in accordance with Fig. 2 and Fig. 3 for Types 1, 2, and 3, respectively. Reels shall be right- or left-hand operation and top or bottom wind, as specified. A right-hand, top-wind reel is defined as one that, when looking into the flanged adapter on the discharge fitting when it is at the top of the drum, has its inlet connection on the right-hand side. (Note that a top-wind, right-hand reel and a bottom-wind, left-hand reel are identical.) It shall be possible by turning the discharge fitting around, or by other simple means, to enable the hose to unreel from the bottom of the reel drum to either side of the reel (that is, to make the reel either right hand or left hand) without rotating the reel drum.

6.6 Aromatic Fuels Tight Rotating Joint—The reel shall have an aromatic fuels tight rotating joint between reel inlet
connection and the rotating hub on the reel drum. The rotating joint shall not bind under loading (shall be supported to prevent a bending load being applied), shall have provision for lubrication of moving parts, and shall be capable of easy disassembly for maintenance purposes. The rotating joint shall be tight under the pressure specified in 7.1.

6.7 Inlet Connection—The reel inlet connection shall be flanged, the flange being part of the rotating swivel joint. The flange thickness and bolt hole drilling shall be as specified in the contract or purchase order.

7. Performance Requirements

7.1 Fluid Handling—Reels shall be capable of passing 300 gal/min (0.0189 m³/s) of aviation fuel at a pressure of 150 psi (1.03 MPa) and shall withstand a static fuel pressure of 225 psi (1.55 MPa) without leakage or other signs of weakness. Restrictions and turbulence through the reel shall be kept to a minimum. For this purpose, the fluid path shall be of the 3½-in. (90-mm) size (including rotating swivel joint) and shall use long sweep elbows. The complete fluid-handling section of the reel (that is, from inlet flange to flanged adapter) shall be capable of being removed as a unit without disassembly of the drum or reel sides.

7.2 Reel Hose Capacity—Reels shall be capable of containing lengths of hose, as required, for Types 1, 2, 3, or 4. The hose used shall be either collapsible or noncollapsible as specified.

7.3 Temperature—The reels and the lubricant used shall be capable of satisfactory operation within the range of temperatures from −20 to +120°F (−29 to +49°C).

8. Dimensions, Mass, and Permissible Variations

8.1 The drum diameter shall not be less than the minimum bending diameter of the hose. The general outline and base mounting dimensions and mass shall be in accordance with Fig. 1.

9. Drawings

9.1 When specified in the contract or purchase order, detail assembly drawings shall be provided.

10. Workmanship, Finish and Appearance

10.1 The reel and all parts shall be free of imperfections that may impair serviceability.

11. Sampling

11.1 Lot—For quality conformance, a lot shall consist of all reels of the same type, made at the same factory, of the same materials, of the same construction, and offered for delivery at the same time.

11.2 Sampling for Quality Conformance—Reel samples shall be selected at random from each lot offered for delivery. The number of samples to be tested or inspected shall be in accordance with Table 1, unless otherwise agreed between the
purchaser and the supplier and the quantity shall be specified in the contract or purchase order.

12. Test Methods

12.1 Hydrostatic Test—Hydrostatically test the fluid-carrying portion of the hose reel to 225 psi (1.55 MPa) and hold this pressure for 5 min to test for strength and porosity. Also pressure test the reel by kerosene or synthetic test fluid (solvent) to 120 psi (827 kPa) for tightness. Hold this pressure for 5 min.

12.2 Operating Test—Load-assembled reels selected in accordance with 11.2 with hose and operate by hand to test all functions, fits, clearances, and adjustments.

13. Inspection

13.1 Examination—Sample reels selected in accordance with 11.2 shall be examined to determine conformance with all the requirements of this specification, not involving tests.

14. Rejection

14.1 Defects—Any defective reels in the sample shall not be offered for delivery. If the number of defective reels in any sample exceeds the acceptance number (see Table 1), this shall be cause for rejection of the entire lot.

14.2 Leakage—The reel shall show no leakage or any other signs of weakness after the performance of the tests specified in 12.1 and 12.2.

15. Certification

15.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as required by this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

16. Product Marking

16.1 Each hose reel shall be marked with this ASTM standard number, type of hose reel, reel hose capacity, type of hose, and size of hose.
17. Packaging and Package Marking

17.1 Packaging and package marking shall be in accordance with Practice D 3951.

18.1 Responsibility for Inspection—The supplier is responsible for the performance of all test and inspection requirements as specified herein. The supplier may use his own facilities or a commercial laboratory. The purchaser reserves the right to perform any of the inspections or tests set forth in the specification where such tests or inspections are deemed necessary to ensure supplies and services conform to prescribed requirements.

19. Keywords

19.1 fueling hose reel; hose reel; reel

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements are applicable to Department of Defense procurements and shall apply only when specified by the purchaser in the contract or purchase order:

S1. Referenced Documents

S1.2 Military Standard—MIL-STD-130.

S2. Construction

S2.1 Discharge Fitting—Unless otherwise specified in the contract or purchase order, the discharge fitting shall have an electrical contact at the center to bear against a similar contact button in the hose. From this contact on the discharge fitting, there shall be a continuous electrical path through the center of the hose reel to a terminal on the stationary part of the reel at the inlet connection (see Fig. 1 and Fig. 2). The electrical circuit through the reel shall be electrically insulated from the reel.

S2.2 Electrical Connections—The contact spider shown (see Fig. 2 and Fig. 3) shall be molded nylon, and the assembly shall be in accordance with requirements of MIL-H-17902. The stationary terminal shall be in accordance with MIL-T-16366. Electrical contact button on the discharge fitting shall be as shown on Fig. 2 and Fig. 3.

S2.3 Hose—The fueling hose to be used with these reels will be in accordance with MIL-H-17902.

S2.4 Inlet Connection—Unless otherwise specified in the contract or purchase order, the flange thickness and bolt hole drilling shall be in accordance with Class 250 of MIL-F-20042. The bolt holes shall straddle the vertical centerline of the flange.

S2.5 Primer—All steel and aluminum parts shall be given a coat of epoxy-polyamide primer, see MIL-P-24441.

S3. Shock Tests

S3.1 Shock Tests—The high impact (HI) shock tests shall be Grade A, Class 1, Type A tests in accordance with MIL-S-901. The reel shall be completely assembled (including hose) and shall be mounted on the shock machine in a manner simulating a typical shipboard installation. The number of blows shall be as specified in MIL-S-901.

S3.2 Examination After Shock Tests—Upon completion of the shock test, the equipment shall be carefully examined to determine the extent of any damage to the mechanical components. Examination of the reels shall determine the following:

S3.2.1 The hose shall be unreeled completely and then rolled back on the reel at least five times. Any undue noise or difficulty in operation shall be investigated and the cause determined.

S3.2.2 Any unbalance shall be measured and shall not exceed twice the amplitude obtained before shock.

S3.2.3 A conductivity check shall be made to ensure that the electrical circuit through the reel is intact.

S3.2.4 The fluid-handling section of the reel (between inlet flange and discharge connection) shall be given a hydrostatic test to 225 psi (1.55 MPa) for strength and porosity and a kerosene or test fluid (solvent) test to 60 psi (413 kPa) and 120 psi (827 kPa) for tightness without showing any signs of leakage or other weakness.

S3.2.5 The reels shall be disassembled following the examination after shock tests specified and examined thoroughly for damage. The effects of the shock tests and subsequent check tests on the structure shall be carefully observed and recorded.

S3.3 Failure to Pass Shock Tests—The hose reel shall be considered to have failed to pass the shock tests in the event of the following:

S3.3.1 Breakage of any parts including mounting bolts.

S3.3.2 Appreciable distortion or dislocation of any parts, including mounting feet, bearings.

S3.3.3 Excessive unbalance determined as specified in S3.2.

S3.3.4 Failure to pass the hydrostatic or electrical conductivity tests.

S4. Product Marking

S4.1 Reels shall be marked in accordance with MIL-STD-130. The size of the hose to be used shall be stamped on each reel.

S5. Sampling

S5.1 In addition to the sampling requirements of the basic specification, Table 1 applies for number of samples and rejection level. If the number of defective reels in any sample exceeds the acceptance number, the lots shall be rejected.
Standard Specification for
Pneumatic Rotary Descaling Machines

This standard is issued under the fixed designation F 1348/F1348M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers requirements for pneumatic rotary descaling machines for removal of paint, rust, scale, nonskid deck covering, and other coatings from steel and aluminum structures. These portable machines are intended for use in a marine environment, subject to salt air and spray during use and high humidity during storage.

1.2 The values stated in either inch-pound units or SI units are to be regarded separately as standard. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.3 The following precautionary statement pertains to the test method portion only, Section 12, of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific precautionary statements are given in 17.2.1.

2. Referenced Documents

2.1 ASTM Standards:

B 209 Specification for Aluminum and Aluminum-Alloy Sheet and Plate
D 4417 Test Methods for Field Measurement of Surface Profile of Blast Cleaned Steel
F 1166 Practice for Human Engineering Design for Marine Systems, Equipment, and Facilities

2.2 Federal Standard:

Fed. Std. No. 123 Marking for Shipment (Civil Agencies)

2.3 Federal Specifications:

PPP-B-566 Boxes, Folding, Paperboard

3. Classification

3.1 Descaling machines are available in two types and two classes, as follows:

3.1.1 Type 1, Hand-Held:

3.1.1.1 Class A—inch-pound design, and
3.1.1.2 Class B—SI metric design.

3.1.2 Type 2, Deck-Supported:

3.1.2.1 Class A—inch-pound design, and
3.1.2.2 Class B—SI metric design.

3.2 Hubs for use with descaling machines are available in four classes, as follows:

3.2.1 Class A—Nonmetallic, nonwoven, noncontaminating,
3.2.2 Class B—Peening hub for aluminum surfaces,
3.2.3 Class C—Metallic hammer type for steel surfaces, and
3.2.4 Class D—Metallic cutter type for steel surfaces.

4. Ordering Information

4.1 Orders for material under this specification shall include the following:

---

<sup>1</sup> This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.

<sup>2</sup> Annual Book of ASTM Standards, Vol 02.02.

<sup>3</sup> Annual Book of ASTM Standards, Vol 06.02.

<sup>4</sup> Annual Book of ASTM Standards, Vol 01.07.

<sup>5</sup> Available from Standardization Documents Order Desk, Bldg 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

<sup>6</sup> Available from American Bureau of Shipping, ABS Plaza, 16855 Northchase Dr., Houston, TX 77060.

<sup>7</sup> Available from Uniform Classification Committee Agent, Tariff Publication Officer, Room 1106, 222 S. Riverside Plaza, Chicago, IL 60606.
4.1.1 Title, number, and date of this specification,
4.1.2 Quantity,
4.1.3 Type and class required (see Section 3),
4.1.4 Test and inspection certification requirements, if applicable (see Section 15),
4.1.5 Test report requirements (see Section 15),
4.1.6 Technical manual requirements (see Section 16),
4.1.7 Special marking required (see 18.3),
4.1.8 Level of preservation, packaging, packing, and marking required (see Section 17 and Supplementary Requirements), and
4.1.9 Lubrication requirements of Supplementary Requirements, if applicable (see Section S3).

5. Materials and Manufacture

5.1 Asbestos and Cadmium:
5.1.1 Material used in the machines, or in any components, accessories, repair parts, tools, and packing and packaging shall be free of asbestos and cadmium.
5.2 Metal Parts—Metal parts shall be corrosion resistant or treated to resist corrosion.

6. Mechanical Properties

6.1 The machines shall be powered by an air motor and shall accept each of the rotary hubs (see 6.9).
6.1.1 *Type 1*—The Type 1 machine shall be a hand-held unit having a minimum of two handles, one of which shall house the trigger mechanism. The trigger mechanism shall be of the spring-loaded “dead man” type and shall immediately shut off air flow to the motor when released. The arrangement of the handles and trigger mechanism shall permit right- or left-handed operation with equal ease. The direction of rotation of the hubs shall tend to propel the machine in the forward direction, away from the operator. The Type 1 machine shall remove coatings to within 1/4 in. [6 mm] of bulkheads, coamings, decks, and other immovable objects.
6.1.2 *Type 2*—The Type 2 machine shall be a deck supported unit with a T-shaped operating handle. The operating handle shall be adjustable for height, rigid and strong enough to operate the machine without bending, and long enough to allow any operator with the percentile body dimensions specified herein (see 6.2) to operate the machine while walking behind it in a natural walking position. The air hose connection and trigger mechanism shall be located on the T-handle. The trigger mechanism shall be of the spring-loaded “dead man” type and shall immediately shut off air flow to the motor when released. The handle shall detach or be adjustable to and lockable in the vertical position for storage. The machine shall be provided with at least two wheels used to move the machine. With the handle, air hose and each of the abrasive hubs attached, the machine shall sit level on the deck with the abrasive hubs in contact with the deck and not interfere with deck coating removal process. The machine shall easily propel itself or be propelled by the operator across the deck without overstressing the operator (see 6.2). The Type 2 machine shall remove deck coating to within 1 1/2 in. [40 mm] of the bulkheads, coamings, and other immovable objects.

6.2 Human Engineering—The machines shall be in accordance with the human engineering criteria of Practice F 1166 except where such requirements conflict with the requirements of this specification. The machines shall incorporate the maintainability requirements of Practice F 1166 and shall permit safe and efficient performance of operation and maintenance by the fifth percentile female to the ninety-fifth percentile male, as defined in Practice F 1166. Clearance shall be provided around each component, part or control so that an individual with aforementioned percentile body dimensions and physical capabilities can safely operate, maintain, remove, or replace any item using normally available tools and test equipment. The controls required for operation and maintenance shall be in accordance with Practice F 1166 and shall not require operator forces to exceed the strength limitations listed therein.

6.3 Interchangeability—Component parts and assemblies peculiar to each type and class of machine from any one manufacturer shall be fully interchangeable. Such interchangeability shall not require any alterations or modifications.

6.4 Dimensions and Weight—The machines, fully assembled with guards; debris collector attachment (less hoses and collection container); and with operating handles (Type 2) locked in its operating position; fully lubricated and ready in all aspects for operation (less air hose and filter, evaporator and lubricator attachments) shall not exceed the maximum dimensions and weight shown in Table 1.

6.5 Air Motor—The machines shall be driven by air motors that operate on the minimum air supplies as shown in Table 2.

6.6 Guards—Machines of both Type 1 and Type 2 shall be provided with guards that protect the operator from inadvertent contact with moving parts and prevent uncontrolled scattering of chips or scale removed by the machine. These guards shall not interfere with the performance of the machine throughout the machine’s useful life, unduly decrease any of the hub’s physical dimensions or wear, or interfere with changing of the hubs. The guards/rotary hub containment shall be constructed to accommodate a debris collection system.

6.7 Air Connections—Air connections for both Type 1 and Type 2 machines shall be of the quick disconnect type. The locations of the air connection shall be such that the hose does not interfere with operation of the machine or the operator. The inside diameter of the connections shall be in accordance with Table 3.

6.8 Lubrication—Lubrication fittings shall be installed so that lubrication can be accomplished without disassembly of the machine (see 6.2). Lubrication materials shall be high-temperature lubricating oil or high-performance grease.

6.9 Hubs:

6.9.1 Hubs for each type and class of machine shall clean a path of width not less than that shown in Table 4. Hubs for each type, class, and manufacture of machine shall be interchangeable with hubs of any other machine of the same type, class,
and manufacture, using only the normally available tools (see 8.1.2) for the interchange.

6.9.2 Hubs shall be of the following classes, classified by intended composition, function, and service life, as follows:

6.9.2.1 Class A Hub—The Class A hub shall be nonmetallic, nonwoven, noncontaminating, and shall remove paint, rust, or scale. The Class A hub shall feather the edge of a painted surface in a smooth taper from the painted aluminum surface to bare metal, and shall not remove, erode, or groove metal surfaces. The Class A hub shall have a minimum service life of 8 h.

6.9.2.2 Class B Hub—The Class B hub shall remove paint, rust, or scale and shall peen the aluminum surface to a profile of 1.0 to 3.0 mils [0.0025 to 0.0076 mm]. The Class B hub shall have a minimum service life of 50 h.

6.9.2.3 Class C Hub—The Class C hub shall be a metallic hammer type assembly and shall remove paint and nonskid covering on steel surfaces. The Class C hub shall operate over protrusions or obstructions on the deck surface, such as bolts or padeyes, up to a height of 1 in. [25 mm], without damage to the hub or machine. The Class C hub shall have a minimum service life of 100 h.

6.9.2.4 Class D Hub—The Class D hub shall be a metallic type cutter assembly that removes paint, rust, scale, and nonskid deck coverings on steel surfaces. The Class D hub shall have a minimum service life of 30 h.

7. Performance Requirements

7.1 Removal Rate—The minimum removal rate when tested in accordance with Section 12 shall be as specified in Table 5 and Table 6.

7.1.1 Type 1 Machine—See Table 5.

7.1.2 Type 2 Machine—See Table 6.

7.2 Stability:

7.2.1 Type 1 Machine—The assembled Type 1 machine shall operate at any angle from the horizontal to vertical (including the overhead) without loss of power or descaling efficiency.

7.2.2 Type 2 Machine—The assembled Type 2 machine shall operate without loss of power and descaling efficiency and without tipping when inclined at an angle of 15° from the horizontal in any direction.

8. Attachments

8.1 The machine shall be furnished in kit form, with each kit containing the following items besides the basic machine:

8.1.1 One Class A hub,
8.1.2 One Class B hub,
8.1.3 One Class C hub,
8.1.4 One Class D hub,
8.1.5 One air hose with fittings,
8.1.6 One hub-changing tool (or tool set),
8.1.7 One debris collector,
8.1.8 One carrying case, and
8.1.9 One in-line filter/evaporator/lubricator.

8.1.10 Air Hose—Air hoses shall be ¾ in. [10 mm] for Type 1 machine and ½ in. [19 mm] for Type 2 machine with quick-disconnect connections and an air shutoff valve that shall immediately shut off the air when the hose is disconnected. The hose for the Type 1 machine shall be 50 ft [15 m] long and the hose for the Type 2 machine shall be 100 ft [30 m] long.

8.1.11 Hub Changing Tool—A standard commercially available tool for changing hubs shall be provided. The tools shall not be unique to a specific supplier.

8.1.12 Carrying Case—The carrying cases for Type 1 and Type 2 machines shall be corrosion-resistant, fire-resistant, high-impact material, strong and rigid enough to transport the machine and its accessories. The carrying case shall rigidly hold all accessories with the exception of hoses, without deformation or breakage, and shall be less than 24 in. [610 mm] wide. The carrying case shall also hold the machine’s handle when the handle is disconnected.

8.1.13 Debris Collector—Both Type 1 and Type 2 machines shall be capable of attaching a debris collecting device that will collect a minimum of 95 % of the debris created.

8.1.14 In-Line Filter/Evaporator/Lubricator—A filter to remove air system debris, an evaporator to remove moisture, and a lubricator to continually lubricate the machine or a combination unit shall be installed to ensure satisfactory long-term...
use in a marine environment. These units shall not hinder the operator’s ability to handle and use the machine.

9. Number of Tests

9.1 A first unit shall satisfactorily pass the tests in Section 12 before production units are offered for delivery.

10. Specimen Preparation

10.1 Test Plates—Steel test plates shall be in accordance with the American Bureau of Shipping (ABS) Rules for Building and Classing Steel Vessels. Aluminum test plates shall be in accordance with Specification B 209, Alloy 5086. Test plates shall be at least \( \frac{1}{2} \) in. [6 mm] thick. Area of plates used in performance tests shall be at least equal to the area that would be cleaned in 10 min at the minimum hourly removal rate for the machine and hub being tested.

10.2 Test Surface Preparation:

10.2.1 Test plates shall be prepared for the performance tests as specified herein. Coatings shall be prepared for application in accordance with manufacturer’s instructions.

10.2.1.1 Painted Surfaces—The steel or aluminum surface shall be cleaned to a uniform white appearance with a minimum surface profile of 1.0 to 3.0 mils [0.025 to 0.075 mm]. The surface shall be dry and free of all contaminants. Two coats of an epoxy-polyamide primer followed by two coats of epoxy paint shall be applied, each coat approximately 3 mils [0.075 mm] thick. Minimum time between coats and between application of last coat and commencement of test shall be 24 h each.

10.2.1.2 Rusted Steel Surfaces—The steel surface shall be wet and exposed to air until it exhibits a complete, uniform coating of rust. A saline solution may be applied to speed rusting. The rusted surface shall be allowed to air dry before testing.

10.2.1.3 Surface with Nonskid Coating—The surface shall be cleaned to a uniform white appearance with a minimum surface profile of 1.0 to 3.0 mils [0.025 to 0.075 mm]. The surface shall be dry and free of all contaminants. One coat of an epoxy-polyamide primer approximately 3 mils [0.075 mm] thick and one coat of a nonskid coating compound shall be evenly applied. The nonskid compound shall be a two part synthetic resin compound, consisting of the basic resin plus aggregate and hardener. The nonskid after curing shall have a minimum average thickness of 30 mils [0.75 mm]. Minimum time between coats and between application and drying/curing of last coat and commencement of test shall be 24 h.

11. Responsibility for Tests and Inspections

11.1 Unless otherwise specified in the contract or purchase order, the manufacturer is responsible for the performance of all inspection and test requirements specified in this specification. Except as otherwise specified in the contract or purchase order, the manufacturer may use his own or any other suitable facilities for the performance of the inspection and test requirements unless disapproved by the purchaser at the time the order is placed. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification when such inspections and tests are deemed necessary to ensure that the material conforms to prescribed requirements. Each party has the right to witness tests performed by the other party.

12. Test Methods

12.1 Service Life Test—Conduct service life tests on an uncoated steel test plate (see 11.1). Operate the machine and each hub in full contact with the test plate for the minimum service life specified herein for the particular hub being tested. The test may be continuous or may consist of shorter time periods adding up to the applicable service life. Breaks between the shorter test periods are limited to 1 h followed by 1 h or more of operation (simulation of daily usage). Fracture, bending, or other failures affecting useability of any component of the machine or hub constitutes a defect. The service life test precedes the performance tests for each hub.

12.2 Performance Tests:

12.2.1 Test each hub on the test surfaces required in Table 7. Use the machine for 10 min. Measure the area of the surface that is cleaned to bare metal in 10 min and multiply by six to determine the hourly removal rate. Failure to attain an hourly removal rate at least equal to the minimum removal rate stated in Section 7 constitutes a defect.

12.2.1.1 Class A Hub—After each performance test with the Class A hub, examine the metal surface for scoring, gouging, or erosion of metal. Presence of any of these conditions constitutes a defect.

12.2.1.2 Class B Hub—After each performance test with the Class B hub, test the metal surface in accordance with Test Methods D 4417 to determine its surface profile. Failure to produce a surface profile between 1.0 to 3.0 mils [0.0025 to 0.0076 mm] constitutes a defect.

12.3 Stability—Test the Type 1 machine on horizontal (including the overhead) and vertical surfaces at no load and full load. Conduct stability operation test on the Type 2 machine inclined at an angle of 15° in any direction from the normal horizontal position and at both no load and full load. For the Type 2 machine, loss of power or tipping constitutes a defect.

12.4 Precision and Bias—No statement is made about either the precision or bias of these test methods since the result merely states whether there is conformance to specified operating requirements.

13. Inspection

13.1 Visual Inspection—A visual inspection shall be made of each machine for the following defects:

13.1.1 Any part or component not as specified, missing, or damaged,

13.1.2 Hubs not interchangeable, and

13.1.3 Air hose failing to connect to machine.

14. Rejection

14.1 Any defect shall be cause for rejection.

15. Certification

15.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

16. Technical Manuals

16.1 Unless otherwise specified in the purchase order or contract (see 4.1.6), the manufacturer’s standard operation and maintenance manual shall be provided with each unit. As a minimum, the technical manual shall contain information regarding unpacking, inspection, assembly, operation, controls, lubrication, routine maintenance, replacement of parts, and a parts listing.

17. Product Marking and Labeling

17.1 Identification Marking—Each machine shall bear a manufacturer’s nameplate securely attached to the outside of the housing citing the manufacturer’s name, contract number, and model number of the machine.

17.2 Warning Label:

17.2.1 The machine shall be provided with a warning label, firmly affixed in a prominent location. The characters shall be not less than \(\frac{3}{8}\) in. \([9.5\, \text{mm}]\) high and in accordance with Practice F 1166. The label shall state:

WARNING

DO NOT OPERATE WITHOUT HEARING
AND EYE PROTECTION
EAR AND EYE DAMAGE MAY RESULT

17.2.2 The word “WARNING” shall be printed in yellow on a black background. The message below it shall consist of black letters on a yellow background. Similar warning or caution label plates shall be affixed for other situations that would create a personnel hazard or equipment damage.

18. Packaging and Package Marking

18.1 Preservation and Packaging—Preservation and packaging shall provide adequate protection against corrosion, deterioration, and physical damage during shipment and, unless otherwise specified, may conform to the supplier’s commercial practice when such meets these requirements. Each machine shall be complete, fully lubricated, and ready to operate upon delivery (some assembly is allowed). Technical manuals furnished with basic equipment shall be packaged in sealed, waterproof wrapping.

18.2 Packing—Packing shall be accomplished in a manner that will ensure acceptance by common carrier at the lowest rate and will afford protection against physical or mechanical damage during shipment. The shipping containers or method of packing shall conform to the Uniform Freight Classification Rules and Regulations or other carrier regulations as applicable to the mode of transportation and unless otherwise specified, may conform to the supplier’s commercial practice when such meet these requirements.

18.3 Marking—Unless otherwise specified (see 4.1.7), shipment marking information shall be provided on interior packages and exterior shipping containers as follows:

18.3.1 For Commercial Procurements—in accordance with the contractor’s commercial practice,

18.3.2 For U.S. Government Agencies, Except Military—in accordance with Fed. Std. No. 123,

18.3.3 For U.S. Military Agencies—in accordance with MIL-STD-129.

19. Keywords

19.1 air hose; air motor; descaling; hose; air; hub; machine; pneumatic

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract or order.

S1. Referenced Documents

S1.1 Military Standard—MIL-STD-147.

S1.3 Federal Specifications—PPP-B-566, PPP-B-601, PPP-B-621, PPP-B-636, PPP-B-640, and PPP-B-676.

S2. Packaging

S2.1 Disassembly and Matchmarking—Item disassembly shall be the minimum necessary to make accessible for cleaning, drying, and preservation of machined and critical surfaces. Removal of items or projecting parts which will facilitate protection of the equipment or item from damage, pilferage, loss, or reduce package volume, is permitted where such removal will not affect permanent settings or alignments, and where the removed items can be readily reassembled at the installation site without the need for special tools. Removed items shall be matchmarked to facilitate reassembly. Removed items shall be tagged and marked with the tags attached to each mating item.
S2.2 Carrying Case—Each machine shall be packaged in its carrying case such that chaffing or contact of machine parts is prohibited. All accessories shall be packaged in packages conforming to MIL-B-117, Type 1, Class C, Style 2, and packed in a carrying case.

S2.3 Packaging Materials:

S2.3.1 Unit Containers—Unit containers shall conform to any one of the following specifications. Selection of the container and options provided in the applicable container specification shall be at the suppliers option:

<table>
<thead>
<tr>
<th>Specifications</th>
<th>Container</th>
</tr>
</thead>
<tbody>
<tr>
<td>PPP-B-566</td>
<td>Box, paperboard, folding</td>
</tr>
<tr>
<td>PPP-B-636</td>
<td>Box, fiberboard</td>
</tr>
<tr>
<td>PPP-B-676</td>
<td>Box, paperboard, setup</td>
</tr>
</tbody>
</table>

S2.3.2 Box closure shall be in accordance with the applicable box specification or appendix thereto. Closure, waterproofing, and reinforcing as applicable for fiberboard boxes, when selected, shall be as follows: domestic grade in accordance with Method 1 using pressure sensitive, reinforced, strippable tape; weather-resistant grade in accordance with Method 5.

S2.4 Storage Box—Each carrying case shall be placed in a container as specified in S2.3.1. Fiberboard pads shall be provided to obtain a snug fit and to protect all projecting items (hardware, handle) from damage during handling, shipment and storage.

S2.5 Packing—Packing shall be Level A, B, or C as specified.

S2.5.1 Levels A and B—Machines shall be packed in containers as specified (see S2.5.1.1). When the unit container selected is of the weather-resistant grade, no further overpacking is required.

S2.5.1.1 Containers—Containers shall be in accordance with any of the specifications listed in Table S2.1. Selection of the container and options provided in the applicable specification shall be at the suppliers option.

S2.5.1.2 Closure, Reinforcing, and Waterproofing—Shipping containers shall be closed, strapped, or banded in accordance with the applicable container specification or appendix thereto. For Level A packing, fiberboard boxes shall be reinforced with pressure-sensitive reinforced, filament tape, or nonmetallic banding as specified in the appendix, to the applicable fiberboard box specification instead of steel strapping.

S2.5.2 Level C—Products shall be packed in containers at the lowest applicable level acceptable to the common carrier and that will ensure safe delivery of contents at the Naval receiving activity in a satisfactory condition for use. Containers, packing, and method of shipment shall comply with the ABS Uniform Freight Classification Rules and Regulations or other carrier as applicable to the mode of transportation.

S2.6 Palletized Unit Loads—When applicable, products packaged as specified shall be palletized in accordance with MIL-STD-147.

S2.7 Hose—Hose shall be prepared for shipment in accordance with MIL-P-775 for the levels of protection specified.

S3. Lubricants

S3.1 All lubricants shall be in accordance with MIL-L-17331 or DOD-G-24508.

S4. Inspection of Packaging

S4.1 Sample packs and the inspection of preservation, packing, and marking for shipment and storage shall be in accordance with Sections 16 and 2 and the documents specified herein.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for
Pressure-Reducing Valves for Water Systems, Shipboard

This standard is issued under the fixed designation F 1370; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers self-contained, globe style, pressure-reducing valves for use in water systems of shipboard installations. These valves are limited to discharge pressure settings of 200 psig (1379 kPa) and below.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 The following precautionary caveat pertains only to the tests portion, Section 8, of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3. Terminology

3.1 Definitions of Terms Specific to This Standard: Descriptions of Terms Specific to This Standard:

3.1.1 accuracy of regulation—the amount by which the downstream pressure may vary when the valve is set at any pressure within the required set pressure limit and is subjected to any combination of inlet pressure, flow demand, and ambient temperature variations within the specified limits.

3.1.2 design pressure and temperature—the maximum pressure and temperature the valve should be subjected to under any condition; these are the pressure and temperature upon which the strength of the pressure-containing envelope is based.

3.1.3 hydrostatic proof test pressure—the maximum test pressure that the valve is required to withstand without damage; valve operation is not required during application of this test pressure, but the valve must meet all performance requirements after the pressure has been removed.

3.1.4 lockup pressure—the outlet pressure delivered by a pressure-reducing valve when the flow is reduced to zero; lockup pressure is always greater than set pressure, and in actual practice it may vary with the specific valve design, tolerances, method of sensing downstream pressure, and piping configurations.

3.1.5 nominal pressure—the approximate maximum pressure to which the valve will be subjected in service under normal conditions.

3.1.6 set pressure—the downstream pressure that the valve is set to maintain under a given set of operating conditions (that is, inlet pressure and flow); the valve should ideally be set at downstream pressure approximately equal to the midpoint of the set pressure limits (defined in 3.1.7).

3.1.7 set pressure limits (set pressure adjustable range)—the range of set pressure over which the valve can be adjusted while meeting the specified performance requirements.

4. Classification

4.1 Valves shall be of the following types and pressure ratings, as specified (see Section 5 and 6.1.21).

4.1.1 Type I—Pressurized spring chamber, and

4.1.2 Type II—Unpressurized spring chamber.

4.2 Pressure Ratings—Valves shall have nominal inlet pressure ratings of 150 or 250 psig (1034 or 1724 kPa), or as specified (see 6.1.21).

5. Ordering Information

5.1 Ordering documentation for valves in accordance with this specification shall include the following information, as required, to describe the equipment adequately.

5.1.1 ASTM designation and year of issue,

5.1.2 Valve specification code (see 6.1.21),

5.1.3 Quantity of valves,

5.1.4 Set pressure required,

5.1.5 Set pressure limits, if not listed in 7.1.4,

5.1.6 Face-to-face dimensions for valves, if not listed in Table 1,

5.1.7 Regulation accuracy required, if other than as given in 7.1.5,

5.1.8 When a choke feature is required (see 6.1.2),

5.1.9 When tailpieces and nuts are required (see 6.1.15),

5.1.10 Capacity requirement of valves, if not listed in Table 2 (see 7.1.6), and

5.1.11 Supplementary requirements, if any (see S1 through S4).

6. Valve Construction and Coding

6.1 Valves shall incorporate the design features specified in 6.1.1 through 6.1.21.

6.1.1 Materials of Construction—Materials shall be as specified in Table 3. All materials shall be selected to prevent corrosion, galling, seizing, excessive wear, or erosion where applicable. Cadmium plating is prohibited.
6.1.2 General Requirements—Valves shall be self-contained, spring-loaded, direct-operated, pressure-reducing valves incorporating a balanced valve element. Reduced pressure (not to exceed 200 psig (1379 kPa)) shall be sensed by a diaphragm and compared with a reference spring load. Any force imbalance shall be transmitted directly to and positively reposition a single-seated valve element to limit the set point error within the limits specified in 7.1.5. Type I valves shall be valves in which the spring chamber in combination with the body and bottom cap forms a pressure-containing envelope capable of withstanding the full hydrostatic proof test. These valves shall be specified for special applications in which it is necessary to contain the line media in the event of a failure that subjects the spring chamber to full inlet pressure. The spring chamber assembly need not be leakproof; however, it shall contain line media at hydrostatic proof test pressure without structural failure and shall limit external leakage to a small seepage (in drip form) past the adjusting screw threads and spring chamber joint. Type I valves shall also incorporate a choke feature on the poppet to limit capacity in the event of a diaphragm failure, where specified (see Section 5). Type II valves shall be valves in which the spring chamber does not form part of the pressure-containing envelope.

6.1.3 Pressure Envelope Rating—The nominal inlet (see 3.1.5), design (see 3.1.2), and hydrostatic proof test (see 3.1.3) pressures for the pressure-containing envelope (body, spring housing, and bottom cap) shall be as specified in Table 4. The design temperature (see 3.1.2) is also given in Table 4.

6.1.4 Body Passages—Body passages shall produce gradual changes in flow direction so as to reduce any effects of concentrated impingement and 90° turns. In portions of the valve subject to velocity increases and flow direction changes, such as immediately downstream of the seat, the 90° impingement against the walls at close range shall be avoided. The body cavity downstream of the seat shall present a high angle (70 to 90°) of incidence to the issuing jet. At points at which direct impingement at close range does occur and cannot be eliminated, the section thickness shall be increased substantially to provide adequate material to withstand the additional erosive effect.

6.1.5 Diaphragm Construction—The main diaphragm shall be clamped between flanges on the body and spring chamber to ensure a leaktight flange seal. The flange faces shall have sufficient width, and all edges in contact with the diaphragm shall be properly chamfered or rounded to prevent cutting or tearing of the diaphragm. The valve and diaphragm shall withstand a pressure differential across the diaphragm of twice the highest set pressure or 200 psig (1379 kPa), whichever is greater, for Type I valves. For Type II valves, this pressure differential shall be as follows: For valves of sizes up to 2 in.

<sup>a</sup>When threaded parts made of nickel-copper alloys, such as seat ring, guide bushings, and so forth are screwed into a bronze body, the threads on these parts as well as the mating threads in the body shall be given a corrosion-inhibitive coating (polysulfate chromate elastomer) per MIL-S-81733 to minimize the galvanic and crevice corrosion of threads.

<sup>b</sup>The guiding surfaces on the stem (guide posts) and the guide bushings shall have a minimum hardness differential of 50 Brinell hardness numbers. The softer of the two guiding surfaces shall have a minimum hardness of 200 Brinell.

<sup>c</sup>Hardness of the disc insert is to be Shore 75° ±5.

and roundness requirements for all surfaces that establish main valve alignment shall ensure parallel disc/seal contact and free valve movement without sticking or binding in the assembled valve. The valve shall be designed so that these alignment requirements are maintained with interchangeable parts and under any additive tolerance (stackup) condition without requiring machining after assembly of the body and bottom cap. The bottom cap/body joint shall ensure, by positive means, proper alignment of the lower guide bushing to ensure repeated correct reassembly. The bottom cap shall be located by body guiding, that is, a close tolerance fit between machined diameters on the body and bottom cap rather than depending on studs or bolts for location. Where the bottom cap/body joint is of flanged construction, proper parallel alignment of the lower guide bushing shall be assured by metal-to-metal makeup of at least a portion of the flange faces, which shall be machined true. The finish of the guiding surfaces shall have a roughness height rating (RHR) of 32 or better. The guiding surfaces shall not be used as sealing surfaces.

6.1.7 Valving Element Balance—The valve element shall be completely pressure balanced when in the seated position. The dynamic seal shall be accomplished by use of either a diaphragm or a fully retained U-cup or O-ring. Where a U-cup
or O-ring is used, the surface moving against the seal shall have a finish of RHR 16 or better and shall not be used for guiding the stem.

6.1.8 Seat Ring—A replaceable threaded seat ring (or a piston chamber for valves with the cage construction design) shall be provided so that it can be replaced with hand tools (see 6.1.18) and does not require machining after assembly. The seat ring shall shoulder against the body to provide a positive pressure-tight joint in which the threads are not used to seal. Where a nonmetallic sealing element is used, a precision-dimensioned gland or cavity shall be provided in either the body or seat ring to ensure proper and controlled retention of the sealing element.

6.1.9 Bolting Requirements—The spring chamber/body flange and bottom cap/body flange (if applicable) shall be secured by one of the following methods:

(1) Bolts threaded the entire length and fitted with a nut on each end. Threads on bolts and nuts shall have a Class 2 fit in accordance with ANSI B1.1.

(2) Tap-end studs with a Class 5 interference fit at the tap end and a Class 2 fit at the nut end. The fit shall be in accordance with ANSI B1.12.

(3) Hexagonal head bolts or cap screws.

The bearing surfaces of nuts and bolts and their respective mating surfaces on the valve shall be cast or forged smooth and true or be finish-machined. The bottom cap/body joint may have either a flanged construction, in accordance with the above, or a threaded construction. A properly retained gasket or O-ring shall be provided to seal against external leakage.

6.1.10 Spring Construction—Springs shall not be fully compressed under any normal operation or adjustment of the valve. Spring ends shall be squared and ground.

6.1.11 Set Pressure Adjustment—The set pressure (see 3.1.6) shall be adjustable with the valve under pressure. The set pressure shall be increased by the clockwise rotation of the adjusting device. The adjusting device shall be provided with a locknut and cap or other suitable means to guard against an accidental change in set point. Set pressure shall be adjustable through a range of not less than 75 to 125% of the mid-range set pressure with the installed spring without replacing any internal parts (see Section 5).

6.1.12 Threads—Threads shall conform to ANSI B1.1. Provisions shall be incorporated, where necessary, to prevent the accidental loosening of threaded parts. Bolting shall generally have a Class 2 fit, in accordance with ANSI B1.1. The material, hardness, finish, and clearances of mating threaded parts shall prevent galling of the threads. Pipe threads shall not be used for main connections, but they may be used for low-stressed internal parts, such as attachment of a pitot tube. When required in Table 3, threads shall be coated.

6.1.13 Interchangeability—Parts having the same manufacturer’s parts numbers shall be directly interchangeable with each other with respect to installation and performance without requiring selection or fitting. In no case shall parts for a given valve be physically interchangeable or reversible unless such parts are also interchangeable or reversible with regard to function, performance, and strength.

6.1.14 Accessibility—Adjustment and repair of the valve shall be possible without removal from the line.

6.1.15 End Connections—Valve ends shall be in accordance with the applicable documents listed in Table 5. The valve end connection type shall be as specified (see Section 5 and 6.1.21). Unless otherwise specified in the ordering information (see Section 5), valves with union-ends shall be supplied with the male threadpieces only, without the tailpieces and the union nuts. Flanges and union-end thread pieces shall be cast or forged integral with the valve body. Inlet and outlet connections shall be of the same size and pressure rating.

6.1.16 Face-to-Face Dimensions—Face-to-face dimensions for valves shall be in accordance with Table 1. Face-to-face dimensions for valves not covered in Table 1 shall be as specified (see Section 5). For union-end valves, the face-to-face dimension is defined as the distance between the parallel faces of the threaded ends of the valve body.

6.1.17 Body Configuration—Valves shall have globe configuration with in-line inlet and outlet ports. Pressure lines, including the reduced pressure sensing line, shall be internally ported in the body.

6.1.18 Special Tools—Special tools shall not be required for installing or removing the valve from the pipe line. Special tools may be furnished for servicing valve internals if it can be demonstrated that use of the special tool saves labor or time. Special tools are defined as those tools not listed in the Federal Supply Catalog.

6.1.19 Painting—Except for the case of aluminum alloys, painting of the external surfaces of nonferrous metal castings, pipings, or other parts is not required. Parts made of aluminum alloys shall be given one coat of pretreatment per DOD-P-15328, Formula 117, and one coat of primer per TT-P-645, Formula 84.

6.1.20 Welding and Brazing—Welding and brazing shall be performed in accordance with MIL-STD-248 and MIL-STD-278.

6.1.21 Valve Specification Coding—Basic valve design features shall be specified and recorded using the valve coding system shown in Fig. 1. The valve specification code contains six fields of information, which describe the construction features of the valve. These six fields are each further assigned their respective codes per Tables 6-10.

7. Performance Requirements

7.1 All valves shall meet the following requirements:

7.1.1 Springs—Springs shall not exhibit a set in excess of the calculated allowable set (see S1.1.3).

7.1.2 Hydrostatic Proof Test—The pressure-containing envelope shall withstand internal hydrostatic pressure of 1.5 times the design pressure (see Table 4 and S1.1.4).

7.1.3 Seat Tightness—The pressure increase after lockup (see 3.1.4) on the downstream (or regulated outlet) side of the valve shall not exceed 10% of the set pressure or 2.5 psi (17.24 kPa), whichever is greater, over a 15-min period (see S1.1.5).

7.1.4 Set Pressure Limits—Unless otherwise specified (see Section 5), the set pressure (see 3.1.7 and Table 10) shall be adjustable within the standard set pressure ranges of 5 to 30, 25 to 60, and 50 to 100 psig (34 to 207, 172 to 414, and 345 to 689 kPa). If required, more than one spring may be used to accomplish this.

7.1.5 Accuracy of Regulation—Unless otherwise specified (see Section 5), the valve shall provide an accuracy of regulation (see 3.1.1) per the following:

7.1.5.1 The downstream regulated pressure shall not deviate beyond the values listed in Table 11 when the flow through the valve is increased from zero to the rated capacity.

7.1.5.2 The downstream regulated pressure deviation from the set pressure shall not exceed 0.5 psi (3.45 kPa) for every 10-psi (69-kPa) change in upstream pressure when the upstream pressure is changed at the same flow rate condition.

7.1.6 Capacity Requirements—The minimum required valve flow coefficients ($C_v$) for Type I and II valves, based on the accuracy of regulation specified in 7.1.5, shall be in accordance with Table 2. The minimum required capacity for valves not listed in Table 2 shall be as specified (see Section 5). Valves shall meet the specified capacity required, or any intermediate capacity requirement, while maintaining the regulated pressure within the accuracy limits specified in 7.1.5, without instability and within the vibration requirements of 7.1.7.

7.1.6.1 Capacity Calculation—Calculation of the valve flow ($C_v$) shall be performed from test data (test calculations shall be in accordance with ISA S75.01 and tests in accordance with ISA S75.02) based on the following equations for turbulent flow:

$$C_v = \frac{\text{flow}}{F_p \sqrt{\text{inlet pressure} - \text{minimum delivered flow pressure}}} \quad (1)$$

where:

$F_p$ = piping geometry factor ($F_p = 1.0$ when pipe reducers are not used),

flow = US gal/min of water at 60°F (16°C),

inlet pressure = psig, and

minimum delivered flow pressure = the set pressure, minus allowable pressure deviation permitted, psig.

For example, a 1½-in. (38-mm), Type II, 150-psig (1034-kPa) rated valve with a 150-psig (1034-kPa) inlet water supply pressure and set at 20 psig (138 kPa). The valve delivers 125 gal/min when the minimum regulated downstream pressure drops to 15.5 psig (107 kPa) (that is, 20 psi (138 kPa) less 4.5 psi (31 kPa); note that Table 11 permits a deviation of 4.5 psi (31 kPa) in the regulated pressure).
This satisfies the minimum requirement listed in Table 2 for a 1½-in. (38-mm) valve set at 20 psig (138 kPa). For set pressures between those listed in Table 2, the minimum required $C_v$ shall be obtained by linear interpolation.

7.1.7 Vibration—The valves shall be resistant to Type I environmental vibration in accordance with MIL-STD-167-1. There shall be no resonant frequency from 0 to 33 Hz and no degradation of valve performance when excited in this frequency range (see S1.1.6.3).

7.1.8 Shock—The valve shall retain its set performance capability and suffer no structural damage or permanent deformation after shock testing in accordance with MIL-S-901 and MIL-STD-798 (see S1.1.7 and Section 5).

8. Tests

8.1 Each production valve shall pass the tests outlined below:

8.1.1 Hydrostatic Proof Test—Pressurize the pressure-containing envelope with water to the hydrostatic proof test pressure specified in Table 4. Hold for a minimum of 3 min, depressurize, and pressurize again for 3 additional min to verify conformance with Table 12.

8.1.2 Seat Tightness Test—With water applied to the valve inlet, at pressure equal to the nominal rating of the valve, set the valve lockup at the midpoint of the set pressure range. Measure the downstream pressure increase in a 15-min period in a dead-ended volume not exceeding 100 diameters of downstream piping to verify conformance with Table 12.

9. Marking

9.1 Body Markings—Valve bodies shall be permanently marked to show the following information:

9.1.1 Nominal size,

9.1.2 Pressure rating,

9.1.3 Manufacturer’s name or trademark, and

9.1.4 Flow direction arrow.

9.2 Identification Plates—An identification plate of corrosion-resistant metal shall be attached to the valve and shall list the following:

9.2.1 Manufacturer’s name,

9.2.2 Valve specification code,

9.2.3 Set pressure range, and

9.2.4 Manufacturer’s model or part number.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system which will ensure that all the requirements of this specification are satisfied. This system shall also ensure that all valves will perform in a manner similar to those representative valves subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the quality assurance system that the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

### SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of applicable supplementary requirements shall be agreed upon in writing by the manufacturer and the purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. Initial Qualification Testing

S1.1 Qualification tests shall be conducted at a laboratory satisfactory to the customer and shall consist of the examination and tests outlined in Table 12 and specified in S1.1.1 through S1.1.7. Acceptance criteria shall be as given in Table 12.

S1.1.1 Qualification Test Sample—A sample valve shall be submitted for each type and rating for which qualification approval is desired (for sample size(s) required for shock qualification, see S1.1.7). Qualification approval, based on the examination and test of the sample, will then apply to all sizes of that type and rating covered by this specification (see S1.1.1.1). Detailed engineering drawings of the test valve and assembly drawings of all sizes of that type and rating shall be submitted with the test valve.

S1.1.1.1 Valves of other sizes may be tested upon specific approval by the customer. The use of only one valve size for qualification of a type and rating in accordance with this specification applies only where the test valve is representative of the basic design features of all sizes of the type and rating for which qualification is desired. The customer reserves the right to determine which variations are significant enough to require separate qualification testing.
S1.1.2 Examination Before Testing—Upon receipt of the qualification test sample, the sample valve(s) shall be disassembled and examined visually and dimensionally to determine conformance with the requirements of this specification and complete dimensional conformance to the detailed engineering drawings.

S1.1.2.1 Upon satisfactory completion of the examination specified in S1.1.2, the valve(s) shall be tested as specified in S1.1.3 through S1.1.7.

S1.1.3 Spring Test—The spring from the disassembled sample valve shall be examined visually and dimensionally as follows:

S1.1.3.1 The free spring length shall be measured and an allowance of 0.010 in. (0.254 mm) per inch of free spring length calculated. Fraction of inches of free spring length shall be prorated and added to the calculations for allowance.

S1.1.3.2 The spring shall be fully (solidly) compressed and released.

S1.1.3.3 Ten minutes after release, the spring shall be measured again.

S1.1.3.4 The spring shall not exhibit a set in excess of the allowance calculated in S1.1.3.1.

S1.1.4 Valve Body and Diaphragm Hydrostatic Proof Test—Sample valve body and valve diaphragm hydrostatic tests shall be performed to test the strength and soundness of the pressure-containing envelope. No structural failure, permanent deformation, damage to seating surfaces, or external leakage (except a slight seepage in drip form) from the spring chamber assemblies in Type I valves) shall be acceptable. A visual and dimensional inspection is required after testing (see S1.1.2).

S1.1.4.1 Type I Valve Pressure-Containing Envelope—The hydrostatic test pressure shall be 1.5 times the nominal inlet pressure or design pressure. Table 4 contains a listing of hydrostatic proof pressures. Valve internals shall be removed for the test.

S1.1.4.2 Type II Valve Pressure-Containing Envelope—This test shall be performed as above, except that the body/spring chamber shall be blanked off.

S1.1.4.3 Type I and II Valve Diaphragm Test—The inlet port shall be blanked off and the outlet section of the valve hydrostatically pressurized to create a pressure differential in accordance with 6.1.5. The valves shall be pressurized for 2 min, depressurized, and pressurized again for 2 min. The valve shall be examined at completion in accordance with S1.1.2.

S1.1.5 Lockup Pressure Test (Seat Tightness Test)—The sample valve shall be installed in a test setup that incorporates an accurate means of monitoring pressures at the inlet and outlet (regulated flow) of the valve. The outlet piping shall be arranged so that it shuts off while in a flooded state with no air binding (entrapment) for approximately 100 pipe diameters downstream of the valve. With hydrostatic pressure equal to the rated nominal inlet pressure of the valve applied to the inlet, the valve shall be set to lockup at the midpoint of its pressure range setting. The pressure increase after lockup on the closed downstream (or regulated outlet) side of the valve shall not exceed 10% of the set pressure or 2.5 psi (17 kPa), whichever is greater, over a 15-min period. If the valve fails to meet these requirements, it shall be given a visual and dimensional examination (S1.1.2) to determine the cause.

S1.1.6 Composite Test—The sample valve which has passed the seat tightness test shall be installed in a test setup that incorporates an accurate means of monitoring the flow rate and pressures at the inlet and outlet of the valve. This test setup will facilitate establishment of set pressure limits/accuracy of regulation, capacity, and vibration response.

S1.1.6.1 Set Pressure Limits/Accuracy of Regulation—This test shall be conducted in two parts:

1. Measure the downstream pressure at the minimum and maximum of the set pressure range by applying an inlet pressure equal to the nominal valve rating and varying flow from lockup to full flow to lockup. The droop characteristics (fall off in the downstream pressure) shall be determined by following the procedure in 7.1.6.1. The downstream pressure variation shall not exceed the values listed in Table 11.

2. Adjust the set pressure at the mid range of the set pressure adjustment range of the spring. These set pressures shall be 20 psig (138 kPa) for the 5 to 30 psig (34 to 207 kPa) spring, 40 psig (276 kPa) for the 25 to 60 (172 to 414 kPa) psig spring, and 75 psig (517 kPa) for the 50 to 100 psig (345 to 689 kPa) spring. Keeping the flowrate constant, vary the upstream pressure from (10 + set pressure) psig to (110 + set pressure) psig and measure the downstream pressure. The downstream pressure shall not vary by more than 5 psi (34 kPa).

S1.1.6.2 Capacity Requirements—Following the above, the valve capacity shall be tested. It shall conform to the requirements of 7.1.6.

S1.1.6.3 Vibration—The valve shall be vibration tested with the nominal inlet pressure rating applied to the inlet port and the valve set at approximately the midpoint of the set pressure range. Performance requirements are set forth in 7.1.7.

S1.1.7 Shock Test—Sample size(s) for shock qualification testing shall be in accordance with MIL-STD-798. The valve shall be subjected to the high-impact mechanical shock requirements for Grade A, Class I of MIL-S-901 to determine its resistance to high-impact mechanical shock. The shock test shall be performed with the nominal hydrostatic pressure applied to the inlet port. During impact, an instantaneous, reversible pressure excursion is allowable. After the test, the valve shall be subjected to a visual and dimensional check (S1.1.2) and the tests described in 8.1.1 and 8.1.2. The valve shall meet the requirements of 7.1.8.

S2. Examinations

S2.1 Lot—For the purpose of sampling, all valves of the same type and size offered for delivery at one time shall be considered a lot.

S2.2 Sampling for Visual and Dimensional Examination—A random sample of valves shall be selected from each lot as shown below and shall be examined as specified in S2.3 and S2.4. The failure of any valve in a sample to pass the examination specified in S2.3 and S2.4 shall be cause for rejection of the lot.

S2.3 Visual Examination—A visual examination shall be made of the sample valves selected in accordance with S2.2 to verify conformance to the requirements of this specification.

S2.4 Dimensional Examination—A dimensional examination shall be made on the sample valves selected in accordance with S2.2 to verify conformance with the approved master drawing.

S3. Packaging and Marking Requirements

S3.1 Preservation, Packing, and Marking—Valves shall be individually preserved Level A or commercial, packed Level A, B, C, or commercial as specified (see 5.1.11), and marked in accordance with MIL-V-3.

S3.2 Cushioning, Dunnage, and Wrapping Materials:

S3.2.1 Level A Preservation and Levels A, B, and C Packing—Utilization of all types of loose-fill materials for shipboard use is prohibited.

S3.2.2 Commercial Preservation, and Packing—When loose-fill type materials are used for cushioning, filler, and dunnage, all containers (unit, intermediate, and shipping) shall be marked or labeled with the following information:

“CAUTION
Contents cushioned, etc., with loose-filled material. Not to be taken aboard ship. Remove and discard loose-fill material before shipboard stowage. If required, recushion with polyurethane foam, or transparent flexible cellular material.”

S3.3 Cushioning, filler, dunnage, and wrapping materials selected shall have properties (characteristics) resistant to fire.

S3.4 The valve CID/APL number shall be stamped on the valve name plate.

S4. Quality Assurance

S4.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S4.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S4.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the right of the manufacturer to establish, and from time to time to alter, the form of organization the manufacturer considers appropriate for its work. Individuals performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.

S4.4 Review of the Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S4.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S4.6 Purchase Control—The manufacturer shall ensure that all purchased materials and services conform to specified requirements and that all purchase orders include complete details of the material and services ordered.

S4.7 Material Control—The manufacturer shall have a system for material control that ensures that the material received is properly identified and that any required documentation is present, identified as to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of the material during the manufacturing process by a system that identifies the inspection status of the material throughout all stages of manufacture.

S4.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are conducted under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S4.9 Quality Control Plan—The quality control plan of the manufacturer shall describe the fabrication operations, including examinations and inspections.

S4.10 Welding—The quality control system shall include provisions for ensuring that the welding conforms to specified requirements. Qualifications of the welders shall meet the appropriate standards, and the qualification records shall be made available to the inspection authority if required.

S4.11 Nondestructive Examination—Provision shall be made to use nondestructive examination, as necessary, to ensure that materials and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer or qualified by a recognized national body, and their authorizations and qualification records shall be made available to the inspection authority if required.

S4.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.

S4.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.

S4.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of materials during all stages of manufacture and shall be able to distinguish between inspected and non-inspected material.

S4.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring, and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard, and calibration records shall be maintained.
S4.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S4.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S4.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with either originals or copies of such documents.
Standard Practice for Platforms in Cargo Tanks

This standard is issued under the fixed designation F 1385; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice provides design, construction, and installation criteria for platforms in cargo tanks.

1.2 Where platforms are attached to ladders see Figs. 1-4.

1.3 The values stated in SI (metric) units are to be regarded as the standard. The inch-pound units given in parentheses are for information only.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:
A 36/A 36M Specification for Carbon Structural Steel
2.2 Military Specification:
MIL-G-18015 Grating, Metal, Other than Bar Type (Shipboard Use)
3. Federal Standard:
FED-SPEC-RR-C-271 Chain and Attachments, Welded and Weldless
4. Absolute Standard:
American Bureau of Shipping Rules for Building and Classing Steel Vessels
5. AWS Standard:
AWS D1.1 Structural Welding Code—Steel
6. Other Standards:
SAE-AMS-C-27725 Coatings, Corrosion Preventative, Polyurethane, for Aircraft Integral Fuel Tanks for Use to 250 Degrees F (121 Degrees C)

3. Significance and Use

3.1 This practice establishes the procedure for the construction and installation of platforms to be fabricated and installed by the shipyards within the cargo tanks.

4. Materials and Manufacture

4.1 Materials:

4.1.1 Gratings—1.8-kg (4-lb) expanded metal fabricated in accordance with MIL-G-18015.

4.1.2 Flanged Plate Supports—Fabricated from 10 by 380 mm (approximately 3/8 by 15 in.) with a 75-mm (approximately 3-in.) flange of carbon steel plate in accordance with Specification A 36/A 36M.

4.1.3 Angle Supports—75- by 75- by 10-mm (approximately 3- by 3- by 3/8-in.) structural angles of carbon steel in accordance with Specification A 36/A 36M.

4.1.4 Stanchions—25-mm (approximately 1-in.) diameter carbon steel.

4.2 Manufacture:

4.2.1 Platforms shall be constructed as shown in Figs. 1-4.

4.2.2 The dimensions indicated in Figs. 1-4 are for the commonly used sizes. However, dimensions can be modified to suit other existing structures.

4.2.3 Platforms shall be designed to support static loads of at least 14 kPa (approximately 300 psf).

4.2.4 Platforms shall be locally reinforced where greater loads are contemplated for removal or disassembly of machinery.

4.2.5 All welding shall be in accordance with American Bureau of Shipping Rules for Building and Classing Steel Vessels or AWS D1.1.

4.2.6 Tolerances shall be ±6 mm (approximately 1/4 in.).

5. Dimensions

5.1 Openings in railings serving ladders to lower levels shall not be more than 690 mm (approximately 27 in.) wide.
5.2 Safety chains with snap hooks shall be provided to close such openings at heights of 530 and 1060 mm (approximately 21 and 42 in.) above the walking surface. Chain shall be welded and shall be in accordance with FED-SPEC-RR-C-271.

6. Workmanship, Finish, and Appearance

6.1 Platforms shall be free of all sharp edges, burrs, projections, weld splatter, and other defects that might be injurious to personnel or equipment, or both.

6.2 For cargo tanks carrying cargo other than fuel oils, coat platforms with one coat 3.0-MIL dry film thickness inorganic zinc silicate following surface preparation in accordance with the Steel Structure Painting Council Specifications or the manufacturer’s paint instructions.

6.3 For spaces carrying fuel oil cargo, one coat of 3.0-MIL dry film thickness of corrosion preventive coating shall be applied to the platforms in accordance with SAE-AMS-C-27725.

6.4 Grating sections are to be tested in accordance with MIL-G-18015 or as follows: Support a section of grating on

7 Available from Steel Structures Painting Council (SSPC), 40 24th St., 6th Floor, Pittsburgh, PA 15222–4656.
two supports each 25 mm (approximately 1 in.) wide and 915 mm (approximately 36 in.) apart. The test load is to be three times the design load. The test load is to be suspended from a bar 610 by 50 mm (approximately 24 by 2 in.) applied across the grating midway between the supports.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.
Standard Guide for Construction of Sounding Tube and Striker Plate for Tank Sounding

This standard is issued under the fixed designation F 1386; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers design and construction criteria for striker plates and sounding tubes, excluding deck penetrations and caps, for use with sounding rods or tapes in freshwater, saltwater, and oil tanks.

1.2 The values stated in inch-pound units are to be regarded as the standard. The SI units given in parentheses are for information only.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:

A 36/A 36M Specification for Carbon Structural Steel
A 53/A 53M Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless
F 722 Specification for Welded Joints for Shipboard Piping Systems
F 1155 Practice for Selection and Application of Piping System Materials

2.2 ANSI Standards:

B16.5 Pipe Flanges and Flange Fittings
B16.9 Factory Made Wrought Steel Butt Welding Fittings
B16.11 Forged Steel, Socket Welding and Threaded Fittings
B16.28 Wrought Steel, Butt Welding, Short Radius Elbows and Return
B31.1 Power Piping

2.3 ABS Standard:

American Bureau of Shipping Rules for Building and Classing Steel Vessels

2.4 AWS Standard:

AWS D1.1 Structural Welding Code

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 external sounding tube—a sounding tube located outside the boundaries of the tank being sounded.

3.1.2 internal sounding tube—a sounding tube located inside the tank being sounded.

3.1.3 sounding—measurement by sounding; a place or part of a body of liquid where a hand sounding line will reach bottom.

4. Classification

4.1 Type I—Internal sounding tube, with separate striker plate.

4.2 Type II—Internal sounding tube, with attached striker plate.

4.3 Type III—Internal sounding tube, with angle striker plate.

4.4 Type IV—External sounding tube.

5. Significance and Use

5.1 Sounding tubes may be fabricated from 1½ NPS or larger. Only when otherwise specified, Schedule 40 components, manufactured from the list of material indicated in Practice F 1155 and Specification A 53/A 53M, Grade S or Grade ERW. In addition, sounding tubes may be fabricated in stainless steel for stainless steel tanks.

5.1.1 Sounding tubes passing through or terminating in fuel tanks, potable water tanks, or clean salt water ballast tanks should be constructed of 70-30 copper nickel, but other suitable material is acceptable.

---

1 Available from American Bureau of Shipping (ABS), ABS Plaza, 16855 Northchase Dr., Houston, TX 77060.

5.2 Striker plates shall be fabricated in accordance with Specification A 36/A 36M.

5.3 The fittings shall be designed in accordance with ANSI B16.5, B16.9, B16.28, or B16.11 as applicable (See Table 21 in Practice F 1155), and the installation shall be in accordance with ANSI B31.1 as modified by Specification F 722. These standards cover the fitting tolerances.

5.4 Some cargo may preclude the use of materials specified in this guide. However, configuration examples are applicable for all applications.

5.5 When a sounding tube is combined with the air escape, either three 1¼-in. (approximately 30-mm) diameter holes approximately 12 in. (305 mm) from the tank top equally spaced or six ½-in. (approximately 15-mm) diameter holes approximately 6 in. (150 mm) from the tank top equally spaced can be used for perforations. See Fig. 2.

5.6 Figs. 1-4 are guidance details.

6. Installation of Sounding Tubes

6.1 Locate sounding tubes as close as possible to the lowest part of the tank.

6.2 Type I, II, and III sounding tubes, excluding oil products, shall be perforated as shown in Fig. 1, Fig. 2, and Fig. 3 respectively, for ventilation.

6.2.1 Type IV sounding tubes are only allowed where the tank cannot be penetrated from the top because of an unavoidable situation, such as a prohibitive location (see Fig. 4).

6.3 Slope and curvature shall be kept to a minimum, and under no circumstances shall the slope be permitted to exceed 45° from the vertical. Radius of curvatures up to a minimum of 10 ft (approximately 3 m) will be permitted where unavoidable.

6.4 Tubes may be provided with flanged take down connections, approximately 18 in. (455 mm) from the tank bottom.
6.4.1 Tubes shall be terminated close enough to tank bottoms to prevent hangup of a sounding device or a thief sampler when they are being withdrawn from a tank.

6.4.2 The inside edges of sounding tube shall be smoothed to prevent hanging up of a sounding device or thief sampler when they are being withdrawn from the tank.

6.5 Tubes shall be adequately supported to withstand both static and dynamic loads.

6.6 Welding shall be in accordance with American Bureau of Shipping Rules for Building and Classing Steel Vessels or AWS D1.1.

SUPPLEMENTARY REQUIREMENTS

S1.1 To ensure the fluid in the sounding tube is representative of the fluid in the tank when taking fuel samples, 1/2-in. (approximately 15-mm) diameter holes, 6 in. (150 mm) apart are drilled in the sounding tubes throughout its length in the tank it serves.
Standard Specification for Performance of Piping and Tubing Mechanically Attached Fittings

1. Scope
1.1 This specification establishes the performance characteristics required for mechanically attached fittings (MAFs) for use in piping and tubing systems. These fittings directly attach to pipe or tube by mechanical deformation of the pipe or tube or fitting, or a combination thereof, creating a seal and a restrained joint. The seal may be created via the mechanical deformation or created independently. Successful completion of the tests described constitutes completion of the technical portion of the qualification process.

1.2 Supplementary requirements are provided for use when additional testing or inspection is desired. These shall apply only when specified in part or whole by the purchaser in the order. Unless otherwise specified, U.S. Navy contracts shall invoke the supplementary requirements in whole.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The following safety hazards caveat applies only to the tests listed in Section 13 and the tests described in the Supplementary Section and the Annex of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.5 Unless specific MAF types are specified, the term “MAF” shall apply to all types described herein.

1.6 The tests specified in Section 13 and described in Annex A1 and Supplementary Requirements are applicable only to ascertain the performance characteristics of MAFs. These tests are not intended for use in the evaluation of non-MAF products.

1.7 A fire performance test is specified in Supplementary Requirement S7. This test provides general guidelines to determine the responsiveness of MAFs when subjected to fire. This test should not be considered for use to evaluate non-MAF products.

3. Terminology

3.1 Definitions:

3.1.1 class, n—a group of MAFs of a particular design with the dimensions proportional to pipe or tube outside diameters, made from the same material grade (or combination of grades), for the same rated pressure, or for a rated pressure inversely proportional to the diameter.

3.1.1.1 Discussion—Class designation for MAF is assigned based upon the rated pressure used to test the MAF design.

3.1.2 failure, n—any leakage or joint separation unless otherwise determined to be due to a tubing/pipe or fitting defect.

3.1.3 fitting, n—connecting device used to join multiple pipes or tubes or other MAFs together to create a working system.

3.1.3.1 Discussion—Shapes such as couplings, unions, elbows, tees, crosses, plugs, adapters, reducers, flanges, and special shapes are used as needed to fulfill MAF system design specifications.

3.1.4 joint, n—interface between pipe or tube and MAFs where the seal is maintained or mechanical holding strength is applied or maintained within the overall MAF design.

3.1.5 leakage, n—the escape of fluid or gas from any point of the MAF, including the MAF joint interface, sufficient to drop or flow from the point of formation or gas bubbles rising to the surface after the first minute of submersion.

3.1.6 mechanically attached fitting (MAF), n—a fitting that is directly attached to pipe or tube by mechanical deformation of the pipe/tube or fitting, or both, creating a seal and a restrained joint. The seal may be created via the mechanical deformation or created independently.

3.1.7 penalty run, n—a penalty run is performed with penalty run MAF specimens when the original MAF test specimen leaks or separates during testing as a result of any cause that is not related to the design of the MAF being qualified.

3.1.8 penalty run MAF specimens, n—additional specimen(s) that are tested in the place of the original specimen(s) (see 3.1.7).

3.1.8.1 Discussion—These additional MAF specimen(s) are assembled using the same methods along with additional MAFs of the same type, grade, class, and configuration and additional pipe or tube with the same wall thickness and material conditions as the original test specimen.

3.1.9 permanent MAF, n—a fitting whose joint(s) attach directly to the pipe or tube to join two or more pipes or tubes or other MAFs in a combination of pipes or tubes and components. In either case, the permanent MAFs cannot be disassembled and reused after initial assembly.

3.1.10 pipe, n—hollow round product conforming to the dimensional requirements for nominal pipe size (NPS) as tabulated in ANSI B36.10, Table 2.

3.1.11 rated pressure, n—the manufacturer’s recommended in-service pressure assigned to the MAF (see 3.1.15).

3.1.12 separable MAF, n—a fitting whose joint(s) attach directly to the pipe or tube to join two or more pipes or tubes or other MAFs in a combination of pipes or tubes and components. Once assembled, the separable MAFs can be disassembled and reassembled a multiple number of times.

3.1.12.1 Discussion—Some subcomponents of separable MAFs may become permanently attached to the pipe or tube without affecting the function of the joint.

3.1.13 specimen, n—a prepared assembly consisting of a MAF assembled onto a preselected pipe or tube. The specimen is placed into a controlled environment and tested to determine if the MAF assembly meets the requirements specified in the test being performed.

3.1.14 test pressure, n—a selected pressure used during testing, which is based upon the rated pressure (see 3.1.13) of the MAF or pipe or tube, whichever is lower, times the factor specified for each test (that is, 1.25, 1.50, 2.00, 4.00, and so forth).

3.1.15 tube, n—hollow round product which is usually specified with respect to outside diameter and wall thickness.

4. Classification

4.1 MAFs are classified into the following design types:

NOTE 1—Each MAF type may consist of more than one material and class.

4.1.1 Type I: Radially Swaged MAF (Permanent)—A portion of the MAF diameter is reduced mechanically by means of an installation tool through radial compression to provide an intimate joint. The properly installed MAF has a circumferential deformation of predetermined dimensions.

4.1.2 Type II: Flared MAF (Separable)—An assembly that consists of a body, nut, and sleeve. The MAF is designed to mate with a tube or other component which has been flared or

14 Available from Society of Automotive Engineers, 400 Commonwealth Dr., Warrendale, PA 15096.
15 Available from American Society of Mechanical Engineers, 345 E. 47th St., New York, NY 10017.
machined to a specific angle. The flared tube end is positioned onto the MAF body cone or seat. The nut is then tightened to the body thread, thus providing a tube-to-MAF seal through mechanical retention.

4.1.3 Type III: Flareless (Bite-Type) MAF (Separable)—An assembly having a ferrule, nut, and body. The ferrule penetrates the outside of the tubing, thus providing a pressure seal and holding mechanism.

4.1.4 Type IV: Grip-Type MAF (Separable)—An assembly having one or two ferrules that are compressed into the surface of the tube. In the case of the two-ferrule MAF, the forward ferrule provides the primary seal through radial compression around the outer diameter of the tube. The rear ferrule acts as the primary mechanical holding device. In the case of the single-ferrule design, the ferrule is used to seal and act as the primary mechanical holding device.

4.1.5 Type V: Shape Memory Alloy (SMA) MAF (Permanent)—Mechanically attached fittings that use SMA to provide the mechanical force required to produce a metal-to-metal seal between the pipe or tube and the MAF. The metal-to-metal seal that is formed is a “live crimp” since the pipe or tube and the SMA are in a state of dynamic equilibrium. The SMA maintains a permanent inward radial force on the pipe or tube at all times. The MAF body itself may be manufactured from a nonshape memory metal and used in conjunction with a driver made from SMA.

4.1.6 Type VI: Axially Swaged MAF (Permanent)—Mechanically attached fittings that have machined swaging rings telescopically “press fit” from the extremities toward the center of the MAF body. An installation tool advances the swaging rings axially over the MAF body into a seated and locked position. The swage rings compress the MAF body onto the pipe or tube forming a metal-to-metal seal. The seal is permanently maintained by the force radially exerted by the swaging rings onto the sealing interface.

4.2 The MAFs shall be made from one or more of the following material grades:

4.2.1 Grade A—Carbon steel.
4.2.2 Grade B—Stainless steel.
4.2.3 Grade C—Nickel-copper.
4.2.4 Grade D—Copper-nickel.
4.2.5 Grade E—Brass.
4.2.6 Grade F—Nickel titanium.

4.3 The MAF rated pressure may be one of the following classes:

Note 3—The rated pressure may differ within the size range of a MAF being qualified (see 3.1.1).

4.3.1 Class 1—1.38 MPa (200 psi) maximum.
4.3.2 Class 2—2.76 MPa (400 psi) maximum.
4.3.3 Class 3—4.83 MPa (700 psi) maximum.
4.3.4 Class 4—6.90 MPa (1000 psi) maximum.
4.3.5 Class 5—10.34 MPa (1500 psi) maximum.
4.3.6 Class 6—13.79 MPa (2000 psi) maximum.
4.3.7 Class 7—20.69 MPa (3000 psi) maximum.
4.3.8 Class 8—25.86 MPa (3750 psi) maximum.
4.3.9 Class 9—34.48 MPa (5000 psi) maximum.
4.3.10 Class 10—41.37 MPa (6000 psi) maximum.

5. Ordering Information

5.1 Orders for MAFs under this specification shall include the following:
5.1.1 ASTM designation, title, number, and year of issue;
5.1.2 Quantity of fittings (MAF);
5.1.3 Size, nominal pipe size (NPS), or outer diameter (OD);
5.1.4 Type (I, II, III, IV, V, or VI);
5.1.5 Material grade (see 4.2, 6.1, or Table 1),
5.1.6 Class (see 3.1.1 and 4.3);
5.1.7 MAF shape (that is, straight, elbow, cross, union, coupling, and so forth) (see 3.1.3);
5.1.8 Supplementary requirements, if any;
5.1.9 Other requirements agreed to between the purchaser and the manufacturer; and
5.1.10 Inspection and acceptance of MAFs as agreed upon between the purchaser and the supplier (see Section 14).

5.2 Optional Ordering Requirements:
5.2.1 Certification (see Section 15);
5.2.2 Special marking requirements (see Section 16 and S1.5).

6. Materials and Manufacture

6.1 MAF Material—The MAF material used may be as specified in Table 1 or may be other materials not specified in Table 1, as agreed to between the manufacturer and the purchaser.

6.1.1 All types may be manufactured from wrought bars, forgings, castings, pipe, or tube.
6.1.2 Flow of Grain—MAFs machined from hot- or cold-drawn bars shall have their longitudinal axis parallel to the longitudinal axis of the bar with at least the center one third of the bar removed during the manufacturing process unless testing shows the center material to be free of injurious defects.

6.2 Material Quality—The material shall be of such quality and purity that the finished product shall have the properties and characteristics to meet the performance requirements of this specification.

6.2.1 The manufacturer is encouraged to use materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. Used or rebuilt products shall not be used.

Note 4—The term “recovered materials” is interpreted as those materials that have been collected or recovered from solid waste and reprocessed to become a source of raw material, as opposed to extra virgin raw materials.

6.3 Seal Materials—Seals used with MAFs shall be as specified in Table 1.
6.4 Surface Applications and Coatings—Surface applications and coatings if applicable, shall be applied and tested in accordance with the requirements specified in Table 2.
6.5 MAF Fabrication—MAFs fabricated from two or more parts may be welded. The use of brazing or soldering is not permitted.
6.5.1 Welding procedure qualification and welding operator performance qualification shall be in accordance with ASME Section IX. Welding process shall be in accordance with MIL-STD-278. Welded MAFs shall be tested in accordance with the requirements as specified in 13.4.3.

6.5.2 The welding procedure qualification test shall duplicate the joint configuration to be used in production.

6.6 Processing Stainless Steel Forgings—Austenitic stainless steel components manufactured by hot forge or other sensitizing processes shall be solution annealed and certified free of intergranular precipitation. Practice A 262 shall be used to evaluate carbide precipitation in stainless steels.

### Performance Requirements

7.1 Testing Requirements—MAFs shall be subjected to the standard performance tests specified in 13.1 and Table 3. The tests are described in the Annexes. Supplementary tests specified in 13.2 and Table S1.1 shall be performed when invoked in the order or contract by the purchaser.

---

| Alternate material in conformance to Specification A 106 (Grade B) may be used. |
| Alternate material in conformance to Specification A 108 may be used. |
| When required by the MAF design, O-rings in accordance with SAE J515 shall be used to connect the MAF end. |
| No O-rings used to connect the MAF end. |
| Alternate material in conformance to Specification A 234/A 234M may be used. |
| Alternate material in conformance to MIL-P-24691/3 may be used. |
| 304, 304L or 316, 316L material may be used. |
| Alternate material in conformance to Specification A 276 may be used. |
| Alternate material in conformance to AMS 5643 may be used. |
| Alternate material in conformance to Specification A 403/A 403M may be used. |
| Alternate material in conformance to QQ-N-281 may be used. |
| Alternate material in conformance to MIL-T-16420 may be used. |
| Alternate material in conformance to Specification B 21 may be used. |
| Alternate material in conformance to Specification B 371 may be used. |
| Alternate material in conformance to QQ-B-626 may be used. |
| In accordance with the manufacturer’s specification. |
7.1.1 These tests shall be repeated any time changes are made in the design, material, or manufacturing process, which in the opinion of the purchaser, may degrade the performance of MAFs.

7.2 Intermixing of MAF Subcomponents—The intermixing by the purchaser of subcomponents of the same design, but of different brands or trade names, is not permitted unless specifically authorized by the manufacturer.

7.2.1 When subcomponents of different brands, trade names, or manufacturers are used, the manufacturer testing the MAF design shall specify this information in the test report.

7.3 Qualification Requirements—MAFs shall be tested using specimens of the same type, grade (or combination of grades), and class. The pipe or tube selected for the technical qualification to this specification shall meet the requirement specified in 7.3.4. Technical qualification of the MAF assembly shall be based upon successful completion of all required testing. Each MAF design is only qualified for use with the pipe or tube material and minimum to maximum wall thickness tested or extended by interpolation (see 7.3.2 and 7.3.3).

7.3.1 Except as required by Annex A11 (Mercurous Nitrate Test), all MAFs tested shall be comprised of an equal number of specimens from the smallest and largest sizes within the size range of the MAF type, grade, and class being tested.

7.3.1.1 Test one or more intermediate sizes if the ratio of the minimum and maximum pipe or tube outside diameter to be tested is equal to or more than five.

7.3.2 Through reasonable interpolations between the MAF sizes tested, all other sizes of MAFs within the same type, grade (or combination of grades), and class, will be considered acceptable if the MAF specimens pass all of the testing requirements specified by the purchaser. Extrapolation is not acceptable.

7.3.3 Acceptance of tees, elbows, and other shapes within the same class, may be accomplished by parametric analysis (see 7.3.3.1), as agreed to between the manufacturer and the purchaser based on the acceptance of couplings.

7.3.3.1 If tees, elbows, and other shapes are made from a different raw material form than the coupling (for example, tees and elbows manufactured from castings versus couplings manufactured from solid bar or round tube), this alternate material form shall undergo the same test regimen as the MAF manufactured from solid bar or round tube, this alternate material form shall undergo the same test regimen as the MAF manufactured from solid bar or round tube.

7.3.4 Recommended pipe or tube for use with MAFs may be qualified throughout its wall thickness range, when pipe or tube of a minimum and maximum wall thickness are used within the test specimens being qualified.

7.3.5 The MAFs may incorporate non-MAF features that are part of a MAF configuration shall meet the current issue of existing military and commercial documents (as applicable). Qualification of the non-MAF features are not within the scope of this specification.

7.4 Test Report—Upon completion of testing, a test report shall be written and maintained on file during the life cycle of
the design. A copy of this report shall be made available upon request from the purchasing activity.

7.4.1 A failure during testing shall be analyzed and the failure analysis (see 11.3.1 and 11.3.2) and corrective action shall be included in the test report.

7.4.2 A retest as specified in Section 11 may be allowed when failure of the original assembly occurs during testing. When retesting is permitted, the failure analysis and corrective action shall be included in the test report as specified in 7.4.1.

7.5 Test Equipment and Inspection Facilities—The manufacturer shall ensure that test equipment and inspection facilities of sufficient accuracy, quality, and quantity are established and maintained to permit the performance of required inspections.

7.5.1 Calibration System Requirements—The manufacturer shall maintain a calibration system for all measuring and test equipment (M & TE) in accordance with MIL-STD-45662 with traceability to the National Institute of Standards and Technology (NIST).

7.5.1.1 Accuracy of the M & TE used to measure allowable variables during testing shall be within one third of the tolerances permitted (see 7.6).

7.6 Test Conditions—Unless otherwise specified in the test, the following tolerances shall be used to control conditions of the tests specified in the Annex:

7.6.1 Ambient Conditions—When ambient is specified, standard ambient conditions shall be maintained at 25 ± 10°C (77 ± 18°F).

7.6.2 Pressure—Unless otherwise specified, the tolerance for the internal pressure applied to the test specimen during testing shall be maintained at ±5%.

7.6.3 Test Fluids—Unless otherwise specified, the test fluids used in the testing of MAF shall include those fluids specified within the test. Water and other fluids such as SAE Grade 10W, MIL-H-5606, MIL-L-7808, or MIL-H-83282 may be used without affecting the validity of the test.

7.6.4 Temperature—Unless otherwise specified, the allowable tolerance for temperature applied to the test specimen during testing shall be ±5°C (±10°F).

7.7 Pass or Fail Criteria—Pass or fail criteria for each test shall be based upon meeting or exceeding the performance requirements specified in each test.

8. Dimensions

8.1 MAF Dimensions:

8.1.1 Type I MAF dimensions shall be as specified by the manufacturer.

8.1.2 Types II and III MAF dimensions shall be as specified in MIL-F-18866 or SAE J514 or as agreed to between the manufacturer and the purchaser.

8.1.3 Type IV MAF dimensions shall be as specified by the manufacturer.

8.1.4 Type V MAF dimensions shall be as specified by the manufacturer.

8.1.5 Type VI MAF dimensions shall be as specified by the manufacturer.

9. Workmanship, Finish, and Appearance

9.1 Machined Surfaces—Machined surfaces shall be free from burrs, cracks, laps, or seams which would affect the suitability for the intended service.

9.1.1 All machined surfaces shall be 3.2-µm roughness, average (Rₐ) (125-µin. Rₐ) as specified in ANSI B46.1 or duplicate of that qualified.

9.1.1.1 External surfaces that do not affect the overall function of MAFs shall be excluded from the requirement specified in 9.1.1.

9.2 Unmachined Surfaces—Unmachined surfaces, such as forging or casting surfaces and bar stock flats, shall be free from scale, blisters, fins, folds, seams, laps, segregations, or cracks which may be injurious to personnel or equipment or affect MAF performance.

10. Sampling for Testing

10.1 Inspection Sampling of Raw Material—Except when specified herein, the number of samples required for inspection of raw materials for conformance of products during manufacturing and processing shall be in accordance with established quality assurance procedures maintained by the manufacturer and approved by the purchaser.

10.2 In-Process Inspection Sampling of MAFs—Inspection sampling plans of MAFs being manufactured or processed shall be mutually agreed upon between the manufacturer and the purchaser. MIL-STD-105 shall be used when specified in the purchase order or contract. Level of inspection and acceptable quality level (AQL) shall be in accordance with the manufacturer’s quality assurance procedures.

10.3 Lot Acceptance—Lot acceptance sampling plans shall be mutually agreed upon between the manufacturer and the purchaser. MIL-STD-105 shall be used when specified in the purchase order or contract.

10.4 Sampling for Inspection of Type III Ferrules—A random sample of ferrules shall be selected from each lot in accordance with MIL-STD-105, Special Inspection Level S-2, AQL of 2.5, and tested in accordance with 13.4.1. Other inspection or sampling plans may be used upon mutual agreement between the manufacturer and the purchaser.

10.4.1 A minimum of five ferrules shall be randomly selected from each lot and subjected to the testing specified in 13.4.2.

10.5 Sampling for Inspection of Fabricated MAFs—A minimum of four samples shall be selected at random from each lot of welded products and subjected to the tests specified in 13.4.3.

11. Number of Tests and Retests

11.1 Number of Test Specimens—The tests used to qualify MAFs and the number of specimens required for each test shall be as specified in Table 3.

11.2 Replacement of Test Specimens—When untested specimens are rejected as a result of overtightening, inferior workmanship or materials, or assembly, the specimens shall be dispositioned in accordance with the manufacturer’s quality assurance procedures.
11.2.1 The original unique numbers assigned in accordance with 12.3.1 shall be recorded in the test report along with the reason for rejection.

11.2.1.1 New test specimens with MAFs of the same type, grade, and class, and pipe or tube of the same outside diameter and wall thickness shall be prepared in accordance with Section 12.

11.3 Penalty Runs—In the event of a test failure, the manufacturer shall proceed with one of the following options:

11.3.1 If the failure is determined to be design related, the manufacturer shall redesign the MAF and start all tests from the beginning. The requirements in 11.3.2 shall not apply to redesigned MAF.

11.3.2 If the failure is determined to be unrelated to the design, the test specimen shall be rerun. A replacement test specimen shall be prepared in accordance with the requirements in 11.2 and Section 12.

11.3.3 If the failure cannot be determined to be either design related or not design related, the manufacturer shall test three additional penalty specimens. The requirements specified in 11.3.2 shall apply.

11.4 Penalty Run Specimen Preparation—Penalty run specimens shall be prepared when MAF has failed any of the tests specified in the Annexes.

11.4.1 The MAF used for penalty runs shall be of the same type, grade, and class as the failed MAF being replaced.

11.4.2 The pipe or tube used in penalty runs shall be of the same material (including form and condition), outer diameter, and wall thicknesses as the pipe or tube being replaced.

11.4.3 Preparation of the penalty run specimens shall be in accordance with Section 12.

11.4.4 Penalty run specimens shall be identified in accordance with 12.3 and 11.4.5.

11.4.5 In addition to the part number and test specimen number, a designator shall be placed after the test specimen number which would allow the specimen to be identified as a penalty run specimen. The method used to identify penalty run specimens shall be at the manufacturer’s option.

12. Specimen Preparation

12.1 Specimen preparation and installation of MAFs on appropriate testing apparatus shall be in accordance with the manufacturer’s recommended procedures.

12.1.1 Permanent MAFs shall be assembled at the minimum allowable insertion depth permitted by the manufacturer’s recommended procedure.

12.1.2 Separable MAFs shall be assembled using the minimum value (that is, torque, nut rotation, and so forth) permitted by the manufacturer’s recommended procedure.

12.2 Assembly of Specimens—MAFs qualified under the requirements of this specification shall be tested and qualified as a completed assembly. The acceptance of similar, but different, MAF designs shall not permit the intermixing of their subcomponents such as sleeves, nuts, and ferrules.

12.2.1 Test specimens used in testing shall be assembled using a MAF of a single type, grade (or combination of grades), and pipe or tube material.

12.2.2 The wall thickness and outer diameter size of the pipe or tube shall be selected in accordance with the MAF sizes (see 7.3.4) being qualified.

12.2.3 The test specimens shall be assembled using the specimen geometry specified in Fig. 1.

12.3 Identification of Test Specimens—Each test specimen shall be identified with a unique number to provide traceability back to the test records.

12.3.1 Identification of test specimens shall be permanent. In those cases in which size or design does not permit permanent markings, tagging or bagging may be used.

12.3.2 When, as a result of testing, a test specimen is sectioned into two or more pieces, the identification method shall be as specified in 12.3.1.

13. Test Methods

13.1 Standard Qualification Tests—All tests used to qualify MAFs shall be as specified in the Annexes. The following primary tests are described:

</tbody>
</table>

13.3 Certification of Test Results—If certified test results are required, a certification shall be provided to the purchaser as specified in the contract or purchase order.

13.4 In-Process Inspection Tests—The following tests shall be performed by the manufacturer in accordance with in-house practices and when specified in the contract or purchase order:

13.4.1 Metallographically prepare, microexamine, and test for hardness and microstructural conformance to the manufacturer’s appropriate specification a random sample of Type III ferrules, as specified in 10.4.1. An appropriate specification is defined as the documented procedures that the manufacturer uses on a continuing basis to produce ferrules. Such ferrules shall be of the same quality as those used in the assemblies that were previously tested and found to satisfy the performance requirements of this specification.

13.4.2 Randomly select a minimum of five Type III ferrules from each lot as specified in 10.5 and test for cut bite quality.

13.4.2.1 Preset the Type III ferrules onto tubing as specified in 13.4.2.2. After disassembly, drive back each ferrule to expose the ring cut for examination. The cut bite shall completely encircle the periphery of the tube. The cut bite shall be clean, smooth, and uniform. A jagged irregular cut bite is unacceptable. There shall be no longitudinal or circumferential cracks on the ferrule before driving it back.

13.4.2.2 Use Type 304 tubing in accordance with Specifications A 213/A 213M, A 249/A 249M, or A 269 for testing corrosion-resistant steel MAFs. Use SAE 1010 tubing to test carbon steel MAFs. The tubing materials as specified will assure consistent results of testing. Preset Type III ferrules onto the tubing in accordance with the manufacturer’s recommended procedures using either a presetting machine, presetting tool, or the MAF.

13.4.2.3 When the Type III ferrules are manufactured from materials other than those specified in 13.4.2.2, conduct the test using tubing material as recommended by the manufacturer.

13.4.3 Fracture test a minimum of four MAFs selected at random from each lot of welded MAFs as specified in 13.4.3.1 and then either crush test in accordance with 13.4.3.2 or macroexamine in accordance with 13.4.3.3.

13.4.3.1 Test two MAFs. Cut each MAF into two or more sections. Cut the sections so that the weld is perpendicular to the longitudinal axis of the section. The total width of the sections taken from each MAF shall be equal to or exceed one fourth of the circumference of the MAF. Remove all weld flashing. Load each section laterally in such a way that the root of the weld is in tension. Bend the section until it fractures or is bent 90°. If the specimen fractures, the fractured surface shall show no evidence of preexisting cracks or incomplete fusion, and the sum of the lengths of inclusions and porosity visible on the fractured surface shall not exceed 10 % of the total area. Cracking or tearing of the parent material is acceptable.

13.4.3.2 Two MAFs shall be tested. Remove all weld flashing. Position each MAF between two parallel plates in a manual or hydraulic press, or between the jaws of a multiple-jaw hydraulic press. The weld shall be located 3.2 mm (½ in.) from the face of the plates or jaws. Flatten the MAF against itself between the parallel plates or crush the MAF to within 50 % of its original diameter between the multiple jaws. There shall be no indication of cracking or tearing in the weld joints. Cracking or tearing of parent material is acceptable.

13.4.3.3 Test two MAFs. Take a cross section of the weld from each MAF. Smooth and etch one face of each cross section to give a clear definition of the weld metal and heat-affected zone. When examined, the weld and the heat-affected zone shall show complete fusion and freedom from cracks.

14. Inspection

14.1 Terms of Inspection—Unless otherwise specified in the contract or purchase order, the manufacturer is responsible for the performance of all inspection requirements (examination and tests) specified herein.

14.2 Raw Material Inspection—Each lot of raw material used to produce MAFs in accordance with this specification shall be inspected for conformance to the applicable material specification. A lot of raw material shall consist of bars, pipe, tube, forgings, or castings of the same heat, produced at essentially the same time and submitted for inspection at the same time.

14.3 Quality Conformance Inspection—MAFs shall be visually and dimensionally examined to verify compliance with the appropriate drawings. Quality conformance inspection shall be performed on each lot of MAFs produced under this specification.

14.3.1 The inspection lot of MAFs shall include MAFs of the same size and shape manufactured under essentially the same conditions from the same lot of material and submitted for inspection at one time.

14.4 Process Control Inspection—MAFs shall be inspected throughout the entire manufacturing and processing cycle. Methods of inspection shall be in compliance with the manufacturer’s quality assurance procedures.

14.5 Inspection Records—Inspection records shall be maintained by the manufacturer. The length of time on file shall be in accordance with the manufacturer’s quality assurance procedures.

14.6 Performance Testing Records—The manufacturer shall maintain a record of all performance tests throughout the life of the MAF design.

14.6.1 The original test specimens, as well as replacement or penalty run specimens, used in performance testing to meet qualification shall be maintained by the manufacturer for a minimum of two years.
14.6.2 Inspection records relating to the performance tests shall be maintained in accordance with 14.5.

15. Certification

15.1 Certification of Testing or Inspection—When requested by the purchaser, the manufacturer shall supply written certifications that the MAF has been tested and qualified in accordance with this specification.

15.2 Certification of Raw Material—A certificate of compliance or mill certificate shall be obtained from the material supplier. This certificate shall state that all applicable requirements of the raw material are met. As a minimum, the material specification shall specify the chemical and mechanical requirements of the material.

16. Product Marking

16.1 Product Marking—Each MAF shall be marked with the manufacturer’s name or trademark, size, and material (material marking is not required for Type V MAF). When shape or size does not permit inclusion of all required markings, the information may be omitted in the reverse order presented.

16.1.1 When MAFs are comprised of multiple components that are assembled, the marking methods used to identify the assembly (and each of its components) shall be as agreed to between the manufacturer and the purchaser.

16.2 Additional Markings—When specified in the contract or purchaser order, additional markings other than those specified shall be applied.

17. Keywords

17.1 axially swaged; bite-type; elastic strain preload (esp); fittings; flared; flareless; grip type; mechanically attached fittings (MAFs); piping; radially swaged; shape memory alloy (SMA); tubing

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified in part or whole by the purchaser in the contract or purchase order.

S1. GENERAL REQUIREMENTS

S1.1 Scope

S1.1.1 This section covers the general requirements that, unless otherwise specified, apply to the Annex or this section whenever invoked individually or collectively by the purchaser of MAFs in the contract or purchase order. The testing requirements specified herein are applicable to all the tests described in Sections S2 through S8 (see Table S1.1). The requirements covered herein are outlined as follows:

S1.3 Testing Requirements
S1.4 Quality Assurance Requirements
S1.5 Product Marking Requirements

S1.1.2 Cadmium plating shall not be used on MAFs intended for use on U.S. Navy vessels.

S1.1.3 This section is applicable to MAFs that are designed for the following pipe or tube sizes:

S1.1.3.1 This supplementary section is applicable to MAFs suitable for pipe outside diameters for NPS 3.2 mm ( 1⁄8 in.) through 63.5 mm (2 1⁄2 in.).

S1.1.3.2 This supplementary section is applicable to MAFs suitable for tube outside diameters from 6.4 mm (0.250 in.) to 73.0 mm (2.875 in.).

S1.1.3.3 Other pipe or tube sizes, with supporting data, may be submitted to the purchaser for evaluation and approval.

S1.1.4 The following supplementary tests listed herein are as follows:

<table>

S1.1.6 Unless otherwise specified, the requirements specified in the main body and Annex A1 and Annex A2 of this specification shall apply.

S1.1.6.1 In the event of a conflict between this supplement and the requirements specified in the main body of this specification and Annex A1 and Annex A2, or both, the requirements specified herein shall take precedence, unless otherwise invoked in the contract or purchase order by the purchaser.

S1.1.7 Before beginning performance testing, the manufacturer shall obtain approval from the purchaser of the test plan to be used. The plan shall include the following information:

S1.1.7.1 A matrix showing the MAF grade(s) (or different combination(s) of grades) (see 4.2) and MAF class(es) (see 4.3) to be qualified,

S1.1.7.2 MAF sizes selected to qualify every size within its range (see S1.1.3),

S1.1.7.3 Compatible pipe or tube materials to be in assembly with the MAFs to be tested (see Table S1.2),

S1.1.7.4 Pipe or tube wall thicknesses and sizes selected to qualify the pipe or tube throughout its range (see S7.3.5),

S1.1.7.5 The manufacturer’s recommended procedure covering the assembly of the MAFs onto pipe or tube (see 12.1), and

S1.1.7.6 Test fluids used for each test (see S7.6.3).

S1.1.8 After verification, the purchaser shall approve the matrix or specify any additional tests required for each MAF family for the manufacturer to include in the program.

S1.2 Significance and Use

S1.2.1 The significance of this section allows the purchaser of MAFs to invoke those general, testing, or quality assurance requirements individually or collectively to meet their existing requirements. The purchaser may use this section as a guide to make out an agreement with the manufacturer to fulfill their requirements for MAFs.

S1.3 Testing Requirements

S1.3.1 MAF test specimens shall be selected for qualification in accordance with the requirements specified herein and in 7.3.

S1.3.1.1 Each and every pipe or tube size (both outside diameter and wall thickness) and each and every material combination of both pipe or tube (including annealed and drawn conditions) and MAFs may be qualified in accordance with this specification. If the manufacturer can demonstrate by parametric or test data that some tests are not necessary, the purchaser may exempt the manufacturer from the test requirement on a case-by-case basis.

S1.3.2 The test MAFs shall be of the same base material as the pipe or tube. Other combinations of materials, approved for use by the purchaser, must be shown to be galvanically compatible, or in accordance with MIL-STD-889.

S1.3.2.1 MAFs shall be shown to meet the requirements of this specification over the full range of pipe or tube tolerances (see S1.3.3.1) either experimentally or by parametric.

S1.3.3 Pipe or tube materials used with MAFs shall conform to the specifications listed in Table S1.1.

S1.3.3.1 Pipe or tube tolerances shall be in accordance with the requirements specified in Table S1.2.

S1.3.3.2 In no case shall the pipe or tube used for testing be machined or otherwise changed from its original mechanical or chemical properties unless otherwise specified in the manufacturer’s installation instructions.

S1.3.3.3 The cut pipe or tube ends may be deburred, but not tapered or otherwise reduced, below the minimum wall thickness.

S1.3.4 Strain gages (as required) shall be placed at a distance not to exceed 4.6 mm (0.18 in.) from the end(s) of the MAF pipe or tube joint (see Fig. 1).

S1.3.5 The test specimens shall be marked using the same methods which will be applied to MAFs sold subsequent to qualification.

S1.3.5.1 All test specimens shall be identified in accordance with the requirements specified in 12.3.

S1.3.6 A test specimen shall consist of one or several pipe(s) or tube(s) joined to MAFs.

S1.3.6.1 MAFs installed on the test apparatus shall be in accordance with the manufacturer’s recommended procedures as approved by the purchaser. No other means of joining the test connector to the pipe shall be permitted.

S1.3.6.2 Unless otherwise specified in the individual test, (see S7) the specimen geometry (Fig. 1) shall be no less than five pipe or tube diameters (outside diameter) long on the end of the MAFs being tested.

S1.3.6.3 After approval of the test plan (see S1.1.7), the test specimens shall be assembled in accordance with the requirements specified in 12.2.

S1.3.7 The minimum amount of specimens required for each supplementary test shall be as specified in Table S1.1 (see S1.3.8). A family of MAFs shall consist of a manufacturer’s single combination of: pressure rating (class), design (type), and material (grade) including form and condition. A family requires tests as follows:
S1.3.7.1 Test each MAF shape. Shapes may be test exempted only if it can be shown to the purchaser’s satisfaction that they are equivalent to those shapes tested.

S1.3.7.2 Test the range of MAF sizes, including the smallest and largest. Test one or more intermediate sizes if the ratio of the minimum to the maximum pipe or tube outside diameter to be tested is equal to or more than ten.

S1.3.7.3 Any nonproportional MAF sizes shall be tested unless they can be shown parametrically to be equivalent to the sizes tested.

S1.3.7.4 Test each pipe or tube material for all material conditions of intended use (that is, annealed and drawn).

S1.3.7.5 For each pipe or tube size being tested, test the minimum and maximum nominal wall thickness of pipe or tube materials selected from Table S1.2.

S1.3.8 A minimum of 60 specimens shall be prepared to cover the unique combinations of a MAF family (see S1.3.7). Each primary test shall have a minimum of five specimens representing all of the unique combinations of a MAF family. When the total amount of specimens (including Annex) is below 60, additional specimens shall be added to attain the minimum of 60 total specimens for all tests (see S1.3.8.5).

S1.3.8.1 The total number of test assemblies must each pass their designated tests successfully to meet the requirements of this performance specification.

S1.3.8.2 The proposed test plan covering unique combinations of test assemblies used in qualification testing shall be submitted to the purchaser for approval (see S1.1.7).

S1.3.8.3 The pneumatic test (see Annex A3), the hydrostatic test (see Annex A4), and the hydrostatic burst test (see Annex A8) (when performed separately or in combination before or after another primary test) are not to be used as a part of the total specimens used for testing because they are connected with the pass and fail criteria of the primary test. In all instances, they are considered to be a part of the primary test and not a separate mechanical test for this calculation.

S1.3.8.4 Also, comparison tests of pipe or tube without MAFs do not count as part of these totals.

S1.3.8.5 Specimens may be reused for other primary tests as long as all of the requirements herein are complied with for each test (see S1.1.7).

S1.3.9 In the event of a test failure, the manufacturer shall proceed in accordance with 11.3.

S1.3.10 At the option of the purchaser, the test laboratory shall cut open or otherwise prepare specimens for detailed examination following any failure.

S1.3.11 Unless otherwise specified within the test, the conditions for testing shall be as specified in 7.6 and as follows:

S1.3.11.1 Unless otherwise specified by the purchaser, the pressures applied during testing shall be calculated based upon the class (rated pressure) assigned by the manufacturer in the test plan (see 4.3). The purchaser may also designate a class not specified in 4.3 to fulfill end-system requirements (see 3.1.1).

S1.3.11.2 The test temperature shall be maintained to within ±5°C (±10°F), unless otherwise specified by the purchaser (see Table S1.3). The test temperature is maintained when the test specimen attains the temperature designated by the test. The temperature shall be stabilized for a period of 1 h or more.

S1.3.12 All testing shall be done at a test laboratory acceptable to the purchaser. The test laboratory shall verify that specimens to be tested are as identified and certify results.

S1.3.12.1 The test laboratory must establish a mutually convenient testing schedule when the purchaser specifies that a witness is to be present during testing.

S1.3.13 Unless otherwise specified, the test report shall contain the following information:

S1.3.13.1 Identification number, a description of each specimen, and the fabrication process.

S1.3.13.2 Description of the test apparatus including instrumentation and their settings during the test.

S1.3.13.3 Photographs of test setup including specimen.

S1.3.13.4 Graphical printout of all data for those tests that record a waveform (if requested by the purchaser).

S1.3.13.5 Leakage rate during testing, if any.

S1.3.13.6 Video tape(s) (fire test only).\(^{c}\)

S1.3.13.7 A record of any unusual observations during testing.

S1.3.13.8 Summary of test results, including but not limited to the following data in tabular form:

1. A description of the specimen shape, pressure rating, material, and method of fabrication,

2. Nominal size, actual pipe outside diameter, actual MAF inside diameter,

3. Pipe material (condition and form), class, and wall thickness,

4. Pressure and temperature, or both, applied during and at the completion of testing,

5. Number of cycles or time at specific atmospheric conditions.

6. Reason for termination of any test,

7. Hydrostatic leakage rate and description, (if any),

8. Summary of pass or fail results, and

9. Calculations (only when requested) to support test data submitted in the test report.

S1.4 Quality Assurance Requirements

S1.4.1 Mill Certification—When specified in the contract or purchase order, a mill certification shall be obtained from the

\(^{a}\)The allowable tolerance for all test temperatures is ±5°C (±10°F).

\(^{b}\)The temperatures given correspond to the category and group system temperatures specified in MIL-STD-777.

\(^{c}\)See test procedure for test temperature requirements.
suppliers of all raw materials used in the manufacturing or fabrication of MAFs. The raw material shall be impounded until required testing or verification, or both, is completed. The types of tests used to verify mechanical, chemical, and physical properties shall be at the option of the manufacturer.

S1.5 Product Marking Requirements
S1.5.1 Unless otherwise specified in the contract or purchase order, the rated pressure of MAFs shall be marked in addition to the markings specified in 16.1.1.

S2. THERMAL CYCLING TEST

S2.1 Scope
S2.1.1 Unless otherwise specified, MAFs shall be subjected to a thermal cycling test. The number of specimens used shall be as specified in Table S1.1.

S2.2 Significance and Use
S2.2.1 This test determines the ability of MAFs to withstand changes in temperature while being pressurized to the rated pressure of the MAFs or pipe or tube, whichever is lower. The test is conducted in high temperature and low temperature. This test is used to duplicate conditions that could occur during in-service use.

S2.3 General Testing Requirements
S2.3.1 The test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.
S2.3.2 An equal number of specimens shall be used for high-temperature thermal cycling (see S2.4.1) and low-temperature thermal cycling (see S2.4.2).
S2.3.3 The tests shall be conducted using the temperatures specified in Table S1.3. The specimen may be tested in an environmental chamber held at test temperature.
S2.3.4 The rated test pressure selected for high- and low-temperature thermal cycling shall be as specified in S1.3.11.1.
S2.3.5 The time for the temperature of the test fluid to change from high or low to ambient conditions (and back again) shall be a maximum of 2 min.
S2.3.6 The test specimens shall be monitored continuously for leakage throughout the test.
S2.3.7 If there is any leakage during the thermal cycling tests or subsequent hydrostatic proof tests, the specimens fail and the test shall be discontinued at that point. If failure occurs, follow the instructions specified in S1.3.9.

S2.4 Procedure
S2.4.1 High-Temperature Thermal Cycling:
S2.4.1.1 Mount the test specimens in an environment suitable for the conditions stated herein.
S2.4.1.2 The duration of the test shall be three cycles as specified in S2.4.1.4 through S2.4.1.6.
S2.4.1.3 Fill the specimen with fluid (see 7.6.3) and pressurize it to the rated pressure specified in S1.3.11.1. Maintain this pressure throughout the test period.
S2.4.1.4 Increase the specimen temperature to the maximum specified in Table S1.3 within 1 h (see S2.3.5).
S2.4.1.5 Stabilize the specimen at the high temperature and rated pressure for a period of 2 h.
S2.4.1.6 At the conclusion of the high-stabilization period, lower the specimen temperature (while maintaining the rated pressure) to ambient conditions within 1 h and stabilize for an additional 2 h (see S2.3.5).
S2.4.1.7 The steps specified in S2.4.1.4 through S2.4.1.6 constitute one cycle. Repeat these steps until three cycles have been completed (see S2.4.1.2).
S2.4.1.8 After the completion of the third cycle, subject the test specimens to a hydrostatic proof test (see Annex A4).
S2.4.1.9 After completing the hydrostatic proof test, and if there was no leakage during the test period, the specimens have passed the high-temperature cycling test.
S2.4.2 Low-Temperature Cycling Test:
S2.4.2.1 Mount the test specimens in an environment suitable for the conditions stated herein.
S2.4.2.2 The duration of the test shall be three cycles as specified in S2.4.2.4 through S2.4.2.6.
S2.4.2.3 Pressurize the specimen with a fluid that will meet the low-temperature requirements for this test. The fluid shall be maintained at the rated pressure as specified in S1.3.11.1 throughout the test period.
S2.4.2.4 Lower the specimen temperature to the temperature specified in Table S1.3 within 1 h (see S2.3.5).
S2.4.2.5 Stabilize the specimen at the low temperature and rated pressure for a period of 2 h.
S2.4.2.6 At the conclusion of the low-stabilization period, raise the specimen temperature (while maintaining the rated pressure) to ambient conditions within 1 h and stabilize for an additional 2 h (see S2.3.6).
S2.4.2.7 The steps specified in S2.4.2.4 through S2.4.2.6 constitute one cycle and shall be repeated until three cycles have been completed (see S2.4.2.2).
S2.4.2.8 After the completion of the third cycle, subject the test specimens to a hydrostatic proof test (see Annex A4).
S2.4.2.9 After completing the hydrostatic proof test, and if there was no leakage during the test period, the specimens have passed the low-temperature cycling test.
S2.5 Precision and Bias

S2.5.1 The precision of the high- and low-temperature cycling test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the high- and low-temperature cycling test when the M & TE used is calibrated properly.

S3. ELEVATED TEMPERATURE SOAK TEST

S3.1 Scope

S3.1.1 Unless otherwise specified, MAFs shall be subjected to an elevated temperature soak test. The number of specimens used shall be as specified in Table S1.1. A minimum of two passed specimens must be submitted for burst test (see Annex A8).

S3.2 Significance and Use

S3.2.1 This test determines the ability of MAFs to withstand a constant temperature level while pressurized to the rated pressure of the MAFs or pipe or tube, whichever is lower. After 100 h, the specimens are cooled to ambient temperature and subjected to further tests. This test is used to duplicate conditions which could occur during in-service use.

S3.3 General Testing Requirements

S3.3.1 The test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.

S3.3.2 The tests shall be conducted using the temperatures specified in Table S1.3 for this test.

S3.3.3 The test pressure selected for the elevated temperature soak test shall be as specified in S1.3.11.1.

S3.3.4 The specimen shall be filled with fluid (see 7.6.3) and pressurized to the rated pressure specified in S1.3.11.1. This pressure shall be maintained throughout the test period.

S3.3.5 If there is any leakage during the elevated temperature soak test, or hydrostatic proof or burst tests, the specimens fail and the test shall be discontinued at that point. If failure occurs, follow the instructions specified in S1.3.9.

S3.4 Procedure

S3.4.1 Maintain the test specimens at the rated pressure and at the temperatures specified in Table S1.3 for the material being tested, for a minimum of 100 h, in an air environment.

S3.4.2 At the completion of 100 h, air-cool the test specimens to ambient temperature.

S3.4.3 After ambient temperature is attained, subject the test specimens to a hydrostatic proof test as specified in Annex A4.

S3.4.4 Upon completion of the hydrostatic proof test, subject a minimum of two test specimens to a hydrostatic burst test in accordance with the requirements specified in Annex A8.

S3.4.5 The specimens successfully pass when there is no visible evidence of leakage during the elevated temperature soak test or during the hydrostatic proof and burst test.

S3.5 Precision and Bias

S3.5.1 The precision of the elevated temperature soak test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the elevated temperature soak test when the M & TE used is properly calibrated.

S4. STRESS-CORROSION TEST

S4.1 Scope

S4.1.1 Unless otherwise specified, MAFs shall be subjected to a stress-corrosion test. The number of specimens used shall be as specified in Table S1.1.

S4.2 Significance and Use

S4.2.1 This test determines the ability of MAFs to withstand the effects of corrosion while being subjected to a bending stress. Upon completion of 50 h, the specimens are examined and then subjected to a hydrostatic proof test (see Annex A4). This test is used to duplicate conditions that could occur during in-service use.

S4.3 General Testing Requirements

S4.3.1 The test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.

S4.3.2 The tests shall be conducted using the temperatures specified in Test Method B 117 for this test.

S4.3.3 The performance test pressure selected for the stress-corrosion test shall be as specified in S1.3.11.1.

S4.3.4 A combined axial stress (bending and internal pressure) applied during the test shall be a minimum of two thirds of the yield strength of the pipe or tube materials specified in Table S1.2. The axial stress as a result of the applied internal pressure shall be calculated using the following formula:

\[ S = \frac{Pd^2}{D^2 - d^2} \]

where
- \( S \) = stress,
- \( P \) = pressure,
- \( D \) = outside diameter, and
- \( d \) = inside diameter.
S4.3.4.1 When other materials are used, cite reference used for yield strength values.
S4.3.5 The apparatus shall be equipped with calibrated gages (see 7.5.1) which permit visual readings of the strain being applied. The apparatus shall be designed to shut down in the event that pressure is lost during the period of the test.
S4.3.6 Calibrated strain gages shall be located on the high stress side of the pipe or tube as shown in the geometries in Fig. 1.
S4.3.7 If there is any leakage during the stress-corrosion test or hydrostatic proof test, the specimens fail and the test shall be discontinued at that point. If failure occurs, follow the instructions specified in S1.3.9.

S4.4 Procedure
S4.4.1 Install the test specimens in a test fixture which can impose a stress level equivalent to two thirds of the yield strength of the pipe or the tube material less the axial stress as a result of the internal pressure (see S4.3.4).
S4.4.2 Apply bending stress to the MAF and pipe or tube interface. Take and record a strain gage reading.
S4.4.3 Pressurize the test specimen to the rated pressure (see S1.3.11.1).
S4.4.4 With the applied stress locked into place, subject the specimen to the standard salt spray test in accordance with Test Method B 117 for 50 h.
S4.4.5 After testing, subject the test specimen to a hydrostatic proof test (see Annex A4).
S4.4.6 Clean and metallurgically examine the test specimen including sectioning of the MAF and pipe or tube throughout the high-stress area. The following conditions shall be checked and shall not have occurred:
S4.4.6.1 Indication of cracking or pitting of the exposed surfaces of MAF and tubing within one diameter of the MAF greater than that exhibited on the remainder of the tubing when visually examined with 10× power magnification.
S4.4.6.2 Leakage or burst at a value less than the specified test pressure (see S4.4.3).
S4.4.6.3 Indications of inter- or trans-granular stress corrosion paths during metallurgical examination of longitudinal and transverse sections of the MAF and pipe or tube junction.
S4.4.7 The specimens successfully pass this test when they complete the stress-corrosion test without showing any of the indications specified in S4.4.6 and successfully complete the hydrostatic proof test requirements specified in Annex A4.

S4.5 Precision and Bias
S4.5.1 The precision of the stress-corrosion test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the stress-corrosion test when the M & TE used is calibrated properly.

S5. TORSION TEST

S5.1 Scope
S5.1.1 Unless otherwise specified, MAFs shall be subjected to a torsion test. The number of specimens used shall be as specified in Table S1.1.

S5.2 Significance and Use
S5.2.1 This test determines the ability of MAFs to withstand displacement of the MAFs and pipe or tube joint through the application of torque. After creating this displacement between the MAF and the pipe or tube, the test assembly is subjected to a hydrostatic proof test in accordance with the requirements specified in Annex A4. This test is used to simulate environmental conditions that could occur during end-service use.

S5.3 General Testing Requirements
S5.3.1 The test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.
S5.3.2 The tests shall be conducted at ambient temperature as specified in Table S1.3 for this test.
S5.3.3 If there is any leakage during the hydrostatic proof test, the specimen fails and the test shall be discontinued at that point. If failure occurs, follow the instructions specified in S1.3.9.

S5.4 Procedure
S5.4.1 Draw a straight line from end to end on the specimen to be tested.
After tightening, the hydrostatic proof test shall be performed from the beginning without any leakage. If leakage occurs during the secondary test, see S5.3.3.

S5.5 Precision and Bias
S5.5.1 The precision of the torsion test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There may be bias in the results of the torsion test if the line drawn has irregular edges or is too thick or is thick and thin, which may make it difficult to measure the amount of actual displacement.

S6. HIGH IMPACT SHOCK TEST

S6.1 Scope
S6.1.1 Unless otherwise specified, MAFs shall be subjected to a high impact shock test. The number of specimens used shall be as specified in Table S1.1. A minimum of two passed specimens shall be used for burst test (see Annex A8).

S6.2 Significance and Use
S6.2.1 This test verifies the ability of MAFs to withstand a series of impacts while being pressurized to the rated pressure of the MAFs or pipe or tube, whichever is lower. This test is used to duplicate in-service conditions that could occur.

S6.3 General Testing Requirements
S6.3.1 The test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.
S6.3.2 The tests shall be conducted using the temperatures specified in Table S1.3 for this test.
S6.3.3 The rated pressure selected for the high-impact shock test shall be as specified in S1.3.11.1.
S6.3.4 If there is any leakage during the high-impact shock test or subsequent hydrostatic proof test, the specimens fail and the test shall be discontinued at that point. If failure occurs, follow the instructions specified in S1.3.9.

S6.4 Procedure
S6.4.1 Fill each test specimen with fluid in accordance with 7.6.3 before installation onto the shock test fixture.
S6.4.2 Pressurize the test specimens to the rated pressure of the MAF or pipe or tube, whichever is lower (see S1.3.11.1).
S6.4.3 With the test specimen pressurized, subject it to impacts from hammer drop heights of 304.8 mm (1 ft), 914.4 mm (3 ft), and 1524 mm (5 ft). The test criteria shall be in conformance with MIL-S-901 (for Grade A, Class I, Type A, lightweight hull-mounted equipment).
S6.4.4 After completion of high-impact shock test, subject the specimens to a hydrostatic proof test (see Annex A4) followed by a burst test (see Annex A8).
S6.4.5 The test specimens successfully pass high-impact shock testing when they do not show evidence of leakage during the shock test, hydrostatic proof test, and burst test.

S6.5 Precision and Bias
S6.5.1 The precision of the high-impact shock test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the high-impact shock test when the M & TE used is calibrated properly.

S7. FIRE TEST

S7.1 Scope
S7.1.1 Unless otherwise specified, MAFs shall be subjected to a fire test. The amount of specimens required for testing shall be as specified in Table S1.1 (see S1.3.7).
S7.1.2 This test should be used to measure and describe the response of materials, products, or assemblies to heat and flame under controlled conditions and should not be used to describe or appraise the fire hazard or the fire risk of materials, products, or assemblies under actual fire conditions. However, results of this test may be used as elements of a fire hazard assessment or a fire risk assessment which takes into account all the factors that are pertinent to an assessment of the fire hazard or the fire risk of a particular end use.
S7.1.3 Limitation—This fire test is a part of a set of tests used for evaluating the performance characteristics of MAFs. It is not intended for use independently in part or whole (see 1.7).

NOTE S7.1—High pressures created during this test can result in catastrophic failure of the test specimen. Precautions shall be taken to protect personnel and facilities.

S7.2 Significance and Use
S7.2.1 This test establishes a combined exposure of internal pressure and external heat flux to determine the ability of MAFs to withstand a 30-min simulated fire condition. Heat flux instead of temperature was selected because it is a better measure of fire exposure. The pressure and heat flux exposure specified herein represents a specific fire condition that could occur on board ship. The specified exposure is not sufficient to predict the survival of MAFs during all types and sizes of shipboard fires. After the fire test, MAF specimens are subjected to hydrostatic proof tests. MAFs are graded according to the amount of leakage during the hydrostatic tests. The fire test may be used to determine the acceptability of MAFs for use in fire hazardous areas on board ship where fire conditions such as those caused by a flammable liquid fire could occur.
S7.3 General Testing Requirements

S7.3.1 The test specimens may be pneumatically tested (see Annex A3) and hydrostatically tested with water (see Annex A4) at the option of the manufacturer.

S7.3.2 All testing shall be done at a test laboratory acceptable to the purchaser (see S1.3.12).

S7.3.2.1 The fitting manufacturer must submit advance proof of ability of the independent test laboratory to meet the requirements specified by the purchaser (including: facilities, equipment, personnel, instrumentation, and sample data).

S7.3.3 The fire test laboratory shall verify that specimens to be tested are identified properly, conduct all tests, and certify results.

S7.3.3.1 Fire test laboratory personnel shall witness test specimen installation and provide certification of fabrication in accordance with approved written fabrication techniques and procedures.

S7.3.4 After verification of the unique combinations of the fitting family (see S1.3.7), the purchaser may specify one additional random fire test for each manufacturer to include in its test plan.

S7.3.5 The specimens to be tested shall be assembled in accordance with the geometries shown in Fig. 1, except that the minimum pipe or tube length shall be as specified in S7.4.2.

S7.3.5.1 Connection of each MAF to pipe or tube shall be done using the manufacturer’s approved assembly procedures (see S1.3.6).

S7.3.5.2 The MAFs assembled into fire test specimens shall be the same in all respects as the MAFs subjected to other tests herein and in the Annex.

S7.3.6 Any furnace or other apparatus large enough to expose the minimum length of specimen (see 7.4.2) to the required heat flux may be used.

S7.3.6.1 If an electric furnace is used, a thin coat of flat black paint must be applied to each specimen before the fire test.

S7.3.6.2 Multiple specimens may be tested at the same time if the required heat flux exposure of each specimen is assured.

S7.3.7 Any fuel that achieves the required heat flux may be used.

S7.3.8 Install sufficient total heat-flux gages within a 15–cm (6–in.) radial distance of each specimen centerline to measure a spatial average of the total cold wall heat flux at all exposed surfaces of each specimen during all tests. Alternatively, precalibrate the furnace or other apparatus as specified in S7.3.11.

S7.3.8.1 Measure the required heat flux using circular foil heat-flux gages (often call Gardon gages after the developer). The gage must be calibrated and water cooled and must sense total heat flux (radiant and convective).

NOTE S7.3—Test Methods E 511 and E 1529 describe the design and use of circular foil heat flux gages.

S7.3.9 Furnace thermocouples, if used, are to be fabricated by fusion welding the twisted ends of 1.63-mm (0.064-in.) diameter chromel-alumel wires having a time constant of 2 min or less and mounting the wires in porcelain insulators.

S7.3.9.1 The furnace thermocouple assembly is to be inserted through a standard weight 12.7-mm (½-in.) steel or chrome-nickel alloy pipe. The thermocouple junction is to protrude 12.7 mm (½ in.) from the open end of the pipe.

S7.3.10 Heat flux (or temperature) and pressure shall be monitored continuously and recorded at intervals not exceeding 10 s during the first 5 min and every 30 s thereafter.

S7.3.10.1 Measure the internal pressure of MAF specimens with transducers appropriate to each specimen’s test pressure.

S7.3.11 Instead of continuous heat-flux measurement, the furnace or other apparatus may be calibrated to establish a time-temperature curve that provides the required heat flux to each specimen. The calibrated time-temperature conditions must be measured and successfully reproduced in every subsequent material test. Measure temperature and heat flux and follow:

S7.3.11.1 For each specimen location, measure a spatial average of the total cold wall heat flux that would exist at all exposed surfaces of the longest specimen to be tested in that location. Position the heat-flux gages within a 115–cm (6–in.) radial distance of the specimen centerline.

S7.3.11.2 Measure the heating environment temperature with not less than six furnace thermocouples as specified in S7.3.9 symmetrically distributed at the outer boundaries of, but not in contact with, the test specimen(s). Any cage or other safety barrier must be included in the calibration test.

S7.3.11.3 If the furnace or other apparatus has provision for multiple specimens, calibrate each position with all other positions occupied to assure specimens are not shielded from direct impingement of the required flux.

S7.3.11.4 The furnace or apparatus must be recalibrated each time it is repaired or modified or once per year or every 300 test h, whichever is first.

S7.4 Procedure

S7.4.1 Pressurize and instrument each specimen separately, except that the specimens requiring the same test pressure may be manifolded. When a manifold is used, any leakage invalidates the fire test for all specimens manifolded. See S1.3.9 for further instructions.

S7.4.1.1 Specimens shall be unrestrained at one end to allow for expansion.

S7.4.1.2 Assembly supports shall be beyond the minimum specimen exposure length specified in S7.4.2.

S7.4.2 Expose a fitting with pipe or tube length at each outlet as follows:

S7.4.2.1 If the entire pipe or tube length is exposed to the required heat flux, the minimum length of that pipe or tube shall be three outside diameters.

S7.4.2.2 If any pipe or tube extends beyond the area of required heat flux, the length of the pipe or tube actually exposed to the required heat flux shall be a minimum of ten outside diameters.

S7.4.2.3 Less pipe or tube length may be exposed if screening tests prove that the fitting heats at the same rate with less pipe exposed to the required heat flux.

S7.4.3 The specimen test pressure shall be the rated pressure of the MAF or the temperature-adjusted rated pressure \( P_{\text{TEMP}} \) of the pipe or tube, whichever is lower.
S7.4.3.1 Calculate the temperature-adjusted rated pressure for the appropriate pipe or tube material being tested using the following formula:

\[ P_{\text{TEMP}} = F_s \times \frac{2 \times \sigma_{\text{TEMP}}}{\text{OD}} = \frac{t_{\text{min}} \times \sigma_{\text{TEMP}}}{\text{OD}} \]

where

- \( F_s \) = 0.5 factor of safety,
- \( t_{\text{min}} \) = minimum wall thickness,
- \( \sigma_{\text{TEMP}} \) = temperature-adjusted yield strength of the pipe or tube at 927°C (1700°F) (see S7.4.3.2), and
- \( \text{OD} \) = outside diameter of pipe or tube.

S7.4.3.2 Use the following temperature-adjusted yield strength (\( \sigma_{\text{TEMP}} \)) values for the calculation of \( P_{\text{TEMP}} \) specified in S7.4.3.1:

<table>
<thead>
<tr>
<th>Material</th>
<th>( \sigma_{\text{TEMP}} )</th>
</tr>
</thead>
<tbody>
<tr>

<td>41.00 MPa (6.000 ksi)</td>
</tr>
<tr>
<td>CUNI (70/30)</td>
<td>11.00 MPa (1.600 ksi)</td>
</tr>
<tr>
<td>CUNI (90/10)</td>
<td>8.00 MPa (1.200 ksi)</td>
</tr>
<tr>
<td>Copper</td>
<td>1.00 MPa (0.150 ksi)</td>
</tr>
</tbody>
</table>

S7.4.4 Pressurize the specimens with nitrogen (\( \text{N}_2 \)) or dry air. Control the pressure of the gas as follows:

S7.4.4.1 Before the fire exposure, precharge each specimen with an estimated mass of gas such that after 5 min the total pressure of expanding gas inside the heated specimen will reach 100 ± 10% of the specimen test pressure. Verify there is no leakage.

S7.4.4.2 During the first 5 min of fire exposure, allow specimen pressure to rise uncontrolled up to 110% of the test pressure. If necessary, bleed out gas to maintain 100 ± 10% of the test pressure.

S7.4.4.3 After 5 min of fire exposure, control specimen pressure to maintain 100 ± 5% of the test pressure until 20 min of fire exposure.

S7.4.4.4 After 20 min of fire exposure, close the valves controlling specimen pressure to seal the specimens.

S7.4.4.5 A safety relief valve may be used throughout the fire exposure. If a relief valve is used, the opening pressure setting shall be at least 10% above the test pressure. Instrument the relief valve and record the opening times.

S7.4.4.6 After 20 min of fire exposure, pressure variations within each MAF specimen as a result of variations in specimen gas temperature or specimen volume shall be within ±10% of the specimen test pressure.

S7.4.5 Conduct the fire test in a manner that will allow for a rapid temperature rise to attain the required heat flux.

NOTE S7.4—See Test Method E 1529 for background information on the fire exposure.

S7.4.5.1 The fire exposure shall provide a spatial average total cold wall heat flux of at least 120 kW/m² within 3 min to all exposed surfaces of each specimen and maintain +20 and −0% of that flux throughout the remainder of the test.

S7.4.5.2 Expose each specimen in an environment meeting the fire requirements (see S7.4.5) for 30 min.

S7.4.6 If there is any leakage during the 30-min fire period, the fire test is invalid. See S1.3.9 for further instructions.

S7.4.7 Immediately after completing the fire exposure, allow the test specimens to cool to ambient temperature. Upon attaining room temperature, subject the test specimens to a hydrostatic proof test.

S7.4.7.1 Conduct the hydrostatic proof test in accordance with the requirements specified in Annex A4 except for the following:

1. Fill the specimens with clean fresh water.
2. Pressurize the test specimen to 150% of rated pressure and maintain pressure for at least 30 min.
3. Perform the hydrostatic proof test in the same test laboratory as the fire test.
4. Measure the total accumulated leakage of the hydrostatic proof test.

S7.4.7.2 Total accumulated leakage from the fitting for the duration of the hydrostatic proof test shall be classified with the following grades:

<table>
<thead>
<tr>
<th>Grade</th>
<th>Amount of Leakage, mL</th>
</tr>
</thead>
<tbody>
<tr>
<td>L-0</td>
<td>0 (None)</td>
</tr>
<tr>
<td>L-10</td>
<td>&gt;0 and &lt;10</td>
</tr>
<tr>
<td>L-50</td>
<td>&gt;10 and &lt;50</td>
</tr>
<tr>
<td>Failure</td>
<td>&gt;50</td>
</tr>
</tbody>
</table>

\( ^a \) Total accumulated leakage for the duration of the postfire hydrostatic test.
\( ^a \) Symbol “>” means “greater than.” Symbol “<” means “less than or equal to.”

S7.4.8 The test specimen fails if there is leakage greater than or equal to 50 mL at the fitting joint or within one diameter of the fitting joint during the post-fire or hydrostatic test.

S7.4.8.1 Failure of the pipe away from the fitting does not disqualify a fitting. Failure within one diameter of the fitting constitutes failure of the fitting unless it is shown by tests of pipe alone that the fitting is not likely to have contributed to the pipe failure.

S7.4.9 Complete the test report for the fire test in accordance with S1.3.13.

S7.5 Precision and Bias

S7.5.1 The precision of the fire test is established by the accuracy of the test equipment (see 7.5) and permissible tolerances used during the test. There is no bias when the equipment used is properly calibrated to measure accurate results.
S8. VIBRATION TEST

S8.1 Scope

S8.1.1 When invoked by the purchaser, MAFs shall be subjected to a vibration test. The number of specimens used shall be as specified in Table S1.1.

S8.2 Significance and Use

S8.2.1 This test determines the ability of MAFs to withstand the effects of vibration while being pressurized. After completion of this test, the specimen is subjected to a hydrostatic proof test. This test is used to duplicate conditions that could occur during in-service use.

S8.3 General Testing Requirements

S8.3.1 The test specimen geometry may be in accordance with Fig. 1. The location of strain gages shall be on the high side of the specimen to within 4.6 mm (0.18 in.) as shown in Fig. 1.

S8.3.2 Before beginning the vibration test, the test specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.

S8.3.3 The selected specimens shall be filled with fluid in accordance with 7.6.3 before being placed onto the appropriate test fixture.

S8.3.3.1 The test fixture shall be equipped with supports to be attached to the test specimen during testing. The supports shall be spaced as shown in Fig. S8.1. The distance between supports shall be as specified in Table S8.1.

S8.3.4 The testing frequency ranges applied and vibration amplitudes attained shall be recorded in the test report for each of the tests performed.

S8.3.5 The specimens shall show no evidence of leakage during or at the completion of the test.

S8.3.6 At completion of testing, the test specimens shall be subjected to a hydrostatic proof test in accordance with the requirements specified in Annex A4.

S8.3.7 The specimens successfully pass the vibration test after meeting the test requirements herein and passing the subsequent hydrostatic proof test (see Annex A4).

---

S8.4 Procedure

S8.4.1 Subject MAF to a vibration test in accordance with MIL-STD-167 (Type I: Environmental).

S8.4.2 Conduct the test in each of the three principle directions (X, Y, and Z).

S8.4.3 Conduct and complete testing in one direction before proceeding to the other.

S8.4.4 Pressurize the specimens to 100% of the rated pressure of the pipe or tube or fitting, whichever is lower (see S1.3.11.1).

S8.4.5 The test apparatus shall be able to record any drop in pressure throughout the duration of the test. If pressure is lost at any time during the test and is due to leakage at the MAF joint, the specimens have failed (see S1.3.9).

S8.4.5.1 If there is a loss of pressure through faulty equipment or on the test specimen in any area other than the MAF joint, note this occurrence in the test report, but it is not to be considered as a failure of the MAF.

S8.4.6 Perform the following tests: exploratory vibration test, variable frequency test, and endurance test.

S8.5 Precision and Bias

S8.5.1 The precision of the vibration test is established by the accuracy of the test equipment (7.5.1.1) and permissible tolerances used during the test. There is no bias when the equipment used is calibrated properly to measure accurate results.
A1. PERFORMANCE TESTS FOR MAF

A1.1 Scope

A1.1.1 This section lists the tests to be used to verify whether MAFs meet the performance characteristics of this specification. In addition, any statements that would apply to all tests are specified in this section to minimize redundancy.

A1.1.2 The test procedures appear in the following order:

- Examination of Specimen
- Pneumatic Proof Test
- Hydrostatic Proof Test
- Impulse Test
- Flexure Fatigue Test
- Tensile Test
- Hydrostatic Burst Test
- Repeated Assembly Test
- Rotary Flex Test
- Mercurous Nitrate Test

A1.1.3 The sections of the main body of this specification listed below apply to the test specimens used to perform the tests listed in A1.1.2.

A1.2 Significance & Use

A1.2.1 List of All Tests—Section A1.1.3 and Table 1 provide a listing of all tests specified herein. The requirements for each test are as specified in Annex A2-Annex A10.

A1.2.2 General Information—All of the general information which applies to the tests described shall be as specified in A1.3.

A1.3 General Testing Requirements

A1.3.1 The test temperatures shall be as specified in each individual test.

A1.3.2 Tests may be performed by the manufacturer or by a test facility designated by the manufacturer and approved by the purchaser. In all cases, the testing apparatus used to test MAFs shall be calibrated in accordance with the requirements specified in 7.5.1.

A1.3.3 End caps or adapters used to connect the test specimen assembly to the test apparatus, or plugs used to block off a specimen end, shall be an optional design designated by the manufacturer. The end caps or adapters shall be constructed as to prevent their failure during testing.

A1.3.4 Failure of any test specimen which is related to separation or leakage at the joint of the end cap or adapter and pipe or tube shall be recorded in the test report but shall not be considered a failure of the MAF pipe or tube combination being tested. Replacement test specimens shall be prepared in accordance with Section 12.

A1.3.5 Failure of the MAF during testing through causes which are determined to be related to the MAF design shall be dispositioned in accordance with the requirements specified in 11.3.1. When penalty specimens are used, they shall be prepared and identified in accordance with 11.3.2. If the penalty specimens successfully pass all required testing, the initial failure shall be reported but shall not be considered an issue against the approval for technical qualification of the MAF design.

A1.3.6 MAF test specimen(s) shall be assembled in accordance with the manufacturer’s recommended procedures.

A1.3.7 When multiple tests are performed on individual specimens, the sequence of testing shall be as specified in the test description.

A1.3.8 MAFs meet the requirements of this specification after successfully passing all of tests described in Annex A2-Annex A10. When required, the mercurous nitrate test specified in Annex A11 shall also be passed.

A1.4 Precision and Bias

A1.4.1 No statement is made about either the precision or bias of Annex A1, since the result merely states whether there is conformance to the criteria for success specified in the procedure.

A2. EXAMINATION OF SPECIMEN

A2.1 Scope

A2.1.1 This procedure covers the inspection and examination of test specimens prepared in accordance with the requirements specified in Section 12.

A2.2 Significance and Use

A2.2.1 MAFs are attached to and onto pipe(s) or tube(s), or both, using a variety of methods (see 1.1). To ascertain the integrity of each MAF type covered, it becomes important to
subject all types of MAFs to essentially the same tests. When the same tests are used, the assembly of the test specimens becomes critical to the results of each test performed. The usefulness of this procedure lies in the examination of MAF test specimens to ensure that resulting geometries duplicate appropriate stresses on all types of MAFs qualified using the tests specified herein.

A2.3 Procedure

A2.3.1 Assemble MAF test specimens in accordance with the manufacturer’s assembly procedures as approved by the purchaser (see 12.1).

A2.3.2 Inspect the test specimen dimensionally to ensure that it is in compliance with the specimen geometry specified in Fig. 1.

A2.3.3 Inspect strain gauges (when required) to ensure their location on the test specimen as shown in Fig. 1. They shall be calibrated to assure their ability to transmit accurate readings and data to the equipment being used during the appropriate test.

A2.3.4 The materials used to assemble the test specimens shall be in accordance with Section 12. The schedule or the nominal wall thickness of the pipe or tube may vary as recommended by the manufacturer for a single MAF size. This will permit the compatible pipe or tube throughout its given size range to be qualified along with the MAF.

A2.3.5 Quality and workmanship of the test specimens shall be in accordance with the requirements specified in Section 9.

A2.3.6 End caps or adapters used to connect the test specimen to subsequent testing apparatus shall be designed by the manufacturer or its designated testing facility.

A2.3.6.1 MAF specimens prepared for mercurous nitrate testing do not require end caps to be installed.

A2.3.7 During visual examination of the test specimens, record any unusual circumstances in accordance with the requirements specified in 14.6.

A2.3.8 Record the following information in the test report (or form) at the time of examination: date examined, MAF part number, specimen part number, pipe or tube material, outside diameter, wall thickness, and intended use.

A2.4 Precision and Bias

A2.4.1 Precision is based upon the accuracy of the MAF dimensions in accordance with applicable drawings. The pipe or tube used in conjunction with MAF must be in accordance with the raw material specification recommended by the manufacturer. There may be bias for the examination of specimens based upon the human elements involved in the visual inspection methods used.

A3. PNEUMATIC PROOF TESTING (OPTIONAL)\(^\text{16}\)

A3.1 Scope

A3.1.1 This section covers pneumatic proof testing of all MAF test specimens (except mercurous nitrate) as specified in Table 3. All specimens approved for testing shall be subjected to this test.

A3.2 Significance and Use

A3.2.1 This test is the initial test of all MAF specimens prepared for testing. The test is performed by pressurizing the test specimen(s) using dry air or nitrogen (N\(_2\)). The initial pressure of 0.690 MPa (100 psi) is applied. If there is no leakage, the pressure is gradually increased to 125 % rated pressure of the pipe or tube or 3.45 MPa (500 psi), whichever is lower. If the specimen still shows no evidence of leakage after the second pressurization period, the specimen has successfully passed the test. This test is useful in determining if the MAF pipe or tube connection has been assembled correctly or if the MAF design performs as intended at elevated pressure.

A3.3 Procedure

A3.3.1 Place the test specimen in an appropriate chamber and secure it in place in accordance with the manufacturer’s recommended procedures.

---

\(^{16}\) This test is optional as to whether it is performed before all other testing.
bubbles during initial pressurization), the test specimens have passed the pneumatic proof test.

A3.4 Precision and Bias
A3.4.1 The precision of the pneumatic proof test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the pneumatic proof test when the M & TE used is calibrated properly.

A4. HYDROSTATIC PROOF TESTING (OPTIONAL)\(^{16}\)

A4.1 Scope
A4.1.1 This section covers hydrostatic proof testing of selected MAF test specimens (except mercurous nitrate) as specified in Table 3. All specimens prepared for testing shall be subjected to this test.

Note A4.1—Caution: Those specimens selected for fire testing shall be hydrostatically proof tested using water only.

A4.2 Significance and Use
A4.2.1 This test is performed by pressurizing the test specimens using hydraulic fluid or water (see Note A4.1). The initial pressure applied, 0.690 MPa (100 psi), tests the assembled specimen to determine if it can retain fluid without leakage at the pipe or tube and MAF joint. If there is no leakage, the pressure is gradually increased to a second pressurization period of 150 % rated pressure of the pipe or tube or MAF, whichever is lower. This elevated pressure level tests the ability of the specimens to hold fluid without leakage.

A4.2.2 If the specimen still shows no evidence of leakage after the second pressurization period, the specimens have passed the test. This test is useful in determining the integrity of the MAF joint to hold fluid at an elevated pressure without leakage. After successful completion of this test, the test specimens are ready for additional testing.

A4.3 Procedure
A4.3.1 Fill the test specimens with fluid which meets the requirements of 7.6.3 before installation onto the appropriate testing apparatus.

A4.3.2 Place the test specimens in a burst chamber and secure into place in accordance with the manufacturer’s recommended procedures. One end of the test specimen shall be free to move.

A4.3.3 Equip the chamber with calibrated pressure gages (see 7.5.1) to permit visual readings of actual pressure being applied.

A4.3.4 Perform the hydrostatic proof test at ambient temperature.

A4.3.5 Initially pressurize the test specimens to 0.690 MPa (100 psi) ± 5 % for a total period of 5 min. There shall be no evidence of leakage during this 5-min period. If leakage occurs, discontinue the test. The affected specimens have failed the test. Fill out the test report noting the reason for discontinuing the test. See A1.3.4 or A1.3.5 for further information.

A4.3.6 If there is no evidence of leakage after the initial 5-min period (see A4.3.5), gradually increase the pressure at an average rate not to exceed 172 MPa/min (25 000 psig/min) to 150 ± 5 % of the rated pressure of the pipe or tube or MAF, whichever is lower. Maintain this pressure for an additional period of 5 min. There shall be no evidence of leakage during this 5-min period. If leakage occurs, discontinue the test. The affected specimens have failed the test. Fill out the test report noting the reason for discontinuing the test. See A1.3.4 and A1.3.5 for further information (as applicable).

A4.3.7 If there is no evidence of leakage within the MAF or MAF joint during both pressurized periods, the test specimens have passed the hydrostatic proof test. The specimens are ready for further testing.

A4.4 Precision and Bias
A4.4.1 The precision of the hydrostatic proof test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the hydrostatic proof test when the M & TE used is calibrated properly.

A5. IMPULSE TESTING

A5.1 Scope
A5.1.1 This section covers impulse testing of selected MAF test specimens. The number of specimens tested shall be as specified in Table 3 using the applicable specimen geometries shown in Fig. 1.

A5.1.1.1 At least 50 % of the separable specimens (Types II, III, and IV) shall be used for repeat assembly testing before testing begins, during the testing period, and after the test is concluded (see Annex A9).

A5.2 Significance and Use
A5.2.1 This test is performed by filling the test specimens with hydraulic fluid or water. The maximum pressure attained during the impulse cycle shall be 133 % of the performance pressure. The specimen is then depressurized to a pressure not greater than 20 ± 5 % of the performance pressure. Each period of pressurization/depressurization is equal to one impulse cycle. The test specimens must be subjected to one million (106) cycles without leakage.
A5.2.2 If the test specimens show no evidence of leakage after completion of the impulse testing, they have passed. If any specimens fail during the course of this test, the test for the failed specimens must be discontinued and the reason for the failure noted in the test report (see A1.3.5).

A5.2.3 All passed specimens shall then be subjected to a hydrostatic proof test as specified in Annex A4. This impulse test is useful to verify the ability of the MAF joint to maintain integrity in the presence of fluctuating system pressure. The occurrences during impulse testing simulate environments that may exist in hydraulic or hydrostatic piping or tubing systems for which MAF is designed.

A5.3 Procedure

A5.3.1 Fill the test specimens with hydraulic fluid which meets the requirements of 7.6.3 before installation onto the appropriate test apparatus.

A5.3.2 Perform the test at ambient conditions throughout the testing period.

A5.3.3 Connect the test specimens onto a testing apparatus that is capable of applying a pressure of 133 ± 5% of the performance pressure of the pipe or tube or MAF, whichever is lower, followed by a depressurization to a pressure not greater than 20 ± 5% of the performance pressure.

A5.3.4 Equip the apparatus with calibrated instruments (see 7.5.1) which permit visual readings of the actual pressures being applied to the specimens throughout the test period.

A5.3.5 Subject the test specimens to impulse pressures at the range specified in A5.3.3. Each application of maximum and minimum pressure shall be equal to one impulse cycle.

A5.3.6 The duration of impulse testing shall be 10⁶ cycles at a rate not to exceed 75 cycles per minute (CPM).

A5.3.7 After the completion of the impulse test, hydrostatically proof test the test specimens in accordance with the requirements specified in Annex A4.

A5.3.8 There shall be no evidence of leakage during impulse testing or hydrostatic proof testing. If leakage occurs during either testing period, discontinue the test. The affected specimens have failed the test. Fill out the test report noting the reason for discontinuing the test. See A1.3.4 and A1.3.5 for further information.

A5.3.9 If there is no evidence of leakage at the conclusion of impulse or hydrostatic proof testing, the specimens have passed.

A5.4 Precision and Bias

A5.4.1 The precision of the impulse test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There is no bias in the impulse test when the M & TE used is calibrated properly.

A6. FLEXURE FATIGUE TEST

A6.1 Scope

A6.1.1 This section covers the requirements for flexure fatigue testing of selected test specimens as specified in Table 3. The specimen geometry used shall be as selected from Fig. 1.

A6.1.1.1 At least 50% of the separable specimens (Types II, III, and IV) shall be used for repeat assembly testing specified in Annex A9.

A6.2 Significance and Use

A6.2.1 The significance of this test is to verify the capability of the MAF joint to perform adequately at rated pressure in a flexure environment. The test specimen is subjected to flexure while being pressurized to the maximum rated pressure of the pipe or tube or MAF, whichever is lower. The specimen is subjected to a bidirectional flexure whose plus (+) and minus (−) magnitudes are equal to within 2%. This test is useful in simulating environmental conditions which may exist in fluid systems for which MAF is designed.

A6.2.2 If the specimens do not show signs of leakage, they are subjected to a hydrostatic proof test as specified in Annex A4. The specimen passes when there is no evidence of leakage after the flexure fatigue test and hydrostatic proof test.

A6.3 Procedure

A6.3.1 Fill the test specimens with hydraulic fluid which meets the requirements of 7.6.3 before installation onto the appropriate testing apparatus.

A6.3.2 Equip the apparatus with calibrated gages (see 7.5.1) which permit visual readings of the actual pressures being applied. The apparatus shall be designed to shut down in the event that pressure is lost during the period of the test.

A6.3.3 Locate calibrated strain gages on the high stress side of the pipe or tube as shown in the geometries in Fig. 1. They shall be able to transmit accurate data to calibrated equipment which will be capable of displaying visual data or recording physical data, or both, throughout the period of the test.

A6.3.4 Conduct the test at ambient conditions throughout the testing period.

A6.3.5 Calculate the axial stress introduced as a result of the internal pressure to be applied using the following formula:

\[ S = \frac{Pd^2}{D^2 - d^2} \]

where

\[ S = \text{stress}, \]

\[ P = \text{pressure}, \]

\[ D = \text{outside diameter}, \]

\[ d = \text{inside diameter}. \]

*A total axial stress as a result of combined pressure and bending.*

**A7. TENSILE TEST**

**A7.1 Scope**

A7.1.1 This section covers the requirements for tensile testing selected specimens as specified in Table 3. The number of specimens for this test shall be as specified in Table 3, using the specimen geometries as shown in Fig. 1.

**A7.2 Significance and Use**

A7.2.1 The significance of this test is to apply a tensile load at a controlled separation speed to establish how much load is needed to separate the test specimen. The minimum tensile load occurs during separation of the pipe or tube and MAF joint. The amount of tensile load applied depends upon the cross-section area and the yield strength of the pipe or tube. The formula specified in A7.3.3 constitutes the criterion for the pass or fail requirements of this test. When the minimum tensile load is calculated, the result should be equal to or less than the minimum tensile load required to achieve separation of the specimen joint. Failure occurs when separation takes place at a point before the calculated tensile load is applied. If failure occurs, the test shall be discontinued, and the test report shall be noted with the reason for discontinuing the test.

A7.2.2 The specimens pass this test when the calculated tensile load is achieved without separation of the joint. Movement within the area of the joint is acceptable as long as actual separation does not occur. This test is useful in determining the strength of the pipe or tube or MAF joint. Based upon the strength of the joint, the pipe or tube material and wall thickness can be tailored to withstand failure within the adverse environments present in fluid systems for which MAF is designed.

**A7.3 Procedure**

A7.3.1 Before tensile testing, the specimens may be subjected to a pneumatic test (see Annex A3) and a hydrostatic test (see Annex A4) at the option of the manufacturer.

A7.3.2 Install each test specimen in a constant strain rate tensile machine. The gripping jaws shall be located a minimum of three pipe or tube diameters from the MAF joint.

A7.3.3 The constant strain rate tensile machine shall have the capability to apply a constant tensile load which will result in establishing a speed of approximately 1.3 mm/min (0.05 in./min) at which cross head minimum tensile pull out force (as separation occurs) will be attained. Minimum allowable tensile
load is based upon being equal to or greater than the values stated in the following formula:

\[
\text{Calculated tensile load} = (Kt) \times (Ap) \times (Sy)
\]

where

\[Kt\]  = tensile constant of 1.0;
\[Ap\]  = actual cross-section area of the pipe, mm\(^2\) (in.\(^2\)) based on wall thickness; and
\[Sy\]  = minimum specified yield strength of pipe or tube.

A7.4 Precision and Bias

A7.4.1 The precision for the tensile test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There may be bias in the tensile test when separation occurs at a point other than at the MAF joint. If the pipe or tube were to yield before the MAF pipe or tube joint, this would establish that the pipe or tube is weaker than the MAF. In this case, a stronger yield of pipe or tube may be needed to determine the strength of the joint. In another instance, the MAF may yield before the joint or pipe or tube. If this is the case, reevaluation of the pipe or tube selected may have to be reconsidered to establish the true strength of the MAF joint.

A8. HYDROSTATIC BURST TEST

A8.1 Scope

A8.1.1 This section covers the test requirements for burst testing. The number of specimens to be tested shall be as specified in Table 3.

A8.1.1.1 When the Supplementary Section is invoked, passed specimens from the elevated temperature soak test (S3) and shock test (S6) shall be used instead of new or previously tested specimens from tests specified in the Annex.

A8.2 Significance and Use

A8.2.1 The significance of this test is two-fold. The first significant aspect is the burst test itself. This test verifies the integrity of the pipe or tube and MAF joint to withstand, without leakage or burst, a minimum pressure equal to four times the rated pressure of the pipe or tube or MAF, whichever is lower. To pass this test, the pipe or tube and MAF joint cannot leak or burst below four times the rated pressure.

A8.2.2 The second significant aspect of this test is the test specimens used. All test specimens are comprised of those specimens which have passed other tests as specified in A8.1.1. The use of this test determines whether the MAF design may ultimately receive technical approval for in-service systems by the purchaser.

A8.3 Procedure

A8.3.1 Fill the test specimens with water or hydraulic fluid which meets the requirements of 7.6.3 before installation onto the appropriate testing apparatus.

A8.3.2 Place the test specimens into a burst chamber and secure them into place in accordance with the manufacturer’s recommended procedures. One end must be free to move.

A8.3.3 Equip the chamber with calibrated pressure gages (see 7.5.1) to permit visual readings of actual pressure being applied.

A8.3.4 Perform the hydrostatic burst test at ambient temperature.

A8.3.5 Subject the test specimens to a gradual increase of pressure at an average rate not to exceed 127 MPa/min (25 000 psig/min) to four times the rated pressure of the specimen assembly and hold for a minimum of 1 min. If leakage or burst occurs below four times the rated pressure of the specimen assembly, discontinue the test. The affected test specimens have failed the test. Fill out the test report noting the reason for discontinuing the test. See A1.3.4 and A1.3.5 for further information.

A8.3.6 The test specimens have passed the hydrostatic burst test when four times the rated pressure of the specimen assembly has been attained.

A8.4 Precision and Bias

A8.4.1 The precision of the hydrostatic burst test is established by the accuracy of the measuring and test equipment (M & TE) and their permissible tolerances during the test (see 7.5). There may be bias in this test if the pipe or tube selected burst below four times its rated pressure. If this should occur, the test specimens shall be replaced in accordance with A1.3.4. There may be no bias in this test if the precision of the gages used is the only determining factor. The gages used to apply a gradual increase pressure to a maximum of four times the rated pressure of the specimen assembly, can be read accurately during the test period.
A9.1 Scope

A9.1.1 This section covers the requirements for repeat assembly testing of selected test specimens as specified in Table 3. This test is only applicable to separable MAFs, Types II, III, and IV. Test specimens selected for repeat assembly shall be comprised of at least 50% of the specimens from impulse (see Annex A5) and flexure fatigue (see Annex A6) tests.

A9.2 Significance and Use

A9.2.1 The significance of this test is to verify the integrity of the separable MAF joint to withstand ten repeated assemblies. The disassembly and reassembly shall be performed using the manufacturer’s recommended assembly procedures. The test specimens used for repeat assembly shall be selected from the impulse and flexure tests. An equal amount of specimens shall be selected from each of these tests. Scoring, distortion, damage, or modification of the mating parts of the MAF joint as a result of repeated assembly shall not be cause for failure.

A9.2.2 If the specimens show no evidence of leakage during impulse and flexure testing (or their posttest requirements), they pass the repeat assembly test.

A9.3 Procedure

A9.3.1 Before beginning the impulse or flexure fatigue test, disassemble and reassemble the separable MAF assembly one time.

A9.3.1.1 Each assembly shall have the sealing face rotated by hand 60 to 90° before each reassembly.

A9.3.2 At the conclusion of 25% of the test cycles for impulse and flexure fatigue test, interrupt the test and disassemble and reassemble the test specimens two more times (see A9.3.1.1).

A9.3.3 At the conclusion of 50% of the test cycles for impulse and flexure fatigue test, interrupt the test and disassemble and reassemble the test specimens two more times (see A9.3.1.1).

A9.3.4 At the conclusion of 75% of the test cycles for impulse and flexure fatigue test, interrupt the test and disassemble and reassemble the test specimens two more times (see A9.3.1.1).

A9.3.5 At the conclusion of the impulse and flexure fatigue test (before post testing), disassemble and reassemble the test specimens an additional two times (see A9.3.1.1).

A9.3.6 If the test specimens show no evidence of leakage after the post-test requirements for impulse and flexure fatigue, they have passed the repeated assembly test.

A9.3.7 If the specimens leak any time during the test, discontinue the test. The affected specimens have failed the test. Note the reason for discontinuing the test in the test report. See A1.3.4 and A1.3.5 for further information (as applicable).

A9.4 Precision and Bias

A9.4.1 There is no precision and bias for the repeated assembly test because scoring, distortion, damage, or modification of the sealing surfaces are not causes for failure of this test. The precision and bias statements for subsequent hydrostatic proof, impulse, and flexure fatigue tests apply.

A10. ROTARY FLEX TEST

A10.1 Scope

A10.1.1 When invoked by the purchaser, Types II, III, and IV MAFs shall be subjected to a rotary flex test. This test shall only apply to MAFs with tube diameters of 25.4 mm inclusive (1 in. inclusive) or less. The number of specimens used shall be as specified in Table 3.

A10.2 Significance and Use

A10.2.1 This test determines the ability of separable MAFs to withstand the effects of rotary flex while being pressurized. After completion of this test, the specimen is subjected to a hydrostatic proof test. This test is used to duplicate conditions that could occur during in-service use.

A10.3 General Testing Requirements

A10.3.1 The test specimen geometry shall be in accordance with Fig. 1. The location of strain gages shall be on the high side of the specimen to within 4.6 mm (0.18 in.) as shown.

A10.3.2 Before beginning the test, the specimens may be tested pneumatically (see Annex A3) and hydrostatically (see Annex A4) at the option of the manufacturer.

A10.3.3 The selected specimens shall be filled with fluid in accordance with 7.6.3 before being placed onto the appropriate test fixture.

A10.3.4 The testing frequency ranges applied and amplitudes attained shall be recorded in the test report for each of the tests performed.

A10.3.5 The specimens shall show no evidence of leakage during or at the completion of the test.

A10.3.6 At completion of testing, the test specimen shall be subjected to a hydrostatic proof test in accordance with the requirements specified in Annex A4.

A10.3.7 The specimens successfully pass after meeting the rotary flex test requirements and passing the hydrostatic proof test (see Annex A4).
A10.4 Procedure

A10.4.1 Subject selected separable test specimens to a rotary flexure test. The general test requirements specified in A10.3 apply before beginning the test.

A10.4.2 Fill the specimen with fluid in accordance with 7.6.3, and install the specimen onto the appropriate test apparatus which will allow for a bending moment to be introduced along with the application of pressure (see Fig. A10.1).

A10.4.3 With the specimen unpressurized, a bending moment equivalent to a minimum of 35% of the ultimate tensile strength (of the tubing material) shall be introduced and locked into place. Record the bending moment selected in the test report.

A10.4.4 With the bending moment locked into place, pressurize the specimen to a static pressure of 3.45 MPa (500 psi) minimum. Maintain the bending moment and pressure for the duration of the test.

A10.4.5 Select the amplitude to be used and record it in the test report.

A10.4.6 Flex the specimen in a rotary motion at a minimum of 1750 rpm for a minimum of $10^6$ cycles maintaining the specified bending stress level (see A10.4.3) and pressure (see A10.4.4) at all times.

A10.4.7 The test apparatus shall be able to record any loss of pressure throughout the duration of the test.

A10.4.8 If pressure is lost at any time during the test, the specimen has failed. See A1.3.4 and A1.3.5 for further instructions (as applicable).

A10.4.9 At the conclusion of the rotary flex test, subject the specimens to a hydrostatic proof test (see Annex A4) as specified in A10.3.6. Specimens pass the test upon successfully completing the rotary flex test and the hydrostatic test without any leakage.

A11. MERCURIOUS NITRATE TEST

A11.1 Scope

A11.1.1 This section covers the requirements for conducting a mercurious nitrate test of selected MAF specimens as specified in Table 3. The selection of specimens for this test is restricted to those specimens that are manufactured using either copper-zinc (containing more than 15% zinc) or copper-aluminum alloys.

NOTE A11.1—Warning: All appropriate safety precautions, such as the use of rubber gloves, should be taken while handling and testing with mercury. Care should be taken to prevent mercury contamination of other test specimens.

A11.2 Significance and Use

A11.2.1 The significance of this test is to determine the susceptibility to stress-corrosion cracking of MAFs manufactured from materials specified in A11.1.

A11.3 Procedure

A11.3.1 Use two MAFs from the same material lot from which the specimens are selected to conduct this test.

A11.3.2 Assemble the specimens onto pipe or tube to duplicate the geometries shown in Fig. 1. End caps are not required.

A11.3.3 Immerse the MAF specimen for 30 min in a standard mercurious nitrate solution as specified in Test Method B 154.

A11.3.4 Rinse and dry the MAF before immediate examination. There shall be no cracks.

A11.3.5 MAFs successfully pass this test when no cracks are observed during the examination.

A11.4 Precision and Bias

A11.4.1 The precision of this test is the solution and the material tested. There may be bias if the solution is not properly mixed in accordance with Method B 154.
Standard Specification for
Water Trap for Diesel Exhaust

This standard is issued under the fixed designation F 1431; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the material, dimensions, and construction of diesel exhaust water traps, which shall be required whenever the exhaust is to be expelled through the hull of the vessel.

1.2 The traps are designed to prevent sea backwash from entering the diesel exhaust system.

1.3 The values stated in SI (metric) units shall be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:
B 443 Specification for Nickel-Chromium-Molybdenum-Columbium Alloy (UNS NO6625) Plate, Sheet, and Strip
F 104 Classification System for Nonmetallic Gasket Materials
2.2 Military Standard:
MIL-S-901 Requirements for Shock Tests, High Impact, Shipboard Machinery, Equipment and Systems
2.3 Other Documents:
American Bureau of Shipping Rules for Building and Classing Steel Vessels
American Welding Society Publication AWS D1.1 Structural Welding Code

3. Ordering Information

3.1 Water traps ordered under this specification shall include the following information:

3.1.1 ASTM designation, title and date of this specification,
3.1.2 Quantity,
3.1.3 Size,
3.1.4 Shock test and grade (see Supplementary Requirement S1),
3.1.5 Handhole shall be at 45° unless otherwise specified, and
3.1.6 Flange dimensions shall be indicated for gaskets.

4. Materials and Manufacture

4.1 Materials:
4.1.1 The tank and baffles shall be of nickel-chromium-molybdenum-columbium alloy and tested in accordance with Specification B 443.
4.1.2 Gaskets—Gaskets shall be ASTM Classification F 104 (F712100–A9B4–E22K5M6) and shall withstand temperatures of 650°C (1200°F).
4.2 Manufacture:
4.2.1 Construction of the water traps shall be in accordance with this specification and Fig. 1.
4.2.2 Welding shall be in accordance with the American Bureau of Shipping Rules for Building and Classing Steel Vessels or the American Welding Society Publication AWS D1.1.

5. Requirements

5.1 Water traps for diesel exhaust systems shall be designed for maximum temperatures of 650°C (1200°F).

5.2 Baffles:
5.2.1 No less than three baffles shall be installed. The bottom baffle shall not extend below the top of the outlet pipe, as shown in Fig. 1.
5.2.2 The inlet may be rotated about the centerline of the trap to suit the installations. The top baffle shall also be rotated to retain the same relation with the inlet as shown in Fig. 1.

5.3 Trap Size:
5.3.1 The trap size shall be a minimum of 1 m (3 ft) high.
5.3.2 The diameter shall equal twice the diameter of the inlet exhaust line.
5.3.3 The minimum free area through the trap shall equal twice the area of the outlet exhaust line.

5.4 Hand Hole—The hand hole shall be configured as indicated in Fig. 1.
6. Dimensions
6.1 The dimensions in Fig. 1 are recommended nominal dimensions.

7. Workmanship, Finish, and Appearance
7.1 Workmanship on traps and piping shall be of sufficient quality to prevent dirt accumulation. Welding shall have small, even beading, free of slag and spatter.
7.2 The trap shall be free of paint.

8. Test Method
8.1 Each trap shall be pneumatically proof tested 35 kPa (5 psi) with no visible seam leakage.

9. Packaging
9.1 The water traps shall be crated or packaged individually for shipment by a commercial common carrier.
9.1.1 Talc and talcum used in the packaging process of items shall be free of asbestos and asbestiform-like materials.

10. Marking
10.1 Each water trap shall bear a weathertight tag showing the purchase order number, ASTM designation, size, and name of manufacturer. The markings on the package shall be approximately 25.4 mm (1 in.) high.

11.1 Source Inspection—The purchaser reserves the right to inspect the manufacturing process and end product in the supplier’s plant.

12. Keywords
12.1 diesel exhaust systems; piping systems
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract order.

S1. Provisions to withstand high shock. The grade will be specified by the navy requirements.

S1.1 When specified, the diesel exhaust water trap shall meet the requirements set forth in MIL-S-901.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Specification for
Mechanically Refrigerated Shipboard Air Conditioner

This standard is issued under the fixed designation F 1433; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers self-contained mechanically refrigerated air conditioners for shipboard use in air circulation, air cooling, and dehumidification.

1.2 These air conditioners are intended for use in compartments and areas where central system air conditioning is not provided.

1.3 The values stated in SI metric units are to be regarded as standard.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

3.2.1 air discharge plenum—an enclosure (housing) containing guide vanes and a grill or louvers in the outlet opening for directing the airflow.

3.2.2 air handling/evaporator section—an enclosed component consisting of an air filter, fan with drive motor, evaporator (cooling coil), refrigerant flow control, and condensate collector and drain.

3.2.3 condensing unit—contains refrigerating components, consisting of a compressor with a drive motor, condenser, receiver, operating and safety controls, and interconnecting piping and wiring. The controls include a condenser water regulating valve, high and low refrigerant pressure switches, refrigerant relief device, and motor overload protection.

3.2.4 cooling effect—the net room sensible cooling effect of a unit is defined as the difference between the net total cooling effect and the dehumidifying effect, expressed in watts. The net total cooling effect is the total useful capacity of the unit for removing heat from the space to be treated, expressed in watts. The net dehumidifying effect is the difference between the moisture content in kilograms per hour of the entering and leaving air, multiplied by 685, expressed in watts.

4. Classification

4.1 The air conditioners should be of the following types, services, arrangements, and size as specified:

- Type I drip-proof protected
- Type II explosion-proof enclosed
- Service 1 440-V 60-Hz alternating current (ac)
- Service 2 230-V direct current (dc)
- Service 3 115-V dc
- Service 4 220-V 60-Hz alternating current (ac)
- Arrangement A with air discharge plenum
- Arrangement B without air discharge plenum
- Size 2 minimum cooling capacity 7000 W
- Size 3 minimum cooling capacity 10 500 W
- Size 5 minimum cooling capacity 17 500 W
- Size 7½ minimum cooling capacity 26 000 W

5. Ordering Information

5.1 Orders for material under this specification shall include the following:

5.1.1 Title, number, and year of issue of this specification.
5.1.2 Type, service, arrangement, and size of unit (see 4.1).
5.1.3 Air discharge plenum required (see 6.1 and 6.5.10).
5.1.4 Type of power supply for equipment and motors (see 6.5.14.1 and 6.5.14.2).
5.1.5 When drip-proof protected or explosion-proof equipment is required (see 4.1, 6.5.14.1, and 6.5.14.2).
5.1.6 When certification and test reports are required (see 14.1).

6. Materials and Manufacture

6.1 General—Air conditioners covered by this specification shall consist of a condensing unit section, an air handling/evaporator section, and a motor controller. An air discharge plenum may be included, if specified. These air conditioners shall be self-contained and shall perform as specified in this specification when connected to cooling water, drainage, and electric power in accordance with UL 465 and ARI 210. The refrigerant system shall be constructed in accordance with the requirement of ASHRAE 15. Every component, including interconnecting wiring and piping, shall be enclosed within the cabinet, except where external mounting is permitted by this specification. The air conditioner shall be factory assembled, complete, self-contained, with the refrigerant system and components dehydrated and charged with the operating quantities of refrigerant and oil. The air conditioner shall be ready for operation after removal of the shipping protection, opening of valves, adjustment of belts, and connection to services. Valves, controls, and equipment subject to service and repair shall be readily accessible for servicing through removable panels. Where panels are provided for access to equipment, machine screws may be used for fastening.

6.2 Refrigerant System—Every component, including piping, controls, and accessories by the refrigerant system, shall be constructed for use with Refrigerant-22 (monochlorodifluoromethane) or other specified refrigerant.

6.3 Materials—Materials shall be as specified in this specification.

6.3.1 Dangerous Materials—Mercury and materials which may produce dangerous gases or cause other harmful effects under conditions, including fire, shall not be used. Magnesium and its alloys shall not be used in the manufacture of the air conditioners or in any component parts.

6.3.2 Corrosion Protection—Corrosion-resisting steel, copper, brass, bronze, chromium, copper-nickel, and copper-nickel alloys as specified in this specification are considered corrosion-resisting materials. Where corrosion-resisting steel is used, it shall be type 316 or 347 in accordance with Specification A 276. Corrosion-resisting steel, when fabricated by any method that tends to reduce corrosion-resisting properties, shall be normalized to restore those properties before being used in the assembly of any unit.

6.3.2.1 Noncorrosion-Resisting Materials—Noncorrosion-resisting materials are to be protected against corrosion by the use of the chemicals, electrolytic processes, plating, or paints and enamels.

6.3.2.2 Fastenings or Fittings—Bolts, nuts, studs, pins, screws, and such other fastenings or fittings shall be of corrosion-resisting material. Self-tapping screws with machine screw threads may be used in the cabinet assembly. Sheet metal screws with sheet metal threads shall not be permitted.

6.3.3 Galvanic Corrosion—Direct contact of electrolytically dissimilar materials shall be avoided to prevent galvanic corrosion.

6.4 Piping System—The construction of the piping system shall include inlet and outlet Schedule 40 copper-nickel condenser water piping of the proper diameter, extending horizontally outside of the air conditioner cabinet. Construction shall also include the proper size and type of drain piping from the drain connection of the air conditioner through the cabinet down to the deck level.

6.5 Air Conditioner Components:

6.5.1 Compressor—The compressor shall be of the hermetic type for service 1 and service 4 air conditioners and of the open type for service 2 and service 3 air conditioners. Provision shall
be made for adequate lubrication of the rubbing and wearing surfaces, including operation under ship motion, as specified in 7.3. Compressors shall be provided with a crankcase heater. Crankcase heaters shall be replaceable without having to remove oil or refrigerant from the compressor and shall be arranged to provide compressor oil heating before start-up and at any time the compressor is in the off cycle. Compressors shall be provided with suction and discharge compressor service shutoff valves and means for charging.

6.5.1.1 Open Compressor—The open compressor shall be of the positive displacement type. The shaft seal and main bearings shall be replaceable in their entirety without the necessity of replacing or refurbishing the crankshaft or crankcase. Compressor speeds for open compressors shall not exceed 1800 revolutions per minute (t/min).

6.5.1.2 Hermetic Compressor—The hermetic compressor shall be of the positive displacement type.

6.5.2 Condenser—The condenser shall be seawater cooled and constructed in accordance with the criteria shown in Table 1. The condenser shall be sized so that the compressor motor shall not be overloaded when the air conditioner is experiencing overload conditions. The condenser shall be a shell and tube construction with water in the tubes and refrigerant in the shell and shall have an even number of water passes. The condenser shall be mechanically cleanable in place with removable water boxes or heads to permit tubes to be examined, cleaned, or replaced as necessary. The condenser shall be cleanable from either side of the cabinet. Means shall be provided to remove entrained air from each inlet pass. Condenser heat drains shall be provided. Zinc anodes shall be provided in the condenser heads (seawater side). The condenser shall be removable water boxes or heads to permit tubes to be examined, cleaned, or replaced as necessary. The condenser shall be cleanable from either side of the cabinet. Means shall be provided to remove entrained air from each inlet pass. Condenser heat drains shall be provided. Zinc anodes shall be installed in the condenser heads (seawater side). The condenser shall have a means for purging air and noncondensable gases and a relief valve to prevent overpressurization of the refrigerant side. The tube sheets shall be of copper-nickel (90-10) UNS C70600. The condenser heads shall be of valve bronze, Specification B 61, or nickel-aluminum-bronze, Specification UNS C70600. The tubes shall be 19-mm outside diameter, constructed of copper-nickel (90-10) UNS C70600. The tubes shall be extruded fin type. Drain and vent fittings and zinc anode holders shall be nickel-copper (70-30) UNS C71500.

6.5.3 Liquid Receiver—The liquid receiver shall have an internal volume at least 25 % greater than the volume of the complete refrigerant charge. The receiver shall contain an outlet shutoff valve and pressure relief device.

6.5.4 Cooling Coil—The cooling coil (evaporator) shall be of finned-tube construction and shall be composed of copper tubes, in accordance with Specification B 75, or aluminum tubes with copper fins. Fins shall be firmly bonded to the tube. A drip pan and drain for collecting the condensate shall be furnished.

6.5.5 Water-Regulating Valves—A water-regulating valve shall be provided at the outlet to each condenser. The valve shall be direct-acting or pilot-controlled actuated by condenser gas pressure to modulate the flow of water required for the condenser. The valve shall withstand seawater inlet pressures up to 1.37 MPa. The valve shall be constructed of nonferrous or corrosion-resisting material. The valve shall be constructed to prevent the entry of seawater into the refrigerant system in the event of derangement.

6.5.6 Strainer—A strainer shall protect the condenser and water-regulating valve. The strainer shall be not less than 19 mm n.p.s. However, it shall be sized as to not restrict seawater flow during overload conditions. The strainer shall be shipped loose for installation in the seawater piping during air conditioner installation.

6.5.7 Expansion Valve—Refrigerant flow to the cooling coil (evaporator) shall be controlled by a thermostatic valve. The valve shall be an adjustable superheat, externally equalized type. The valve body shall be of cast or forged brass or bronze, and the inlet and outlet connections shall be an integral part of the valve body.

6.5.8 Piping—Any piping necessary for the operation of the equipment shall be provided up to and including fittings at each unit required for interconnection to supplementary service. Exterior connection fittings shall be capped or plugged to safeguard against damage before installation. The water regulating valve shall be installed in the condenser water discharge line and shall be readily accessible for adjustment and maintenance. Condenser water supply piping and drain piping shall be copper-nickel alloy 706. Water pipe fittings and seawater connections shall be 90-10 copper-nickel, valve bronze in accordance with Specification B 61 or monel. No tapered pipe threads shall be used anywhere in the unit. Refrigerant piping shall have readily accessible test fittings for high and low pressure and for charging and draining refrigerant. Refrigerant pipe fittings shall be in accordance with Specification B 16/B 16M. Refrigerant piping and evaporator condensate drain tube shall be copper in accordance with Specification B 75, alloy 12200.

6.5.8.1 Disposable Dehydrator—A disposable dehydrator shall be provided in the refrigerant circuit. The dehydrator shall be equipped with an auxiliary screen or other protective means at the dehydrator outlet to prevent passage of the dehydrating
shall be replaceable, without removal of the blower, from the accordance with Federal Specification FF-B-171. Bearings shall be replaceable permanently lubricated ball bearing type in supported by not less than two self-aligning bearings. Bearings quiet in operation. They shall be secured to shafts and shall be mission of noise generated by the air conditioner to surround-
cabinet.

protection of the plenum shall be identical to that for the air flow in both horizontal and vertical planes. Corrosion air flow. The outlet louvers shall permit adjustable directional structuring to mount on top of the cabinet. The plenum shall outlets shall be interconnected to a common drain tube.

condensate under conditions as specified in 7.4. The drip pan have depth and baffles and multiple drain outlets to prevent condensate from the cooling coil (evaporator). The pan shall be constructed for front air intake and top air discharge. The air intake shall be provided with a protective grill. The front of the machinery compartment shall be provided with a removable panel for servicing the equipment. The back of the machinery compartment shall be enclosed with an expanded metal screen for service 2 and service 3 air conditioners. After fabrication, the cabinet shall be galvanized or coated with one coat of metal primer and enamel topcoat to protect from corrosion. Brackets or integral frame members shall be provided for mounting and fastening the air conditioner to a deck foundation.

Cabinet—The cabinet enclosure shall be constructed of steel or aluminum protected against corrosion. Aluminum shall be Specification B 209, alloy 5052, temper H-32¼ hard. Steel shall be low carbon steel, Specification A 569/A 569Mor equivalent. The cabinet shall incorporate framing, chassis, and support for any component of the air conditioner. The cabinet, framing, and chassis shall support and maintain proper alignment and arrangement of every component under the ship operational conditions as specified in 7.4. The air handling section of the cabinet shall be constructed for front air intake and top air discharge. The air intake shall be provided with a protective grill. The front of the machinery compartment shall be provided with a removable panel for servicing the equipment. The back of the machinery compartment shall be enclosed with an expanded metal screen for service 2 and service 3 air conditioners. After fabrication, the cabinet shall be galvanized or coated with one coat of metal primer and enamel topcoat to protect from corrosion. Brackets or integral frame members shall be provided for mounting and fastening the air conditioner to a deck foundation.

Drip Pan—A condensate drip pan shall collect condensate from the cooling coil (evaporator). The pan shall be constructed from corrosion-resistant material. The pan shall have depth and baffles and multiple drain outlets to prevent overflow of the condensate and provide for draining of the condensate under conditions as specified in 7.4. The drip pan outlets shall be interconnected to a common drain tube.

Plenum—An air discharge plenum shall be provided when specified. The plenum shall be detachable and constructed to mount on top of the cabinet. The plenum shall contain air guide vanes and louvers as required for directing the air flow. The outlet louvers shall permit adjustable directional air flow in both horizontal and vertical planes. Corrosion protection of the plenum shall be identical to that for the cabinet.

Insulation—Thermal insulation shall be applied as necessary to the cabinet, piping, and components to prevent sweating, dripping, running off, or blowing off of moisture. Acoustical insulation shall be applied to minimize the transmission of noise generated by the air conditioner to surrounding areas.

Fans—Fans shall be of the centrifugal type and be quiet in operation. They shall be secured to shafts and shall be supported by not less than two self-aligning bearings. Bearings shall be replaceable permanently lubricated ball bearing type in accordance with Federal Specification FF-B-171. Bearings shall be replaceable, without removal of the blower, from the front or sides of the unit after removal of the service panel.

6.5.13 Air Filter—Air filters shall be arranged to filter ventilation or recirculated air before it enters the evaporator. Filters shall be of the permanent washable type. Materials used in the construction of the filters shall be corrosion-resisting or aluminum. The air filters shall be arranged so they shall not come in contact with condensate from the cooling coils.

6.5.14 Electrical Equipment—The electrical equipment shall be in accordance with NEMA MG 1 and NEMA ICS 1 and shall operate in a 50°C ambient temperature. No portion of the electrical circuit shall be grounded. The frames or enclosures of all electrical components shall be grounded to the frame of the air conditioning unit to eliminate hazard from shorts or grounds within the equipment. The air conditioner shall be provided with a motor controller for remote mounting. Electrical equipment for Type II air conditioners shall meet the requirements of Code of Federal Regulations, Title 46, Subchapter J, Subpart 111.105.

6.5.14.1 Motors—Motors shall be constant speed, continuous duty, with a maximum speed of 3600 r/min, and shall be for the power supply specified. The temperature rise of motors in accordance with NEMA MG 1 shall not exceed 21°C and they shall be provided with built-in thermal protectors installed in accordance with NEMA MG 1. The motors shall be drip-proof or explosion-proof enclosed. Motors shall start the compressor with the maximum refrigerant pressure differential.

6.5.14.2 Motor Controls—Enclosure of the compressor and fan motor controllers shall be one of the following types, as specified,

(1) Drip-proof (45°), watertight, submersible (4.5 m).
(2) Explosion-proof.
(3) Splash-proof.

For hermetic units, overload relays shall be in addition to, and coordinated with, thermal protectors built into the motor. Fans shall be protected with an overload relay or built-in thermal protector. The compressor shall not start or run unless the fan is operating and the compressor shall stop if the fan motor circuit is interrupted. A time delay circuit shall be provided to prevent restarting of the compressor manually or automatically within 5 min of having been stopped for any reason. Delay shall not preclude initial starting of the air conditioner.

6.5.14.3 Controls—A selector switch shall permit operation of the fan only, or of the fan and refrigerating equipment. High pressure and low pressure safety switches and a temperature control shall be provided. The selector switch shall be of a three-position type with an off position to secure both the fan and refrigerating equipment. The temperature control shall provide for automatic compressor control. It shall provide for manual adjustment and operate within a temperature range of 18 to 29°C, with a plus or minus 3°C tolerance. The selector switch shall be readily accessible. The temperature control shall be located within the machinery compartment. The unit shall have separate pressure switches properly set to stop the compressor when the refrigerant discharge pressure rises too high, or suction pressure becomes too low. The pressure controls shall be individual units of the lock open, manual reset type. Pressure and temperature controls shall be in accordance with UL 873. A terminal block or blocks shall be provided with the remote motor controller enclosure for the interconnection.
of all electrical circuits. The internal wiring within the air conditioner cabinet shall be completed to an enclosure containing the necessary terminal blocks, within the cabinet, for interconnection to the motor controller enclosure. Control switches or other electrical devices located external to the motor controller enclosure shall not have protruding or unprotected electrical connection lugs or terminals. Control switches requiring mechanical adjustment shall not be located within the motor controller enclosure unless provision is made so that the necessary adjustments can be made without removing the enclosure cover. When these control switches are located within the air conditioner cabinet, they shall be mounted directly or indirectly, by means of mounting brackets or mounting plates, to the cabinet structure to minimize the effect of vibration from the rotating machinery. They shall be located to minimize the possibility of personnel coming in contact with live electrical parts when servicing the controls.

7. Performance Requirements

7.1 Operation—Operation shall automatically maintain the environmental conditions for which the equipment is set as specified in Table 1.

7.2 Air-Circulating Equipment—The unit shall have the capacity for circulating air through the air conditioning unit at not less than 0.7 m³/min per 290 W of cooling capacity.

7.3 Ship Inclination—The air conditioner shall operate on a surface ship while withstanding 15° permanent, or 45° cyclic, inclination.

7.4 Capacity—Air conditioner shall deliver not less than its specified capacity when operating at the rating conditions as shown in Table 1. The net capacity shall be exclusive of all electrical energy (heat energy) required to operate the compressor, fan, and other units. The air flow quantity shall be at least that specified in Table 1.

7.5 Overload—The temperature rise for motors shall not exceed 70°C for motors in accordance with NEMA MG 1.

7.6 Condensation—The air conditioner shall operate without dripping, running, or blow off of moisture either inside or outside the cabinet.

8. Other Requirements

8.1 Manuals—Manuals shall be prepared in accordance with the manufacturer’s commercial practice. Photo views of the equipment shall be included as part of the general description. A section shall be included containing reduced copies of all drawings required to amplify or illustrate the text, including diagram and assembly drawings. The manual shall contain a parts list and all data necessary to install, operate, repair, and maintain the equipment.

9. Dimensions

9.1 Maximum dimensions of the air conditioner cabinets, including mounting brackets and plenums, shall be as shown in Table 2.

10. Sampling

10.1 When first article inspection is specified, the first air conditioner of each type, service, and size produced under the contract or order shall be selected for testing.

11.1 Responsibility for Inspection—Unless otherwise specified in the contract or purchase order, the contractor is responsible for the performance of all inspection requirements (examinations and tests) as specified in this specification. Except as otherwise specified in the contract or purchase order, the contractor may use his own or any other facilities suitable for the performance of the inspection requirements specified in this specification. The purchaser reserves the right to perform any of the inspections set forth in the specification where such inspections are deemed necessary to assure supplies and services conform to prescribed requirements.

11.2 Responsibility for Compliance—All items shall meet all specification requirements. The absence of any inspection requirements in the specification shall not relieve the contractor of the responsibility of assuring that all products or supplies submitted comply with all requirements of the contract. Sampling inspection, as part of the manufacturing operations, is an acceptable practice to ascertain conformance to requirements, however this does not authorize submission of known defective material, either indicated or actual.

12. Test Methods

12.1 Classification of Inspections—The inspection requirements specified in this specification are classified as follows:

1. First article inspection (see 12.2)
2. Quality conformance inspection (see 12.3)

12.2 First Article Inspection—When specified in the contract or purchase order, first article inspection shall consist of the tests and examinations as specified in 12.4 and 12.5-12.5.4.3.

12.3 Quality Conformance Inspection—Quality conformance inspection of each air conditioner shall consist of the tests and examinations as specified in 12.4 and 12.6-12.6.2.

12.4 Visual Examination—Each sample unit shall be examined for adjustments, fits, leaks, material, finish, and general conformance to this specification as follows:

1. The external fittings shall be properly secured.
2. Bolts, nuts, and screws shall be tight; equipment and parts shall be properly fastened and secured.
3. No parts shall be fractured, split, torn, dented, or otherwise damaged such as to affect serviceability.
4. There shall be no sharp or ragged edges on the sheeting that may be injurious to personnel.
5. Cold lines shall be properly insulated.
(6) The limiting and mounting dimensions shall be in accordance with drawings and Table 2.

(7) The temperature control shall be properly set and functioning.

(8) The selector switch shall operate satisfactorily.

(9) There shall not be any dripping, running, or blowing off of moisture.

(10) The low pressure and high pressure switch shall be functioning and properly set in accordance with the manufacturer’s specification.

(11) There shall be no refrigerant leakage at any brazed, welded, or mechanical joint as measured using an electronic halide leak detector adjusted to detect a leak of 14 g per year.

12.5 First Article Test Procedures:

12.5.1 General—Before testing, the air conditioner shall have successfully passed the visual examination specified in 12.4. For first article tests, fresh water may be used in lieu of seawater for cooling.

12.5.2 Inclination—The unit shall be inclined at an angle of 15° each side of the vertical in each of two vertical planes at right angles to each other and operated at least 1 h or cycled at 45° for 1 h, under applied rating conditions as specified in Table 1. Test information shall be monitored at 10-min intervals throughout the test. The unit shall be acceptable if there is no spillage of fluids inside or outside the cabinet, no abnormal noise, and no loss of capacity.

12.5.3 Capacity Rating—Capacity rating tests shall be conducted in accordance with the procedures and requirements indicated in ASHRAE 37 and ARI 210. A standard rating test shall be conducted using standard rating conditions in accordance with ARI 210. An application rating test shall be conducted using the operating conditions as shown in Table 1.

12.5.4 Performance—The unit to be tested shall be given the continuous operating tests as specified in 12.5.4.1-12.5.4.3 under the average temperature conditions as indicated with a tolerance of ±0.5°C dry bulb, ± wet bulb, and ± condenser water temperature. Observations and readings shall be taken at intervals not greater than 10 min.

12.5.4.1 Overload—The unit shall be operated with 38°C dry bulb temperature, 30°C wet bulb temperature unit-ambient-air and room air entering-air-inlet, and 38°C water to the condenser. The test shall be continued until steady conditions have been observed for not less than 4 h. The unit shall operate normally without any interruption caused by tripping of motor-overload devices, without damage to motors as a result of overheating, and without injury to any other component part from any operational cause. The temperature rise of the compressor motor winding shall be determined at the end of this test. The temperature rise shall not be greater than that as specified in 6.5.14.1. The temperature rise of the windings shall be measured and computed by the resistance method. In addition, the air conditioner shall be tested to determine actual capacity under overload conditions as shown in Table 1.

12.5.4.2 Condensation—The unit shall be operated continuously for 4 h with 35°C condenser inlet water, 27°C dry bulb temperature, and 24°C wet bulb temperature unit-ambient-air and room air entering-air-inlet. The air conditioning unit shall perform satisfactorily during the test without dripping, running, or blowing off of moisture either inside or outside the cabinet.

12.5.4.3 Air Delivery—The unit shall be provided with a means of restricting the outlet air to produce the minimum outlet resistance as specified in Table 1. The air flow quantity shall be not less than that specified in Table 1.

12.6 Operating Tests—Each air conditioner shall be operated for a period of at least 1 h with controls set to allow continuous compressor operation as shown in Table 1. During this test, inlet air temperature to the evaporator shall be not less than 24°C dry bulb. At the conclusion of this operation test, the entire refrigerant circuit connections under refrigerant pressure shall be tested to determine leakage. In the event of leakage, the leaks shall be repaired and the operating test shall be repeated.

12.6.1 Controls—During this test it shall be verified that the controls are adjusted and functioning properly.

12.6.2 Electrical Power—The electrical power input shall be recorded during operating tests and compared with the input of all other units which have been tested. If any unit requires 7% more power than the average of all the acceptable units, it shall be rejected.

13. Rejection and Rehearing

13.1 Test Failure—Failure of the first article air conditioner to pass any of the tests or examinations specified in this specification shall constitute rejection of the air conditioner design. The resumption of tests and examinations will be considered by the contracting activity after receipt of information substantiating that the deficiencies found have been corrected satisfactorily.

13.2 Acceptance Criteria—Production units failing to meet the tests specified in 12.6-12.6.2 shall be repaired, defective parts and components replaced, and retested until specification requirements are met before offering the air conditioner for acceptance.

14. Certification

14.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

15. Product Marking

15.1 Identification plates shall be made of brass, aluminum, or corrosion-resisting steel. Information plates shall be made of laminated plastic, aluminum, or corrosion-resisting steel. The identification plate shall be located in the front of the machinery compartment. Identification plates shall be secured to equipment with electrolytically compatible fasteners and shall contain the following information:

(1) Name of equipment: Air conditioner,
(2) Manufacturer’s name and address,
(3) Manufacturer’s model, type, capacity,
(4) Manufacturer’s serial number,
(5) Date of manufacture,
(6) Contract or purchase order number, and
(7) Specification number and appropriate type, service, class, size (cooling capacity), and power supply.

15.2 A warning plate shall be mounted on the motor controller enclosure with the following engraving in red letters:

“WARNING: DANGER HIGH VOLTAGE”

15.3 In addition to the identification plate, equipment for explosion-proof applications shall have a warning plate. The warning plate shall be located on the front of the cabinet. Lettering shall be readily legible, reading as follows: “Caution: This Equipment is for Explosion-Proof Application. Disconnect Power Supply Before Opening Electrical Box Covers. Do Not Energize Unless the Equipment is Fully Assembled and All Electrical Enclosures are Properly Closed.”

16. Packaging and Package Marking

16.1 Packaging and package marking shall be in accordance with Practice D 3951.

16.2 For government packaging and package marking, see Supplementary Requirements.

17. Keywords

17.1 air conditioner; air discharge plenum; compressor; condensing unit; evaporator; liquid receiver; mechanically refrigerated

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements are applicable to Department of Defense procurements and shall apply only when specified in the contract or order.

S1. Referenced Documents

S1.1 ASTM Standards:² D 3951 Standard Practice for Commercial Packaging

S1.2 Federal Specifications:⁹ TT-P-664 Primer Coating, Alkyd, Corrosion-Inhibiting, Lead and Chromate Free, VOC Compliant

PPP-F-320 Fiberboard: Corrugated and Solid Sheet Stock (Container Grade) and Cut Shapes

S1.3 Military Specifications:⁹ MIL-P-116 Preservation, Methods of

MIL-L-19140 Lumber and Plywood, Fire- Retardant Treated

S1.4 Military Standards:⁹ MIL-STD-1186 Cushioning, Anchoring, Bracing, Blocking and Waterproofing; With Appropriate Test Methods

MIL-STD-2073-1 DoD Material Procedures for Development and Applications of Packaging Requirements

S2. Ordering Information

S2.1 Orders for equipment using this supplement shall include the following information in addition to the ordering information from the basic specification:

S2.1.1 Fire retardant material requirements (see S3.1.1).

S2.1.2 Preservation requirements (see S3.2).

S2.1.3 Packing requirements (see S3.3).

S2.1.4 Required waterproofing (see S3.3.5).

S2.1.5 Package marking requirements (see S3.4).

S3. Packaging

S3.1 Fire Retardant Requirements:

S3.1.1 Treated Lumber and Plywood—Unless otherwise specified, all lumber and plywood including laminated veneer material used in shipping containers and pallet construction, members, blocking, bracing, and reinforcing shall be fire retardant treated material conforming to MIL-L-19140 as follows:

<table>
<thead>
<tr>
<th>Levels A and B</th>
<th>Type II—weather resistant</th>
</tr>
</thead>
</table>
| Category 1—general use

S3.1.2 Fiberboard—Fiberboard used in the construction of class domestic, nonweather-resistant fiberboard, cleated fiberboard boxes, including interior packaging forms, shall meet the flame spread index and the specific optic density requirements of PPP-F-320 and amendments thereto.

S3.1.3 Cushioning and Wrapping Materials—The use of excelsior, newspaper, shredded paper (all types), and similar hygroscopic or nonneutral materials and all types of loose fill materials for packaging applications, such as cushioning, fill, stuffing, and dunnage is prohibited. Materials selected for cushioning and wrapping shall have properties (characteristics) for resistance to fire. Cushioning or wrapping materials, as applicable, shall be provided to prevent item and package damage and to prevent free movement of the container contents.

S3.2 Preservation—Preservation shall be level A or commercial as specified.

S3.2.1 Level A—Each complete unit shall be unit protected in accordance with Method I requirements of MIL-P-116 and as follows: exterior unpainted ferrous metal surfaces shall be coated with P-19 preservative in accordance with MIL-P-116. The water cooling system shall be thoroughly drained and blown out by the application of clean, dry compressed air. To prevent the entrance of foreign material, all openings shall be sealed with the use of metal or plastic plugs or waterproof pressure-sensitive tape. Drive belts shall be removed, exposed uncoated ferrous metal surfaces of pulleys and shafts shall be cleaned and coated with primer in accordance with TT-P-664. When the primer is thoroughly dry, drive belts shall be remounted in place with tension on the belts relaxed.

S3.2.2 Commercial—Commercial preservation shall be in accordance with Practice D 3951.

S3.3 Packing—Packing shall be Level A, B, C, or commercial as specified.
S3.3.1 General—Shipping containers shall contain identical quantities of identical material and shall be of minimum weight and cube, similar construction, and of uniform size.

S3.3.2 Level A, B, and C Containers—Material preserved as specified shall be packed in shipping containers, cleated plywood, or nailed and locked corner boxes or covered crates, for the level of packing specified, in accordance with MIL-STD-2073-1, Appendix C, Table 7. Unless otherwise specified, container selection shall be at the contractor’s option.

S3.3.3 Closure—Container closure, reinforcing, or banding shall be in accordance with the applicable container specification or appendix thereto except that class weather resistant fiberboard boxes shall be closed in accordance with MIL-STD-2073-1, Method V, and reinforced with nonmetallic or tape banding, and nonweather resistant fiberboard boxes shall be closed in accordance with Method I using pressure-sensitive tape.

S3.3.4 Weight—Wood, plywood, and cleated-type containers exceeding 90-kg gross weight shall be modified by the addition of skids in accordance with MIL-STD-2073-1 and the applicable container specification or appendix thereto.

S3.3.5 Waterproofing—Unless otherwise specified, level A and when specified, level B, shipping containers shall be provided with caseliners, linings, wraps, or shrouds in accordance with the waterproofing requirements of MIL-STD-1100.

S3.3.6 Commercial—Material preserved as specified shall be packed for shipment in accordance with Practice D 3951. Shipping containers exceeding 90-kg gross weight shall be provided with the minimum of 0.08 by 0.1-m nominal wood skids laid flat, or a skid- or sill-type base that will support the material and facilitate handling by mechanical handling equipment during shipment.

S3.4 Marking

S3.4.1 Level A, B, and C and Commercial Marking—In addition to any special marking required, level A, B, and C interior packs and shipping containers shall be marked in accordance with MIL-STD-2073-1, Appendix F, and commercial interior packs and shipping containers shall be marked in accordance with Practice D 3951. In addition, bar coding shall be applied in accordance with the marking requirements of MIL-STD-2073-1 and the shipment marking information shall be provided on interior packages and exterior shipping containers and shall include the following:

1. Nomenclature,
2. National stock number,
3. Manufacturer’s part number,
4. Size,
5. Contract or order number,
6. Contractor’s name, and
7. Destination.

S3.5 Technical Manuals—Technical manuals that accompany shipment shall be packaged in a transparent waterproof plastic bag, minimum 4 mil thick. Closure shall be by heat sealing. The copy(s) of the manual shall be placed in the shipping container housing the main unit. Packing lists shall indicate which container contains the technical manual(s) and shall state the approximate location therein. The manual shall be readily accessible when the container is opened. Technical manuals, when shipped in bulk quantities, shall not be individually wrapped, but shall be packed in accordance with the requirements of the applicable technical manual specifications.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Practice for Inclined Cargo Tank Ladders

This standard is issued under the fixed designation F 1437; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice provides design, construction, and installation criteria for inclined ladders to be installed within cargo tanks.

1.2 Where ladders are attached to platforms, see Fig. 1 and Fig. 2.

1.3 Values stated in SI units are to be regarded as the standard. The values stated in parentheses are provided for information purposes only.

2. Referenced Documents

2.1 ASTM Standards:
A 36/A 36M Specification for Structural Steel

2.2 Other Documents:
American Bureau of Shipping Rules for Building and Classing Steel Vessels
American Welding Society Publication, AWS D 1.1 Structural Welding Code—Steel
SAE AMS-C-27725 Coatings, Corrosion Preventative, Polyurethane, for Aircraft Integral Fuel Tanks for Use to 250 Degrees F (121 Degrees C)
Steel Structures Painting Council Specification

3. Classification

3.1 Ladders shall be classified into two types:

3.1.1 Type I—Ladders installed within cargo tanks carrying cargo other than fuel oil, and

3.1.2 Type II—Ladders installed within cargo tanks carrying fuel oil.

4. Significance and Use

4.1 This practice establishes the procedure for the construction and installation of inclined ladders to be fabricated and installed, by the shipyards, within the cargo tanks.

5. Materials and Manufacture

5.1 Materials—(Type I):
5.1.1 Stringers—230-mm (approximately 9-in.) by 50-mm (approximately 1 ¾-in.) structural channels of carbon steel. (See Specification A 36/A 36M.)

5.1.2 Upper and Lower Clips—Flat bars of carbon steel. (See Specification A 36/A 36M.)

5.1.3 Handrails and Stanchions—25 mm (approximately 1 in.) diameter carbon steel. (See Specification A 36/A 36M.)

5.1.4 Treads—75-mm (approximately 3-in.) by 10-mm (approximately ¾-in.) structural angles of carbon steel. (See Specification A 36/A 36M.)

5.2 Materials—(Type II):
5.2.1 Stringers—Structural flat bars of carbon steel. (See Specification A 36/A 36M.)

5.2.2 Upper and Lower Clips—Flat bars of carbon steel. (See Specification A 36/A 36M.)

5.2.3 Treads—25-mm (approximately 1-in.) by 25-mm square bars of carbon steel. (See Specification A 36/A 36M.)

5.3 Manufacture:
5.3.1 All welding shall be in accordance with American Bureau Shipping Rules for Building and Classing Steel Vessels or AWS D 1.1.

6. Dimensions

6.1 Dimensions indicated are typical. However, these dimensions can be changed to suit other existing structures.

6.2 The tread lengths, or the clear widths, between the stringers for Type I ladders, for commercial and naval ships, shall be 455 mm (approximately 18 in.) and 610 mm (approximately 24 in.), respectively.

6.3 The tread lengths or clear widths between stringers for Type II ladders shall be 380 mm (approximately 15 in.).

6.4 The lengths of the ladder shall be fabricated to suit existing requirements.

6.5 Tolerance shall be ±6 mm (approximately ¼ in.).
6.6 Type I ladders shall have the following dimensions: installed angle: 50 to 69° from the horizontal; tread depth: 175 to 250 mm (approximately 7 to 10 in.) at 50°, tapering to 75 mm (approximately 3 in.) at 69°; riser height 175 to 300 mm (approximately 7 to 12 in.); handrail 25 to 31 mm (1 to 1 1/4 in.) in diameter.

6.7 Type I ladder tread surfaces shall have slip-resistant surfaces of a material compatible with materials to be carried in that tank.

6.8 Type II ladders shall be as follows: installed angle 70 to 90° from the horizontal; treads shall be equally spaced at a maximum of 305 mm (approximately 12 in.); the distance from the top tread to the upper walking surface is to be approximately equal to the normal tread spacing; and the distance from the bottom tread to the lower walking surface is not to exceed 375 mm (approximately 15 in.).

7. Workmanship, Finish, and Appearance

7.1 Ladders shall be free of all sharp edges, burrs, projections, weld splatter, and other defects which might be injurious to personnel or equipment or both.

7.2 For cargo tanks carrying cargo other than fuel oils, coat the ladders with one coat 3.0-mil dry film thickness inorganic zinc silicate following surface preparation in accordance with the Steel Structures Painting Council specifications or manufacturers paint instructions.
7.3 For spaces carrying fuel oil cargo, one coat of 3.0-mil dry film thickness of corrosion preventive coating shall be applied to the ladders in accordance with SAE-AMS-C-27725.

7.4 Connections between ladders and mounting clips may be bolted in lieu of the welding shown.

8. Keywords

8.1 cargo tank access; cargo tank ladders; inclined ladders; ladders
Standard Guide for
Selection of Structural Details for Ship Construction

This standard is issued under the fixed designation F 1455; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

The principal aim of this guide is to depict recommended practices related to the design of ship structural details. The importance of structural details is clear:

1) Their layout and fabrication represent a sizable fraction of hull construction costs.

2) Details are often the source of cracks and other failures which, under certain circumstances, could lead to serious damage to the ship hull girder.

3) The trend toward decreasing ship hull scantlings (that is, increasing average hull stresses) has the potential of increasing the damage to details.

4) Researchers have largely neglected the analysis of structural details at least in part because the configuration and purpose of these details vary greatly and are not commonly described or discussed in the literature.

Due to lack of analytical and experimental effort devoted to structural details, their determination has been left up to draftsmen and designers, with very little engineering input.

In two comprehensive reviews\(^2\,^3\) of the performance of structural details, 86 ships were surveyed. These included naval and commercial ship types. The commercial ships included both U.S. and foreign built. The vessels ranged from 428 to 847 feet in length, from 18,000 to 90,000 tons in displacement, and from five to twenty-six years in age. The details obtained were grouped into 12 typical families. Knife Edge Crossings (Family No. 6) and Structural Deck Cutout Details (Family No. 9) are shown but not covered in detail in this guide. The remaining ten detail families were further categorized into 53 groups comprising a total of 611 detail configurations. A number of these configurations are very similar to others in detail geometry and such duplicates have been excluded from this guide. A number of others were eliminated because of relatively infrequent observed use. As a result, a total of 414 details are included herein. However, all 611 details can be found in “Structural Details,”\(^4\) if desired.

In total, 607,584 details were observed with a total of 6,856 failures. Failures were attributed to one or a combination of five categories: design, fabrication, welding, maintenance, and operation (see 4.1 through 4.5). This extensive, well documented research, together with engineering judgement, provides the principal support for this guide.

1. Scope

1.1 This guide provides a recommended list of selected ship structure details for use in ship construction.

1.2 Structural details which have failed in service and are not recommended for use in ship construction are included as well.

1.3 This guide is intended to convey the lessons learned on different configurations of ship structure details, not the dimensions, thickness, or construction methods which would result from structural calculations.\(^4\)

2. Terminology

2.1 Definitions of Terms Specific to This Standard:

2.1.1 Terms:

2.1.2 beam bracket—a bracket at the end of framing or stiffening members that is used for increased strength, continuity and end constraint.

\(^1\) This practice is under the jurisdiction of ASTM Committee F25 on Shipbuilding and is the direct responsibility of Subcommittee F25.01 on Structures.

2.1.2.1 Discussion—see Fig. 1.

2.1.3 clearance cut-outs—a hole or opening in a pierced member to allow passage of a piercing member.

2.1.3.1 Discussion—see Fig. 2.

2.1.4 gunwale connection—the connection of the sheer strake to the stringer strake of the uppermost deck of the hull.

2.1.4.1 Discussion—see Fig. 3.

2.1.5 knife edge crossing—the projected point intersection of members (plate members, stiffeners or bulkheads) on opposite sides of an intervening plate member. An undesirable condition to be avoided.

2.1.5.1 Discussion—Included for information only, see 3.1.

2.1.5.2 Discussion—see Fig. 4.

2.1.6 miscellaneous cut-out—small holes or openings of a variety of sizes and shapes used for access, drainage, ease of fabrication, stress relief, and so forth.

2.1.6.1 Discussion—see Fig. 5.

2.1.7 non-tight collar—a fitting at the cut-outs in way of the intersection of two continuous members that provides lateral support for the piercing member which does not fully fill the cut-out area of the pierced member. May be a lug.

2.1.7.1 Discussion—see Fig. 6.

2.1.8 panel stiffeners—intercostal, non-load-carrying members used to reduce the size of plate panels.

2.1.8.1 Discussion—see Fig. 7.

2.1.9 stanchion ends—structural fittings at the ends (top and bottom) of a stanchion to transfer loads from the supported member to the supporting member.

2.1.9.1 Discussion—see Fig. 8.

2.1.10 stiffener ends—the configuration of the end of an unbracketed, non-continuous stiffener.

2.1.10.1 Discussion—see Fig. 9.

2.1.11 structural deck cuts—allow passage through decks for access, tank cleaning, piping, cable, and so forth.

2.1.11.1 Discussion—Included for information only, see 3.1.

2.1.11.2 Discussion—see Fig. 10.

2.1.12 tight collar—as per non-tight collar but the cut-out in the pierced member is fully filled and is air-, oil-, or watertight as required. Tight collars may be lapped or flush fitted.

2.1.12.1 Discussion—see Fig. 11.

2.1.13 tripping bracket—a bracket or chock that provides lateral support to framing and stiffening members. Support may be provided to either the web or the flange, or to both.

2.1.13.1 Discussion—see Fig. 12.

2.2 Symbols:

2.2.1 Symbols are as indicated in Fig. 13. The detail identification symbol (Fig. 13, 1-J-1 for example) is the same as that assigned in the original research reports and is retained throughout for all details for ease in referring back to the reports if desired.

3. Summary of Guide

3.1 In this guide, details are shown for the ten families of structural details identified above and as shown in Fig. 1–3, 5–9, 11 and 12. Knife Edge Crossings, Fig. 4, are not discussed further in this guide since none were observed in the research and fortunately so. This detail represents very undesirable structural conditions and is to be avoided. Structural Deck Cuts, Fig. 10, are not discussed in this guide since this detail
must be considered in relation to the size of the opening and its proximity to primary structures.

3.2 Evaluation of details shown in Figs. 14-28 is based on in-service experience as described in “Design Guide for Structural Details”. Data for over 400 details is summarized and rated in the figures by observed relative successful performance. Each of the ten families of details include configurations with no signs of failures. The details without failures within each family group are shown in descending order of numbers observed. Those details with failures are shown in ascending order of failures (percentage are indicated for each). Thus the first detail shown in each family group has the best observed service performance and is most highly recommended while the last has the highest failure rate and therefore least desirable.

3.3 These details, rated as indicated above, provide guidance in the selection of structural detail configurations in future design and repair of such details.

4. Failure Causes

4.1 Failures in the details shown in Figs. 14-28 were attributed to either one or a combination of five categories: design, fabrication, welding, maintenance, and operation.

4.1.1 Design

4.1.1.1 Design failures generally resulted from the omission of engineering principles and resulted in a buckled plate or flange; the formation of a crack in a plate, flange or web; or the rupture of the bulkhead, deck or shell. Each of the families, with the exception of tight collars, had detail failures attributed to design.

4.1.1.2 Failures directly related to design in structural details and supporting members were the result of being sized without adequate consideration of applied forces and resulting deflections.

4.1.1.3 In the beam bracket configurations of family no. 1 (Fig. 14), 20% of the surveyed failures attributed to design were caused by instability of the plate bracket edge or by instability of the plate bracket panel. This elastic instability, which resulted from loads that produce critical compressive or shear stresses, or both, in unsupported panels of plating, can be eliminated when properly considered in the design process.

4.1.1.4 The failures of beam brackets by cracking occurred predominately where face plates had been sniped, at the welded connections, at the ends of the brackets, at cutouts in the brackets, and where the brackets were not properly backed up at hatch ends. The sniping of face plates on brackets prevents good transition of stress flow, creates hard spots and produces fatigue cracks due to the normally cyclic stresses of these members. Care must be taken to ensure proper transition with the addition of chocks, back-up structure, reinforcement of hole cuts, and the elimination of notches.

4.1.1.5 To reduce the potential for lamellar tearings and fatigue cracks in decks, bulkheads, and beams, transition brackets should be made continuous through the plating or supported by stiffeners rigid enough to transmit the loads.

4.1.1.6 The greater number of failures in the tripping bracket configurations of family no. 2 (Fig. 18), occurred at

hatch side girders, particularly in containerships. This will be a continuing problem unless the brackets are designed to carry the large lateral loads due to rolling when containers are stacked two to four high on the hatches. The brackets must, in turn, be supported by properly designed backing structure to transmit the loads to the basic ship structure.

4.1.1.7 Tripping brackets supported by panels of plating can be potential problems depending on the plate thickness. Brackets landing on thick plating in relationship to its own thickness may either buckle in the panel of the bracket, produce fatigue cracks along the toe of the weld, or cause lamellar tearing in the supporting plate. Brackets landing on plating with a thickness equal to, or less than its own thickness, may cause either fatigue cracks to develop or buckling of an unsupported panel of plating.

4.1.1.8 The non-tight collar configurations of family no. 3 (Fig. 21) experienced only a few failures. There are considerations, however, that must be used by the designer to ensure the continuation of this trend. The cutouts should be provided with smooth well rounded radii to reduce stress risers. Where collars are cut in high stress areas, suitable replacement material should be provided to eliminate the overstressing of the adjacent web plating. These considerations should reduce the incidents of plate buckling, fatigue cracking, and stress corrosion observed in this family.

4.1.1.9 For detail family no. 7, miscellaneous cutouts, (Fig. 24), the reasons for failure were as varied as the types of cutouts. Potential problems can be eliminated by the designer if, during detail design, proper consideration is given to the following:

1) Use generous radii on all cuts.
2) Use cuts of sufficient size to provide proper welding clearances.
3) Avoid locating holes in high tensile stress areas.
4) Avoid square corners and sharp notches.
5) Use adequate spacing between cuts.
6) Properly reinforce cuts in highly stressed areas.
7) Locate cuts on or as near the neutral axis as possible in beam structures.
8) Avoid cuts at the head or heel of a stanchion.
9) Plug or reinforce structural erection cuts when located in highly stressed areas.

4.1.1.10 The most damaging crack observed during the survey was in the upper box girder of a containership. This structure is part of the longitudinal strength structure of the ship in addition to being subjected to high local stresses due to the container loading in the upper deck. Openings in this structure must be located, reinforced, and analyzed for secondary bending stresses caused by high shear loads.

4.1.1.11 The clearance cutouts of family no. 8 (Fig. 20) are basically non-tight collars without the addition of the collar plate. Suggestions made for non-tight collars and miscellaneous cutouts are applicable for this family.

4.1.1.12 Well rounded corners with radii equivalent to 25% of the width perpendicular to the primary stress flows should be used. Special reinforcements in the form of tougher or higher strength steel, inserts, coamings, and combinations of the above should be used where fatigue and high stresses are a problem.

4.1.1.13 In general, failures in stanchion ends, family no. 10 (Fig. 25) were cracks which developed in or at the connection to the attachment structure. The addition of tension brackets, shear chocks, and the elimination of snipes would reduce the incidents of structural failure. All stanchion end connections should be capable of carrying the full load of the stanchion in tension or compression. Stanchions used for container stands or to support such structure as deckhouses on the upper deck should be attached to the deck with long tapered chocks to reduce stress flows from hull induced loads, and in no case should “V” notches be designed into such connections.

4.1.1.14 The stiffener ends in family no. 11 (Fig. 27) with webs or flanges sniped, or a combination of both, or square cut ends sustained failures. In nearly all cases, the failures occurred in the attached bulkhead plating, the web connection when the flange was sniped, or the shear clip used for square cut stiffener ends.

4.1.1.15 Stiffeners that support bulkheads subject to wave slap, such as exposed bulkheads on upper deck, or tank bulkheads, should not be sniped and suitable backing structure should be provided to transmit the end reaction of the stiffeners.

4.1.1.16 While snipping stiffeners ensures easier fabrication, any stiffeners subject to tank pressures or impact type loading
should be restrained at the ends and checked for flange stability to prevent lateral instability under load.

4.1.1.17 Panel stiffeners, family no. 12 (Fig. 28) while classified as not being direct load carrying members, should be designed for the anticipated service load. For instance, panel stiffeners on tank bulkheads, as with any other stiffeners subject to pressure head loads, should be treated the same as other local stiffening.
4.1.1.18 Panel stiffeners used as web stiffeners on deep girders should not be expected to restrain the free flange from buckling in the lateral direction unless they are designed as lateral supports.

4.1.1.19 The design of panel stiffeners should be the same as other local stiffeners with respect to cutouts, notches, and other structural irregularities.

4.1.2 Fabrication:
4.1.2.1 Unexpected stress concentrations produced cracks that initiated from structural cuts, details with poor alignment, and improperly worked materials. Fabrication techniques that ensure proper continuity of structural parts and eliminate
jagged edges and undercut welds would eliminate such failures. The failures caused by fabrication resulted from:

1) Poor cutting techniques (hand cutting or rough cutting with no follow-up dressing).
2) Failure to edge prep cutouts and plate edges after flame cutting.
3) Improper alignment of intercostal structures.
4) High residual stresses due to poor workmanship.

4.1.2.2 The following list should be considered during the fabrication process as an aid to reducing subsequent failures:

1) Consult with the designer before deviating from the design details.
2) Where hard spots, knife edge crossings, or improper tapers occur, consult with the designer to resolve the problem.
3) Avoid misaligned structure.
4) Properly dress the edge of all cuts.
5) Eliminate notches in any structure whether primary or secondary.
6) Only use heat for straightening when approved by design or fabrication documents.
7) Only use cold working in areas approved by design or fabrication documents and then only to the minimum extent possible.
8) Avoid improper edge distances that must be filled with weld.
9) Never leave erection cuts in the structure that are not on the detail plans or approved by the designer.
10) Don't use improper or defective materials.
11) Avoid leaving weld splatters, gouges or other imperfections.

4.1.3 Welding:

4.1.3.1 Cracks in structural welds developed in the heat affected zones, in the weld metal, and in the base metal where irregular weld configurations caused stress concentrations. Proper design and controlled welding procedures would ensure the quality of structural welds and reduce failures associated with welding.

4.1.3.2 Welding was identified as a cause of failure in many cases. Undersized welds, poor deposits or undercutting at the weld toe in areas of poor accessibility were the most common causes of weld failures. Other aspects of welding that are not easily recognized by visual inspection, but influence the formation of weld faults are:

1) Using the wrong type of electrode (this is especially true in ship structures where different material types are mixed).
2) Using the wrong heat input (either too high or too low for the electrode or filler metal being used).
3) Using an improper weld sequence that causes excessive distortion.
4) Using oversized welds by design, or to make up for poor fabrication.
5) Improper weld edge preparation on the plating or stiffener webs.
6) Improper weld cleaning before and between weld passes.
7) Improper back gouging in full penetration welds.

4.1.3.3 The weld and inspection requirements for primary structure is fully covered by the classification societies and the U.S. Navy. However, the requirements for secondary structure such as tripping stiffeners, panel stiffeners, miscellaneous openings and reinforcements are left to the designer’s judgment. Failures in these welds could lead to primary structure failures. Therefore, it is imperative during design and fabrication that requirements for proper welding be given full consideration. Every effort must be made to ensure that sufficient clearances are maintained, that cutouts are sufficiently sized for the welding required, and that all special applications are noted to ensure proper welding controls and weld contours. Access must be provided to allow the welder to reach in corners and behind flanges to ensure good weld contours, and avoid blobs, weld splatters, or weld arc strikes which could become the source of a crack.

4.1.3.4 If a weld is correctly sized, deposited, and inspected, the likelihood of a flaw or crack starting because of the weld is very remote.

4.1.4 Maintenance:

4.1.4.1 Failures were observed on ships that resulted directly from the lack of proper maintenance. Corrosion reduced...
the scantlings of the members below the design allowances with buckles developing from instability and cracks from
excessive stress. Ship owners and operators could eliminate structural failures from such causes if they maintained protective coatings on structures subjected to the corrosive action of the sea.

4.1.4.2 Throughout the design and fabrication process, every effort should be made to eliminate:
1) Areas that allow standing water.
2) Areas that are inaccessible.
3) Areas with ineffective coating materials.
4) Areas with improper location of miscellaneous cutouts.
5) Areas with high residual stresses.

4.1.4.3 Specific failures were attributed to maintenance. The following are suggested corrective measures for combating the cause of such failures:
1) Areas used for water ballast, or subject to casual water and/or salt spray should be coated with anti-corrosive coating.
2) Pockets and low spots should have drain holes, air holes and drain pipes to ensure that water does not stand or pocket on decks, behind structure or tanks. At the same time, the location of these openings should be judiciously considered to eliminate openings in high stress areas where possible and to reinforce those openings when they cannot be located out of those areas. This will reduce the effects of stress corrosion that lead to buckled plates and flanges, and the increase in stress that causes fatigue cracks.
3) Personnel access should be provided to all areas of the ship to afford the opportunity to conduct the necessary inspections and, where required, the preventive maintenance that will reduce costly repairs later.
4) Areas subjected to severe corrosion condition should be designed and fabricated to reduce areas of potential high stress which accelerate corrosion due to stress and fatigue.

4.1.5 Operations:
4.1.5.1 Details in the forward shell and forecastle areas of several ships sustained damage resulting from driving the ship at high speed in heavy weather. With the uncertainty of the slamming loads produced by such conditions, extreme care should be used in the selection, design, fabrication and
maintenance of all structural connections and details used in the forward area of the ship.

4.1.5.2 The majority of these failures were caused by operators trying to maintain a predetermined schedule based on a set course and speed. Other more obvious operations failure causes included cargo handling abuse, docking (drydocking as well as pier side operations), and minor collisions (including other ships, tugs and large floating objects).

4.1.5.3 The most prominent detail failures attributed to operations were to family no. 1 beam brackets, (Fig. 14). Of the beam bracket failures 67% were attributed to operation (heavy weather). Possible fixes for the beam brackets included the use of face plates or panel stiffeners to increase panel stability, the use of heavier plating to increase the corrosion margin and increase panel stability, and the elimination of the indiscriminate use of lighting holes and miscellaneous cutout in areas subject to potentially high operational loading.

4.1.5.4 Tripping brackets, detail family no. 2 (Fig. 18) were the source of numerous operational failures especially in the areas of hatch side girders and bulwark brackets. These girders, which carry high concentrated loads from containers stowed two to four high, must be provided with scantlings and tripping brackets to ensure proper support and load transfer during severe weather.

FIG. 28 Performance of Panel Stiffener Details (Family No. 12)
Standard Specification for Performance of Gasketed Mechanical Couplings for Use in Piping Applications

This standard is issued under the fixed designation F 1476; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This standard provides the performance characteristics and qualification tests required for gasketed mechanical couplings including grooved-type mechanical couplings for grooved end pipe, mechanical restraint couplings for plain end pipe and mechanical compression couplings for plain end pipe. These couplings are for use at temperatures within the recommended temperature range of their respective gaskets. Consult manufacturer for details.

1.2 The values stated in metric units (SI) are to be regarded as the standard. The values given in parentheses (inch/pound) are provided for information purposes.

1.3 Measuring and test equipment (M&TE) used in the performance of the tests described herein shall be calibrated using equipment which is traceable to the National Institute of Standards and Technology (NIST) or calibrated in accordance with the requirements detailed in BS5781 Part 1 against standards traceable to National Standards.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.5 As this is not a dimensional standard, nor does it contain component dimensions, the intermixing of sub-components such as gaskets and housings between manufacturers is not recommended and constitutes non-conformance with this standard.

2.1 ASTM Standards:
A 47 Specification for Ferritic Malleable Iron Castings
A 53 Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated Welded and Seamless
A 135 Specification for Electric-Resistance-Welded Steel Pipe
A 153 Specification for Zinc Coating (Hot-Dip) on Iron and Steel Hardware
A 183 Specification for Carbon Steel Track Bolts and Nuts
A 193 Specification for Alloy-Steel and Stainless Steel Bolting Materials for High-Temperature Service
A 194 Specification for Carbon and Alloy Steel Nuts for Bolts for High-Pressure and High-Temperature Service
A 325 Specification for Structural Bolts, Steel, Heat-Treated, 120/105 ksi Minimum Tensile Strength
A 395 Specification for Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures
A 536 Specification for Ductile Iron Castings
A 563 Specification for Carbon and Alloy Steel Nuts
A 574 Specification for Alloy Steel Socket-Hand Cup Screws
B 26/B26M Specification for Aluminum-Alloy Sand Castings
B 88 Specification for Seamless Copper Water Tube
B 580 Specification for Anodic Oxide Coatings on Aluminum
B 633 Specification for Electrodeposited Coatings of Zinc on Iron and Steel
D 2000 Classification System for Rubber Products in Automotive Applications
F 837 Specification for Stainless Steel Socket Head Cap Screws
2.2 ANSI, ANSI/ASQC, or ANSI/AWWA Standards:
B 36.10—Welded and Seamless Wrought Steel Pipe
B 36.19—Stainless Steel Pipe
C 151/A21.51—Ductile-Iron Pipe, Centrifugally Cast in Metal Molds or Sand-Lined Molds, for Water or Other Liquids

3. Terminology

3.1 Definitions:
3.1.1 class—differentiates joint characteristics such as rigid, flexible, restrained and unrestrained.
3.1.2 failure—any leakage or joint separation, unless otherwise determined to be due to a pipe or fitting defect.
3.1.3 fitting—a device used to change pipe direction, size or adapt to other joining methods. This device is used with pipe or other fittings to create a working system. Shapes such as elbows, tees, crosses, reducers and special shapes are used as needed to fulfill system design specifications.
3.1.4 flexible—characteristic of a joint wherein there is available limited angular and axial pipe movement.
3.1.5 gasketed mechanical coupling (GMC)—a device used to join pipe to pipe, pipe to fitting, or fitting to fitting wherein an elastomeric (gasket) is used to seal the joint. Coupling may or may not provide mechanical restraint of the pipe or fitting.
3.1.6 grade—the joint working pressure as established by tests using representative pipe or tube and the gasketed mechanical coupling (GMC). Test pipe or tube shall be:
NPS—Standard Weight Steel Pipe per ANSI B 36.10 and Specification A 53 Grade B, or Specification A 135 Grade B.
AWWA—Class 53 Ductile Iron Pipe per ANSI/AWWA C 151/A-21.51 for 3”–16”. For other sizes, consult manufacturer.
Tubing—Type K Copper Tube per Specification B 88.
Other—As agreed to by GMC manufacturer and purchaser.
3.1.7 grooved mechanical coupling (Type I)—a device which consists of two or more housings, closure members such as sets of bolts and nuts or pins, and a pressure-responsive gasket. It is used to mechanically join and seal grooved pipe or fitting, forming a joint. Grooves conform to ANSI/AWWA Standard C 606 as applicable. Groove dimensions for tubing and other sizes and types of pipes shall be as specified by the manufacturer. See Fig. 1.
3.1.8 plain end mechanical coupling:
3.1.8.1 (Type II—Classes 1 and 2)—Device consisting of gasket(s), housing(s), sleeve(s), end rings, threaded fasteners, pipe or fitting anchoring (gripping) features and seal retainers as applicable. These devices are used to create a seal and restrain plain end pipe or fittings. See Fig. 2 and Fig. 3.
3.1.8.2 (Type II—Class 3)—Device consisting of gasket(s), housing(s), sleeve, end rings and threaded fasteners as applicable. Tightening of the fasteners compresses the gasket(s), creating a seal on the outside of the plain end pipe. See Fig. 4.

FIG. 1 Type I Typical Construction

FIG. 2 Type II—Class 1 Typical Construction
3.1.9 joint—interface formed between pipe and pipe, pipe and fitting, or fitting and fitting where a GMC is used to seal within a specified working pressure this interface and where applicable, provide mechanical holding strength.

3.1.10 joint pressure rating—the working pressure for the joint on the pipe or fitting material and thickness to be used in the actual piping application.

3.1.11 leakage—the escape of fluid (gaseous or liquid) from any point of the specimen.

3.1.12 penalty run—a penalty run is performed with penalty run specimens when the original test specimen leaks or separates during testing as a result of any cause which is not related to the design of the GMC being qualified.

3.1.13 penalty run specimen(s)—additional specimen(s) which are tested in the place of the original specimen(s). These additional specimen(s) are assembled using the same methods along with additional GMC’s of the same type, grade, class, and configuration; and additional pipes or fittings with the same sizes, nominal wall thickness material and material condition as the original test specimen.

3.1.14 pipe—hollow tubular products conforming to ANSI B 36.10 and B 36.19, ANSI/AWWA C 151/A-21.51 Nominal Dimensions, or O.D. tube sizes.

3.1.15 pressure responsive gasket—gasket design such that application of a pressure load to the gasket enhances its sealing capabilities; that is, additional pressure results in additional force between the gasket and the surface to which it is sealing.

3.1.16 restrained—characteristic of the joint wherein thrust loads generated by internal pressure or external means are absorbed within the joint.

3.1.17 rigid—characteristic of a joint where there is essentially no available free angular or axial pipe movement.

3.1.18 specimen—a prepared assembly consisting of the test joint including GMC and pipes or fittings. The specimen is placed into a controlled environment and tested to determine if the joint performs to the standards established by the test.

3.1.19 type—differentiation of kind of pipe or fitting which gasketed mechanical couplings (GMC) are used to join (that is, grooved or plain end).

3.1.20 unrestrained—characteristic of a joint wherein thrust generated by internal pressure or external means is not absorbed by the joint but by other means such as pipe anchors or thrust blocks.

4. Classification

4.1 Gasketed mechanical couplings (GMC) are classified into the following design types:

4.1.1 Type I grooved mechanical couplings.

4.1.2 Type II plain end mechanical couplings.

4.2 The gasketed mechanical couplings (GMC) are classified into various grades based on successful completion of testing defined herein. Grades range from approximately 100 psi to 4000 psi and vary by GMC manufacturer. Consult GMC manufacturer for specific grades available.

4.3 The gasketed mechanical couplings (GMC) are classified by the following joint characteristics:

4.3.1 Class 1—rigid and restrained.

4.3.2 Class 2—flexible and restrained.

4.3.3 Class 3—flexible and unrestrained.

5. Ordering Information

5.1 Orders for GMC (Gasketed Mechanical Couplings) under this specification shall include the following:

5.1.1 ASTM designation, title, number and year of issue,

5.1.2 Quantity (number of gasketed mechanical couplings),

5.1.3 Size and appropriate suffix (examples: 8” NPS, 76.1 mm OD),

5.1.4 Type (I, II),

5.1.5 Grade (consult GMC manufacturer),

5.1.6 Class (joint characteristic),

5.1.7 Housing material and finish,

5.1.8 Gasket material,

5.1.9 Bolt (stud) and nut material and finish,

5.1.10 Supplementary requirements, if any,

5.1.11 Other requirements agreed to between purchaser and GMC manufacturer.

5.2 Optional Ordering Requirements:

5.2.1 Certification requirements,

5.2.2 Special marking requirements.

6. Materials and Manufacture

6.1 Type I—Grooved Mechanical Coupling:

6.1.1 Grooved Mechanical Coupling Housings:

6.1.1.1 Ferrous Materials—Housings shall be constructed of ductile iron in accordance with Specification A 395 Grade 60–40–18 or 65–45–15, Specification A 536, Grade 65-45-12 or malleable iron in accordance with Specification A 47, Grade 32510 or 35018.

6.1.1.2 Grooved mechanical coupling housings shall be coated with the manufacturer’s standard preparation and paint, or at the purchaser’s option, hot-dip galvanized in accordance with Specification A 153, or other finish as agreed upon between purchaser and manufacturer.

6.1.1.3 Aluminum Alloy Materials—Housings shall be constructed of aluminum alloy in accordance with Specification B 26, Grade 356-T6 or A 356-T6.
6.1.1.4 Finish for aluminum alloy housings shall be bare, anodized in accordance with Specification B 580 or as otherwise agreed between purchaser and manufacturer.

6.1.1.5 Iron-chromium-nickel, corrosion resistant material: Housings shall be constructed of iron-chromium-nickel alloy in accordance with Specification A 743/A 743M, Grade CF-8 or Grade CF-8M.

6.1.1.6 Finish for iron-chromium-nickel shall be bare or otherwise agreed between purchaser and manufacturer.

6.1.2 Grooved Mechanical Coupling — Gaskets shall be of materials suitable for the intended service. Elastomers shall comply with Classification System D 2000.

6.1.3 Grooved Mechanical Coupling — Bolting:

6.1.3.1 Carbon Steel Material — Bolts shall be in accordance with Specification A 183, Grade 2, Oval Neck. Nuts shall be in accordance with Specification A 194, Grade 2. Finish shall be black or at the purchaser’s option, zinc electroplated to Specification B 633.

6.1.3.2 Corrosion Resistant Material — Bolts shall be in accordance with Specification A 193, Grade B 8, Class 2 (AISI Type 304) or Specification A 193, Grade B 8M, Class 2 (AISI Type 316). Nuts shall be in accordance with Specification A 194 Grade 8.

6.2 Type II—Plain End Mechanical Coupling:

6.2.1 Plain End Mechanical Coupling Housings or Center Sleeves:

6.2.1.1 Cast Ferrous Materials — Cast housings or center sleeves shall be constructed of ductile iron in accordance with Specification A 395 Grade 60–40–18 or 65–45–15, Specification A 536, Grade 65-45-12 or malleable iron in accordance with Specification A 47, Grade 32510 or 35018.

6.2.1.2 Steel Materials — End rings and sleeves made from carbon or stainless steel shall be made from material with a minimum yield strength of 172 MPa (25,000 PSI).

6.2.1.3 Plain end mechanical couplings shall be coated with the manufacturer’s standard preparation and paint or other finish as agreed upon between the purchaser and manufacturer. Finish for iron chromium-nickel parts shall be bare or otherwise agreed upon between purchaser and manufacturer.

6.2.2 Plain End Mechanical Coupling — Gaskets shall be of materials suitable for the intended service (consult manufacturer for recommendation). Elastomer shall comply with Classification System D 2000 or BS 2494.

6.2.3 Plain End Mechanical Coupling — Bolting:

6.2.3.1 Carbon Steel Material — Bolts shall be in accordance with Specification A 183, Grade 2, Oval Neck or Specification A 325—Type 2 Heavy Hex; Cap screws shall be in accordance with Specification A 574 or BS 6104; Female threaded parts, other than nuts, shall be in accordance with Specification A 183, Grade 2; Nuts, if required, shall conform to Specification A 183, Grade 2 or Specification A 563—Grade C3 or DH3, or as otherwise agreed by purchaser and manufacturer. Finish shall be zinc electroplated to Specification B 633 or BS 1706.

6.2.3.2 Corrosion Resistant Material — Bolts or threaded female parts other than nuts shall be in accordance with Specification A 193, Grade B 8, Class 2 (AISI Type 304) or Grade B 8M, Class 2 (AISI Type 316); Cap screws shall be in accordance with F 837 or BS 6105; Nuts, if required, shall be in accordance with Specification A 194, Grade 8 or as agreed upon by purchaser and manufacturer.

6.3 Other Materials — Where other materials are required, the material and mechanical properties of the product shall be as agreed upon by the GMC manufacturer and the purchaser.

6.4 Material Quality:

6.4.1 The material shall be of such quality and purity that the finished product shall have the properties and characteristics to meet the performance requirements of this standard.
6.4.2 The manufacturer is encouraged to use materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. The term “recovered materials” means: “Materials which have been collected or recovered from solid waste and reprocessed to become a source of raw material, as opposed to virgin raw materials.” Used or rebuilt products shall not be used.

7. Other Requirements

7.1 Testing Requirements:

7.1.1 GMC shall be subjected to the tests described in the Annex for the purpose of qualifying the GMC design.

7.1.2 These tests shall be repeated when changes are made in the design, material, or manufacturing process that degrade the performance of the GMC. Degradation determination is to be made by the manufacturer or at agreement between the manufacturer and purchaser.

7.2 Qualification Requirements:

7.2.1 GMC shall be qualified using specimens of the same type, grade and class. Each type, grade, and class shall be tested in order to qualify the design. Qualification of the GMC requires successful completion of required testing. Each GMC design is only qualified for use on the pipe or fitting material and wall thickness on which it was tested.

7.2.2 All GMC’s tested shall be comprised of an equal number of specimens from the smallest, most intermediate size, and largest sizes within the size range of the GMC being qualified.

7.2.3 Through reasonable interpolations between the GMC sizes tested, other sizes of GMC’s within the same type, grade and class will be considered qualified if the specimens according to 7.2.2 pass the testing requirements. Extrapolation shall not be used for qualification purposes.

7.3 Qualification Test Report:

7.3.1 Upon completion of testing, a qualification test report shall be written and maintained on file during the life cycle of the design. A copy of this report shall be made available for inspection at the manufacturer’s facility.

7.3.2 Any failure during qualification testing shall be analyzed and the failure analysis and corrective action shall be included in the qualification test report.

7.3.3 A retest as specified in Section 11 (number of tests and retests) may be allowed when failure to the original joint occurs during qualification testing. When retesting is permitted, the failure analysis and corrective action shall be included in the qualification test report specified in 7.3.1.

7.4 Test Equipment and Inspection Facilities:

7.4.1 Test equipment and inspection facilities shall be of sufficient accuracy and quality to permit performance of required inspections and tests.

7.4.2 Calibration System Requirements—The testing and inspection facilities shall maintain a calibration system for Measuring and Test Equipment (M&TE) in accordance with ANSI Z 540.1 with traceability to the National Institute of Standards and Technology (NIST), or shall maintain a calibration system in accordance with the requirements detailed in BS 5781 Part 1 against standards traceable to National Standards.

7.5 Test Conditions:

7.5.1 Test pressures as specified within each test shall be used.

7.5.2 Fluid used in the testing of GMC shall be water or air, as specified.

7.5.3 Unless otherwise specified herein, GMC shall be tested within the temperature range stated by the type of test being performed.

Note 1—When no temperature is specified within a test, the test shall be conducted at ambient conditions.

7.6 Performance Requirements:

7.6.1 Pass criteria for each test shall require meeting or exceeding the performance requirements specified in each test.

8. Dimensions, Mass, and Permissible Variations

8.1 GMC Dimensions:

8.1.1 Type I GMC dimensions shall be as specified by the manufacturer and shall provide the degree of axial and angular deflection (as applicable) specified by the manufacturer when used on pipe grooved in accordance with ANSI/AWWA C-606, as applicable, or manufacturer’s recommendation(s).

8.1.2 Type II GMC dimensions shall be as specified by the manufacturer. Type II Class 2 shall provide angular deflection as specified by the manufacturer. Type II Class 3 GMC shall provide axial movement and angular deflection as specified by the manufacturer.

9. Workmanship, Finish, and Appearance

9.1 GMC Machined Surfaces:

9.1.1 Machined surfaces shall be free from burrs, cracks, laps, and seams which would affect the suitability for the intended service.

9.1.2 Machined surface finishes shall be as specified by the manufacturer.

9.2 Unmachined Surfaces:

9.2.1 Unmachined surfaces, such as forging or casting surfaces, shall be free from scale, blisters, fins, folds, seams, laps, segregations and cracks which would affect suitability for the intended service.

10. Sampling

10.1 In-process Inspection Sampling of GMC Products:

10.1.1 Inspection samples of GMC being manufactured or processed shall be selected in accordance with ANSI/ASQC Z 1.4. Level of inspection and acceptable quality level (AQL) shall be in accordance with the GMC manufacturer’s quality assurance procedures. Other inspection or sampling plans may be used upon mutual agreement between the manufacturer and the purchaser.

10.2 Lot Acceptance:

10.2.1 Lot acceptance shall be based upon meeting the sampling and pass/fail requirements of ANSI/ASQC Z 1.4. Other inspection or sampling plans may be used upon mutual agreement between the manufacturer and the purchaser.

11. Number of Tests and Retest, for Qualification Testing

11.1 Number of Test Specimens:

11.1.1 Each test shall be performed on specimens as denoted in Table A1.1.
11.2 Replacement of Test Specimens:
11.2.1 When untested specimens are rejected as a result of inferior workmanship or materials, or assembly, the specimens shall be dispositioned in accordance with the manufacturer’s quality assurance procedures.

11.2.1.1 New test specimens of the same type, grade, and class, and pipe or fittings of the same O.D. size and wall thickness shall be prepared in accordance with Section 12.

11.3 Penalty Runs:
11.3.1 In the event of not passing a test, the manufacturer shall proceed with one of the following options:
11.3.1.1 If the leak or separation is determined to be design related, the manufacturer shall redesign the GMC and start all tests from the beginning.
11.3.1.2 If the leak or separation is determined to be unrelated to the design, the test specimen shall be rerun. A replacement test specimen shall be prepared in accordance with the requirement specified in 11.2.
11.3.1.3 If the leak or separation cannot be shown to be either design related or non-design related, the manufacturer shall test three (3) additional penalty specimens. The requirements specified in 11.3.2 shall apply.
11.3.2 Penalty run specimens shall be prepared when GMC has failed any of the tests specified in the Annex.
11.3.2.1 The GMC’s used for penalty run(s) shall be of the same type, grade, and class as the failed GMC being replaced.
11.3.2.2 The pipe or fitting used in penalty runs shall be of the same material, O.D., and wall thicknesses as the pipe or fitting being replaced.
11.3.2.3 Preparation of the penalty run specimens shall be in accordance with Section 12.
11.3.2.4 Penalty run specimens shall be identified in accordance with 12.3 and 11.3.2.5.
11.3.2.5 In addition to the part number and test specimen number, a designator shall be placed after the test specimen number which allows the specimen to be identified as a penalty run specimen. The method used to identify penalty run specimens shall be at the manufacturer’s option.

12. Specimen Preparation
12.1 Specimen Preparation and Installation:
12.1.1 Specimen preparation and installation on appropriate testing apparatus shall be in accordance with the manufacturer’s recommended procedures.
12.2 Assembly of Specimens:
12.2.1 GMC qualified under the requirements of this specification shall be tested and qualified as a completed assembly; that is, joint.
12.2.2 The intermixing of sub-components of the same type, grade, and class, but of different brands or trade name, constitutes non-compliance with this standard.
12.2.3 Test specimens used in testing shall be assembled using a GMC of a single type, grade and class.
12.2.4 The wall thickness and O.D. size of the pipe or fitting shall be as specified for the GMC joint being qualified.
12.3 Identification of Test Specimens:
12.3.1 Each test specimen shall be identified with a unique number to provide traceability back to the test records.
12.3.2 Identification of test specimens shall be permanent. In those cases where size or design does not permit permanent markings, tagging or bagging may be used.
12.3.2.1 When, as a result of testing, a test specimen is sectioned into two (2) or more pieces, each piece shall be marked with the original unique identification number.
12.4 Test specimens may be disposed of following approval of the qualification test report by the GMC manufacturer.

13. Test Methods
13.1 Standard Qualification Tests for GMC shall be as specified in the Annex. The following tests described herein are required for GMC qualification as applicable to the type, grade and class.

13.2 Certification of Test Results:
13.2.1 When specified in the purchase order or the contract, the purchaser shall be furnished certification that samples representing the GMC have been tested as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the results shall be available for inspection at the manufacturer’s facility.

13.3 In-Process Material Tests—In-Process Material Tests shall be performed in accordance with manufacturer’s standard in-process test procedures.

14. Inspection
14.1 Terms of Inspection:
14.1.1 Inspection of GMC shall be in accordance with manufacturer’s standard inspection procedure or as agreed upon between the purchaser and the manufacturer or supplier as part of the purchase contract.
14.2 Raw Material Inspection:
14.2.1 Raw material shall be inspected for compliance with its material specification. A certificate of compliance or mill certificate shall be obtained from the material supplier, as applicable.
14.3 Quality Conformance Inspection:
14.3.1 GMC samples shall be visually and dimensionally examined to verify compliance with the manufacturer’s appropriate drawings.
14.4 Process Control Inspection:
14.4.1 GMC shall be inspected throughout the entire manufacturing and processing cycle. Methods of inspection shall be in compliance with manufacturer’s quality assurance procedures.
14.5 Inspection Records:
14.5.1 Inspection records shall be maintained by the manufacturer. The length of time on file shall be in accordance with the manufacturer’s quality assurance procedures.

15. Certification

15.1 Certification of Testing (see 13.2).

15.2 Certification of Material.

15.2.1 A certificate of compliance shall be obtained from the material supplier, when applicable. This certificate shall state that applicable requirements for the raw material have been met. As a minimum, the material specification shall specify the chemical and mechanical requirements of the material, as applicable.

16. Product Marking

16.1 Product Marking:

16.1.1 Each GMC shall be marked with the manufacturer’s name or trademark, size, and markings traceable to the type, grade and class. When shape or size does not permit inclusion of all required markings, the information may be omitted in the reverse order presented.

16.2 Additional Markings:

16.2.1 When specified in the contract or purchase order, additional markings other than those specified shall be applied, provided purchaser and supplier have agreed upon such prior to issuance of the contract or purchase order.

17. Packaging

17.1 The GMC shall be boxed, crated, wrapped and otherwise protected during shipment and storage in accordance with manufacturer’s standard practice. Care shall be taken to properly protect the GMC from distortion and other damage during shipment and storage. GMC’s may be shipped assembled; or bolts and gaskets may be packaged separately in suitable containers to withstand handling and storage.

18. Keywords

18.1 coupling; flexible; gasketed; grooved; plain end; rigid

ANNEXES

(Mandatory Information)

A1. PERFORMANCE TESTS FOR GMC

A1.1 Scope

A1.1.1 This section lists the tests to be used in the qualification of GMC. In addition, statements that apply to all tests are specified to minimize redundancy.

A1.1.2 The values stated in acceptable metric units are to be regarded as standard. The values given in parentheses (inch/pound) are provided for information purposes only.

A1.1.3 The tests required to qualify GMC may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulations/limitations prior to use.

A1.1.4 The test procedures appear in the following order:

<table>
<thead>
<tr>

A1.3.5 When pressure testing with water, test specimens shall be purged of air prior to pressurizing.

A1.3.6 End caps, adapters, and plugs used to block off a pipe or fitting end shall be of design(s) designated by the manufacturer. The end caps, adapters, and plugs shall be constructed to preclude their failure during testing.

A1.3.7 Failure of any test specimen which is related to separation or leakage at the end cap, adapter or pipe/fitting shall be recorded in the test report, but shall not be considered a failure of the GMC pipe or fitting combination being tested. Replacement test specimens shall be prepared in accordance with Section 12.

A1.3.8 Failure of any test specimen at the GMC pipe or fitting joint being proof tested constitutes failure of the GMC design.

A1.3.9 GMC shall be assembled in accordance with manufacturer’s recommended procedures.

A1.3.10 Qualification of GMC shall be based upon a successful passing of the tests described in Annex A2 through Annex A10. The flexibility test (see Annex A6) does not apply to Class 1 GMC’s, the rigidity test (see Annex A8) does not apply to Class 2 and 3 GMC’s and the bending moment proof test (see Annex A9) does not apply to Type II Class 2 or 3 GMC’s.

A1.4 Precision and Bias

A1.4.1 No statement is made about either the precision or bias of Section A1 “Performance Tests for GMC” since this section contains general information only.

A2. EXAMINATION OF SPECIMEN

A2.1 Scope

A2.1.1 This procedure covers the inspection and examination of test specimens prepared in accordance with the requirements specified in Section 12.

A2.2 Significance and Use

A2.2.1 GMC’s are comprised of couplings which are attached to or onto pipes or fittings using a variety of methods. In order to ascertain the integrity of each GMC type covered, it becomes important to subject all types of GMC to essentially the same tests. When the same tests are used, the assembly of some of the test specimens may become critical to the results of the test performed. The usefulness of this procedure lies in the examination of GMC test specimens to ensure that resulting assemblies duplicate appropriate stresses for all types of GMC qualified using the tests specified herein.

A2.3 Procedure

A2.3.1 GMC test specimens shall be assembled in accordance with the manufacturer’s assembly procedures.

A2.3.2 The materials used to assemble the test specimens shall be in accordance with Section 12. The pipe or fitting dimensions may vary (tolerances), as allowed by the manufacturer.

A2.4 Precision and Bias

A2.4.1 Precision is based upon the accuracy of the GMC dimensions in accordance with applicable drawings. The pipe or fitting used in conjunction with GMC shall be in accordance with specification(s) recommended by the manufacturer. There may be bias for the examination of specimen based upon the human elements involved in the visual inspection and measurement methods used.
A3. PNEUMATIC PROOF TESTING

A3.1 Scope
A3.1.1 This section covers pneumatic proof testing of GMC test specimens.

A3.2 Significance and Use
A3.2.1 This test is the initial test of all GMC specimens prepared for qualification. The test is performed by internally pressurizing the test specimen(s) using dry air or nitrogen (N\textsubscript{2}). A pressure of .55 MPa (80 psi) is applied. If the specimen shows no evidence of leakage, the specimen has successfully passed the test. This test is useful in determining if the GMC pipe or fitting connection has been assembled correctly, if the gasket is seated and installed correctly, and if the GMC design performs as proposed at this pressure.

A3.3 Procedure of Test
A3.3.1 The test specimen shall be placed in an appropriate chamber and secured in place in accordance with the manufacturer’s recommended procedures. Classes 1 and 2 shall not be longitudinally restrained. Class 3 shall be longitudinally restrained.

A3.3.2 The chamber shall be equipped with calibrated pressure gages (see A1.3.3) to permit visual readings of the actual internal pressure being applied.

A3.3.3 The pneumatic proof test shall be performed at ambient (see A1.3.2) temperature.

A3.3.4 Nitrogen (N\textsubscript{2}) or dry air shall be used to internally pressurize the test specimens to .55 MPa \textpm .03 MPa (80 psi \textpm 4.3 psi). A stabilization period shall be allowed to remove surface bubbles. The test period following stabilization shall be five minutes. There shall be no evidence of leakage during the test period. If leakage occurs during the test period, the test shall be discontinued and the affected specimens shall have failed the test. The test report shall be filled out noting the reason for discontinuing the test (see A1.3.7 and A1.3.8 for further information).

Method 1

The test joint shall be completely submerged in water (H\textsubscript{2}O) prior to beginning the test. Uppermost portion of GMC shall be no more than one foot below the surface of the water.

A3.3.6 If there is no evidence of leakage during the test period, the test specimens shall have passed the pneumatic proof test. If specimens do not pass this test, proceed per Section 11.

A3.4 Precision and Bias
A3.4.1 The precision of this test is the calibrated accuracy of the pressure gages. The gage(s) used to measure the internal pressure applied shall be calibrated to \textpm 1 \% throughout the range shown on the gage(s). There shall be no bias for Annex A3. Pneumatic Proof Testing, as the allowable test pressure tolerances of \textpm .03 MPa (4.3 psi) are well above the range of accuracy required to attain accurate readings.

A4. VACUUM PROOF TEST

A4.1 Scope
A4.1.1 This section covers Vacuum Proof Test of GMC test specimens.

A4.2 Significance and Use
A4.2.1 This test is performed by drawing an internal vacuum in the GMC test specimen, isolating the GMC by closing shut off valves and checking for loss of vacuum. The vacuum is internally applied to the assembled specimen to determine if it can maintain specified vacuum. If the specimen shows no loss of vacuum after 5 minutes, it shall pass the test.

A4.3 Procedure of Test
A4.3.1 The test specimen shall be placed in an appropriate test area and secured in place in accordance with the manufacturer’s recommended practice. Classes 1 and 2 shall not be longitudinally restrained. Class 3 shall be longitudinally restrained.

A4.3.2 The test set up shall be equipped with a calibrated vacuum gage(s) to permit visual readings of the actual vacuum being applied.

Method 2

Where submersion under water is impractical, leak detection using a soap type leak detecting fluid may be substituted.

A4.3.4 The pneumatic proof test shall be performed at ambient (see A1.3.2) temperature.

A4.3.5 Nitrogen (N\textsubscript{2}) or dry air shall be used to internally pressurize the test specimens to .55 MPa \textpm .03 MPa (80 psi \textpm 4.3 psi). A stabilization period shall be allowed to remove surface bubbles. The test period following stabilization shall be five minutes. There shall be no evidence of leakage during the test period. If leakage occurs during the test period, the test shall be discontinued and the affected specimens shall have failed the test. The test report shall be filled out noting the reason for discontinuing the test (see A1.3.7 and A1.3.8 for further information).

A4.3.6 If there is no evidence of leakage during the test period, the test specimens shall have passed the pneumatic proof test. If specimens do not pass this test, proceed per Section 11.
A4.4 Precision and Bias

A4.4.1 The precision of this test shall be the calibrated accuracy of the vacuum gages. The gage(s) used to measure the vacuum applied shall be calibrated to ±1 % or better throughout the range shown on the gage(s). There shall be no bias for A4 Vacuum Test, as the allowable vacuum tolerances of ±5 % are well above the range of accuracy required to attain accurate readings.

A5. HYDROSTATIC PROOF TESTING

A5.1 Scope

A5.1.1 This section covers hydrostatic proof testing of GMC test specimens.

A5.2 Significance and Use

A5.2.1 This test is performed by internally pressurizing the test specimens using water. The initial pressure applied, .690 MPa (100 psi), tests the assembled specimen to determine if it can retain fluid without wetting of the external surface or leakage at the GMC joint. If there is no leakage, the pressure is gradually increased to 150 % of the proposed rated pressure of the pipe or fitting GMC joint. This elevated pressure level tests the ability of the specimens to hold fluid without wetting of the surface, and not to leak or fail structurally. Holding time for this pressure test shall be 10 min.

A5.2.2 If the specimen still shows no evidence of leakage after this test, the specimens shall pass the test. This test is useful in determining the integrity of the fitting joint to hold fluid at an elevated pressure without any wetting of the surface or leakage. After successful completion of this test, the test specimens are ready for additional testing (see Table Test Sequence).

A5.3 Procedure of Test

A5.3.1 Test specimens shall be installed onto an appropriate testing apparatus, filled with water and purged of all air.

A5.3.2 The test specimens shall be placed in a burst chamber and secured into place in accordance with the manufacturer’s recommended procedures. Class 1 and 2 GMC shall be tested with no longitudinal restraint provided by the test operator. Class 3 GMC shall be longitudinally restrained.

A5.3.3 The chamber shall be equipped with calibrated pressure gages (see A1.3.3) to permit visual readings of actual internal pressure being applied.

A5.3.4 The hydrostatic proof test shall be performed at ambient temperature (see A1.3.2).

A5.3.5 The test specimens shall be initially pressurized to .690 MPa (100 psi) ± .03 MPa (4.3 psi) for a total period of 5 min. There shall be no evidence of wetting of the surface or leakage during this 5-min period. If wetting of the surface or leakage occurs, the test shall be discontinued and the affected specimens shall fail the test. Proceed per Section 11.

A5.3.6 If there is no evidence of leakage after the initial 5 min period, the internal pressure shall be gradually increased at a rate not to exceed 138 MPa/min (20 000 psi/min) to 150 % ± 5 % of the proposed rated pressure of the pipe or fitting GMC joint. This pressure shall be maintained for an additional period of 10 min. There shall be no evidence of wetting of the external surface or leakage during this 10-min period. If wetting of the surface or leakage occurs, the test shall be discontinued and the affected specimens shall fail the test. Proceed per Section 11.

A5.3.7 If there is no evidence of wetting of the external surface or leakage within the fitting area or joint during both pressurized periods, the test specimens shall pass the hydrostatic proof test.

A5.4 Precision and Bias

A5.4.1 The precision of this test shall be the calibrated accuracy of the pressure gages. The gages used to measure the pressures applied shall be calibrated to ±1 % or better throughout the range shown on the gages. There shall be no bias for A5 hydrostatic proof test, as the allowable tolerances (±5 %) are well above the range of accuracy required to attain accurate readings during both pressurized periods.

A6. FLEXIBILITY PROOF TEST

A6.1 Scope

A6.1.1 This section covers flexibility proof testing of Types I & II Class 2 and Type II Class 3 GMC.

A6.2 Significance and Use

A6.2.1 The significance of this test is to verify the axial pipe and angular pipe movement available with Types I & II Class 2 and Type II Class 3 couplings.

A6.2.1.1 Type I Class 2—The test for axial movement is performed by assembling the GMC with the pipe or fitting ends fully inboard and then pressurized to extend the joint to its furthest extended position. The test for angular movement is performed by applying bending moment from Table A6.1 (see Note 2) to the joint and measuring the resultant angular deflection.

A6.2.1.2 Type II Class 2—The test for angular movement is performed by filling and pressurizing the GMC with water to the proposed working pressure, then deflecting the joint to the test angle. The test angle shall be the maximum deflection angle specified by the manufacturer. No leakage shall be allowed during or after this deflection. No permanent damage shall occur to the GMC.

A6.2.1.3 Type II Class 3—The test for axial movement shall be performed by assembling the GMC in accordance with the manufacturer’s instructions. The joint shall then be pressurized...
to its proposed working pressure, while allowing the pipe to move longitudinally to the maximum allowable movement specified by the manufacturer. No leakage shall be allowed during or after this movement. The test for angular movement shall be performed by assembling the GMC with the pipe in the deflected position, and filling and pressurizing with water to the working pressure. The deflection angles shall be as recommended by the manufacturer.

A6.3 Procedure of Test

A6.3.1 Type I Class 2—Pipe shall be grooved (roll or cut as applicable) in accordance with ANSI C 606 as applicable or manufacturer’s recommendation(s) and a line scribed 1 in. from each groove away from pipe end. The GMC shall be assembled with the pipe ends touching or as fully inboard as the GMC permits. The distance between the two scribe lines shall be measured and recorded. The specimen shall not be longitudinally restrained. The specimen shall be filled with water and pressurized to .69 MPa (100 psi) or 25 % of GMC proposed rating, whichever is larger. The new distance between the scribe lines shall be measured and recorded. The difference between the two scribe line measurements is the measured axial movement. The test for angular movement consists of applying a small bending moment per Table A6.1 (see Note 2) to the same assembled specimen from above with no internal pressure and measure the total deflected angle achieved. The angle shall be measured using an inclinometer or by measuring the deflection and distance between the support points and calculating the angle.

A6.3.2 Type II Class 2—Prepare the pipe in accordance with the coupling manufacturer’s recommendations. The test shall be performed by assembling the GMC onto the pipe, filling and pressurizing with water to the proposed working pressure, and deflecting the joint to the test angle. The test angle shall be the maximum deflection angle specified by the manufacturer. No damage to the GMC or leakage shall be allowed during the test. Holding time for this test shall be no less than 10 min. The deflection angle shall be measured using an inclinometer or by measuring the deflection and distance between the support points and calculating the angle.

A6.3.3 Type II Class 3—The pipe shall be prepared in accordance with the coupling manufacturer’s recommendations. The GMC shall be assembled with pipes at their most in-board position. A line shall be scribed 1 in. from the outside of the coupling on each pipe. The distance between the two scribed lines shall be measured and recorded. The specimen shall be pressurized and filled with water to its working pressure. The restraint on the pipe shall be adjusted to provide 10 mm (3⁄8 in.) of total longitudinal movement for 254 mm (10 in.) and larger pipe. Smaller size shall be tested in accordance with manufacturer’s published limits. No leakages shall be allowed during this test. Movement shall be determined by measuring between the two scribed lines and subtracting the original line spacing. The test for angular movement shall be performed by assembling the GMC with the pipe in the deflected position, and filling and pressurizing with water to the working pressure. The deflection angles shall be the maximum deflection angle specified by the manufacturer. No leakage shall be allowed when the GMC is pressurized. The data for this test shall be recorded and used for future reference. The test shall be repeated for each possible combination of pipe and coupling to ensure consistency and accuracy.

### Notes

1. For sizes and wall thicknesses not listed.
2. Use 10 % of Moments listed for flexibility tests.
3. Use 25 % of Moments listed for rigidity tests.
4. Values in table are for NFPA 13 Hanger Spacing.

### Table A6.1 Bending Moments for Flexibility (Note 2) Rigidity (Note 3) and Proof Test Pipe Schedule

**METHOD FOR CALCULATING TEST MOMENT**

\[ M = F (L) \]

- **F** = Weight of Pipe + Weight of Water
- **L** = \( \frac{1}{2} \) (Hanger Spacing)

EX: For 2\(^{nd}\) Schedule 40 steel pipe with NFPA Hanger Spacing where \( L = 7\frac{1}{2} \) ft

\[ F = 3.653 (15) + 40.27 (15) (0.36) \]

Where 3.653 is the pounds per foot of 2\(^{nd}\) Schedule 40 pipe, 40.27 is the cubic inches of water per foot of 2\(^{nd}\) Schedule 40 pipe, .036 is the pounds per cubic inch of water, 15 is total length of pipe in feet.

\[ F = 54.796 + 21.746 = 76.542 \text{ pounds} \]

**NOTE 2**—For sizes and wall thicknesses not listed.
A6.3.4 The flexibility proof test shall be performed at ambient temperature (see A1.3.2).

A6.4 Precision and Bias

A6.4.1 The precision of this test shall be the calibration accuracy of the measuring equipment. The calipers used to measure the movement shall be calibrated to .03 mm (.001 in.) throughout its range. The inclinometer shall be zeroed prior to each reading. The accuracy of the readings is dependent solely on the ability to read the scales typically ±1°. There may be bias for the examination of the movement based upon the human elements involved in the visual inspection used.

A7. HYDROSTATIC BURST TEST

A7.1 Scope

A7.1.1 This section covers the test requirements for burst testing.

A7.2 Significance and Use

A7.2.1 This test verifies the mechanical integrity of the pipe or fitting and GMC to withstand, without leakage or burst, a minimum pressure equal to three times the proposed rated pressure of the pipe or fitting and GMC, which form a joint. To successfully pass this test, the pipe or fitting and GMC shall not leak or burst.

A7.3 Procedure of Test

A7.3.1 Test specimens shall be filled with water prior to installation onto the appropriate testing apparatus and purged of entrapped air.

A7.3.2 The test specimens shall be placed in a burst chamber. Class 1 and 2 GMC shall not be longitudinally restrained.

A7.3.3 The chamber shall be equipped with calibrated pressure gages (see A1.3.3) to permit visual readings of actual pressure being applied.

A7.3.4 The hydrostatic burst test shall be performed at ambient temperature (see A1.3.2).

A7.3.5 Class 1 test specimens shall be subjected to a gradual increase of pressure at a rate not to exceed 138 MPa/min to three times the proposed rated pressure of the specimen assembly. If leakage or burst occurs below three times the proposed rated pressure of the specimen assembly, the test shall be discontinued and the affected test specimens shall fail the test for the proposed rating. The test report shall be filled out noting the reason for discontinuing the test. See A1.3.4 or A1.3.5 for further information. If there is no evidence of leakage or burst when three times the proposed rated pressure of the specimen assembly is attained, the pressure shall be gradually increased until burst occurs. The test specimens have passed the hydrostatic burst test when three times the proposed rated pressure of the specimen assembly has been attained. Pressure attained at the time of burst shall be recorded in the Qualification Test Results.

A7.3.6 For Class 2 and Class 3 GMC’s, the specimen shall be mounted in a test fixture such that the joint is held fixed at its maximum angular deflected position (determined from the test in Annex A6). This test specimen shall then be subjected to a gradual increase of pressure at a rate not to exceed 138 MPa/min (20 000 psi/min) to three times the proposed rated pressure of the specimen assembly. If leakage or burst occurs before three times the proposed rated pressure of the specimen assembly, the test shall be discontinued and the affected test specimens shall fail the test for the proposed rating. If there is no evidence of leakage or burst when three times the proposed rated pressure of the specimen assembly is attained, the pressure shall be gradually increased until burst occurs. The test specimens have passed the hydrostatic burst test when three times the proposed rated pressure of the specimen assembly has been attained. Pressure attained at the time of burst shall be recorded in the Qualification Test results.

A7.4 Precision and Bias

A7.4.1 The precision of this test shall be the calibrated accuracy of the pressure gages. The gages used to measure the pressures applied shall be calibrated to ±1 % or better throughout the range shown on the gages. There may be bias in this test if the pipe or fitting selected bursts below three times its proposed rated pressure. If this occurs, the test specimens may be replaced in accordance with A1.3.7. There also may be bias based upon the human elements involved in the visual inspection used.
A8. RIGIDITY PROOF TEST

A8.1 Scope

A8.1.1 This section covers rigidity proof testing of Class 1 GMC specimens.

A8.2 Significance and Use

A8.2.1 The significance of this test is to demonstrate the suitability of the GMC for use when the piping system is supported as a rigid system. The test is performed by applying a moment to the specimen equal to the maximum moment generated by the pipe when filled with water and supported at the maximum allowable hanger spacing (see Table A6.1, Note 3). The GMC is to be pressurized with water to its rated pressure during application of the bending moments. The GMC shall pass this test if the included angle of the pipe sections adjacent to the GMC does not change by more than angle $\Theta$ with the test moment applied at the GMC, and there is no evidence of leakage.

$$\Theta = 60' \text{ (minutes)} - [2' \text{ (minutes)} \times (\text{nominal pipe size in inches})].$$

A8.3 Procedure of Test

A8.3.1 The test shall be conducted with a specimen using test pipe not less than .38 m (15 in.) in length. The support points for the pipe shall be not less than .305 m (12 in.) from the GMC. The test load may be applied directly to the GMC or to the pipe adjacent to the GMC with appropriate load adjustment. The joint shall be internally pressurized to the proposed rated pressure ($\pm$ 5 %) of the GMC pipe or fitting (specimen), whichever is lower. The initial included angle shall be measured and recorded. Do not apply any bending moment while measuring the initial angle. The bending moment listed in Table A6.1 shall be applied (see Note 3) to the joint. The final included angle shall then be measured and recorded. The deflection angle shall be determined either by measuring the movement of the GMC and calculating the angle or by direct measurement. The test shall be conducted at ambient temperature (see A1.3.2). If there is no evidence of leakage and the included angle has not changed more than angle $\Theta$, the GMC shall pass the test. $\Theta$ shall be calculated as follows: $\Theta = 60' \text{ (minutes)} - [2' \text{ (minutes)} \times (\text{nominal pipe size in inches})].$

A8.4 Precision and Bias

A8.4.1 The precision of this test shall be the calibrated accuracy of the pressure gages and the accuracy of the reading of the inclinometer or dial gage. The gages used to measure the pressure applied shall be calibrated to $\pm 1 \%$ or better throughout the range used for the test. The inclinometer shall be zeroed prior to each reading. Therefore, the accuracy of the readings is dependent solely on the ability to read the scales, typically $\pm 1 \%$. There may be bias for the visual reading of the inclinometer or dial gage based upon the human elements involved in the visual reading of the meter(s).

A9. BENDING MOMENT PROOF TEST

A9.1 Scope

A9.1.1 This section covers the bending moment proof test for Type I Class 1 and 2 and Type II Class 1 GMC specimens.

A9.2 Significance and Use

A9.2.1 This test verifies the ability of the GMC to resist a bending moment equal to the bending moment generated by the pipe when filled with water, supported at one side of the GMC by a hanger and with the next hanger broken on the maximum allowable hanger spacing. The GMC is to be pressurized to its proposed rated pressure $\pm 5 \%$ during the test. The GMC shall have passed this test if it withstands this moment without failing and no evidence of leakage is observed.

A9.3 Procedure for Test

A9.3.1 The test shall be conducted with a specimen using test pipe at least .38 meters (15 inches) in length. The support points for the pipe shall be a minimum of .305 meters (12 inches) from the GMC. The test load may be applied directly to the GMC or on the pipe adjacent to the GMC. In either case, the applied load shall be such that the test moment acts at the GMC. The joint shall be pressurized to the proposed rated pressure ($\pm 5 \%$) of the specimen. The moment (see Table A6.1) shall be applied to the joint and held for not less than one minute. The test shall be conducted at ambient temperature (see A1.3.2). If the GMC withstands this moment and shows no evidence of leakage, it shall pass this test.

A9.4 Precision and Bias

A9.4.1 The precision of this test shall be the calibrated accuracy of the pressure gages and the accuracy of the reading of the inclinometer or dial gage. The gages used to measure the pressure applied shall be calibrated to $\pm 1 \%$ or better throughout the range used for the test. There is no bias for this test because the allowable tolerance of $\pm 5 \%$ is well above the range of accuracy required to attain accurate readings.
A10.1 Scope
A10.1.1 This section covers the bending moment ultimate test for Type I Class 1 and 2 and Type II Class I GMC specimens.

A10.2 Significance and Use
A10.2.1 This test verifies the safety factors available in the GMC when tested with the bending moment from Annex A8 and Annex A9. This test is performed by pressurizing the specimen to its proposed rated pressure and then applying a bending moment to cause failure. The pressure is maintained at the proposed rated pressure throughout the test. The test is conducted at ambient temperature (see A1.3.2). A specimen that withstands two times the bending moment for Annex A9 without failure has passed this test.

A10.3 Procedure for Test
A10.3.1 The test shall be conducted with a specimen using test pipe not less than .38 meters (15 inches) in length. The support points for the pipe shall be not less than .305 meters (12 inches) from the GMC. The test load may be applied directly to the GMC or on the pipe adjacent to the GMC. In either case, the applied load shall be such that the described test moment acts at the GMC. This test shall be conducted at ambient temperature (see A1.3.2). The joint shall be internally pressurized to the proposed rated pressure (±5 %) of the specimen. Increasing moments shall be applied to the GMC while maintaining the internal pressure at the proposed rated pressure until failure occurs. This bending moment shall be applied at a rate not to exceed 27,116 Newton meters (20,000 Ft-Lbs) per minute. GMCs that withstand two times the test moment from Annex A9 without evidence of leakage shall pass the test. The moment at failure shall be recorded.

A10.4 Precision and Bias
A10.4.1 The precision of this test shall be the calibrated accuracy of the pressure gages. The gages used to measure the pressure applied to the specimen and to the bending apparatus, as applicable, shall be calibrated to ±1 % or better throughout the range used for the test. There is no bias for this test because the allowable tolerance of ±5 % is well above the range of accuracy required to attain accurate readings.

Standard Specification for
Surge Suppressors for Shipboard Use

This standard is issued under the fixed designation F 1507; the number immediately following the designation indicates the year of
original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A
superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This standard establishes performance requirements of
surge suppressors for use on shipboard ac power circuits.

1.2 Surge suppressor shall be a protective device for limit-
ing voltage transients on equipment by discharging, dissipating
internally, bypassing surge current, or a combination thereof
and which prevents continued flow of follow current to ground
and is capable of repeating these functions.

1.3 Surge suppressors covered by this specification may
consist of a single circuit element or may be a hybrid device
using several suppression devices.

2. Referenced Documents

2.1 The following documents of the issue in effect on the
date of material purchase form a part of this specification to the
extent referenced herein:

2.2 American National Standards:²
ANSI/IEEE Std 4 IEE Standard Techniques for High
Voltage Testing
ANSI/IEEE C62.41 Recommended Practice on Surge Volt-
age in Low-Voltage AC Power Circuits
Connected to Low-Voltage AC Power Circuits
ANSI/IEEE C84.1 Electrical Power Systems and
Equipment—Voltage Ratings

2.3 Military Standard:³
MIL-STD-1399 Section 300; Military Standard Interface
Standard for Shipboard Systems, Section 300, Electric
Power, Alternating Current

2.4 Underwriters Laboratories Standard:⁴
UL 1449 Transient Voltage Surge Suppressors, 2nd Edition

3. Terminology

3.1 Definitions:

NOTE 1—These definitions other than specific to the standard are taken
from UL 1449, ANSI/IEEE C62.41, and MIL-STD 1399 to provide for
harmonization of terms.

3.2 power interface—The electrical points where the surge
suppression device is electrically connected to the ac power
system.

3.3 combination wave—A surge delivered by an instrument
that has the inherent capability of applying a 1.2/50-µs voltage
wave across an open circuit and delivering an 8/20-µs current
wave into a short circuit. The exact wave that is delivered is
determined by the instantaneous impedance to which the
combination wave is applied. (Also called combination
voltage/current surge or combination V/I surge.)

3.4 crest (peak) value (of a wave, surge or impulse)—The
maximum value that a wave, surge, or impulse attains.

3.5 electric power source—The electric power that is sup-
plied for testing.

3.6 electric power system ground—Ground is a plane or
surface used by the electric power system as a common
reference to establish zero potential. Usually, this surface is the
metallic hull of the ship. On a nonmetallic hull ship, a special
ground system is installed for this purpose.

3.7 follow (power) current—The current from the connected
power source that flows through a surge protective device
following the passage of discharge current.

3.8 frequency tolerance—Frequency tolerance is the max-
imum permitted departure from nominal frequency during
normal operation, excluding transient and cyclic frequency
variations. This includes variations such as those caused by
load changes, switchboard frequency meter error, and drift.
Unless specified otherwise, frequency tolerance shall be con-
sidered to be ±10 % of nominal frequency.

3.9 inrush current—The inrush current is a sudden change
in line current that occurs during startup or as a result of a change
to the operating mode. Inrush current is dependent on
the type of load connected to the surge suppressor, and
typically will rise to a maximum value in a few milliseconds
and decay to rated value in several milliseconds to several
seconds.
3.10 leakage current—Line current drawn, either line-to-line or line-to-ground, by the suppressor when operated at the maximum continuous operating voltage.

3.11 maximum continuous operating voltage—Maximum sinusoidal rms voltage which may be continuously applied without degradation or deleterious effects.

3.12 measured limiting voltage—The crest (peak) value of the voltage measured at the leads, terminals, receptacle contacts and the like, intended for connection to the load(s) to be protected, and resulting from application of a specified surge.

3.13 nominal frequency—the nominal frequency is the designated frequency in Hz.

3.14 nominal system voltage—A nominal value assigned to designate a system of a given voltage class in accordance with ANSI/IEEE C84.1. For the purpose of this standard, nominal system voltages are 120, 208, 240, and 480 vac. All voltages in this standard are root-mean-square (rms) unless stated otherwise. All tolerances are expressed in percent of the nominal system voltage.

3.15 one-port transient voltage surge suppressor—A TVSS having one set of electrical connections (terminals, leads and the like) intended only for shunt-connection to the ac power circuit, such that load current in the ac power circuit bypasses the TVSS.

3.16 peak overshoot voltage—Maximum voltage above the voltage protection level (peak voltage minus suppression voltage rating) across the suppressor output terminals during initial response to a voltage spike.

3.17 rated rms voltage (varistor)—Maximum continuous sinusoidal rms voltage which may be applied to a varistor.

3.18 response time (varistor)—The time between the point at which the wave exceeds the voltage protection level (suppression voltage rating) and the peak of the voltage overshoot. For the purpose of this definition, voltage protection level is defined with an 8/20-µs current waveform of the peak current amplitude as the waveform used for this response time.

3.19 secondary surge arrester—A surge protector device acceptable ahead of the service entrance equipment on circuits not exceeding 1000-V rms (location category C as described in ANSI/IEEE C62.41).

3.20 surge—A transient overvoltage superimposed on the ac power circuit. A voltage surge is generally one in which the superposition of the surge and normal power frequency voltage involves peak voltage levels of twice or more the normal voltage of the ac power system and generally lasting not more than one-half period of the nominal system voltage waveform.

3.21 surge protective device (SPD)—A protective device composed of any combination of linear or non-linear circuit elements and intended for limiting surge voltages on equipment by diverting or limiting surge current; it prevents continued flow of follow (power) current and is capable of repeating these functions as specified.

3.22 temporary overvoltage (TOV)—A voltage swell from a sudden change in voltage which goes outside the voltage tolerance limits but does not exceed 120 % of nominal system voltage and returns to and remains within these limits within 2 s after the initiation of the disturbance.

3.23 transient voltage surge suppressor (TVSS)—A surge protective device intended for connection electrically on the load side of the main overcurrent protection in circuits not exceeding 600 V. (Location Categories A and B as described in ANSI/IEEE C62.41.)

3.24 two-port transient voltage surge suppressor—A TVSS having one set of electrical connections (terminals, leads and the like) intended for connection to the ac power circuit and one or more separate sets of electrical connections (terminals, leads, outlet receptacles, and so forth) intended for connecting the load(s) to be protected. This device is series-connected such that load current will flow through the transient voltage surge suppressor.

3.25 voltage drop—Voltage differential measured from input terminals to output terminals under conditions of rated load current for two-port surge suppressors.

3.26 voltage protection level—A suppression rating (or ratings) in volts or kilovolts, selected by the manufacturer that is based on the measured limiting voltage determined during surge testing. Also referred to as the suppression voltage rating.

3.27 voltage spike—A voltage spike is a voltage change of very short duration (100 µs to ½ cycle). The standard 1.2/50-µs lightning impulse, as defined by ANSI/IEEE Std 4, is the characteristic voltage spike used for test purposes.

3.28 voltage tolerance—Voltage tolerance is the maximum permitted departure from nominal system voltage during normal operation, excluding transient voltage variations. Voltage tolerance includes variations such as those caused by load changes, switchboard meter error, and drift. Unless otherwise specified, voltage tolerance shall be considered to be ± 10 % of nominal system voltage.

4. Classification

4.1 Surge suppressors covered in this specification shall be classified by class and type.

4.2 The two classes of surge suppressors covered in this specification are based on and reflect ANSI/IEEE C62.41 locations.

4.2.1 Class A—Surge suppressor associated with long circuit branch that being greater than 30-ft cable distance from the distribution panel and usually installed as a series-connected TVSS at the distribution system receptacle (wall outlet).

4.2.2 Class B—Surge suppressor for short branch circuit, either installed at loads within 30-ft cable distance from the circuit breaker distribution panel or within the distribution panel.

4.3 Type designations for surge suppressors covered in this specification are as follows:

4.3.1 Type I; Permanent Connected Type—A suppressor designed for hard-wired or panel-mounted applications. This type surge suppressor is the only one-port-type TVSS.

4.3.2 Type II; Plug-In Type—A suppressor provided with blades for direct connection at a receptacle and with integral output receptacle(s). By nature of its design, a plug-in suppressor is inserted into the circuit as a series connection.

4.3.3 Type III; Cord-Connected Type—A suppressor that is connected to a receptacle through a flexible cord that is permanently attached to the suppressor device. The cord shall
be in accordance with requirements of UL 1449. Cord-connected devices shall not have means for permanent mounting.

4.3.4 **Type IV: Power Director (Power Center) Type**—A suppressor unit with two-pole main circuit breaker, a master switch for controlling all receptacle outlets, and individual switches for controlling all outlets.

5. **Ordering Information**

5.1 Orders for suppressors under this specification shall include the following:

5.1.1 This specification number;
5.1.2 Nominal system voltage—120, 208, 240, and 480 V;
5.1.3 Frequency—50, 60, and 400 Hz;
5.1.4 Service—single-phase, three-phase delta, three-phase wye;
5.1.5 Load current;
5.1.6 Surge suppressor—class and type;
5.1.7 Protection modes;
5.1.8 Voltage protection level (suppression rating), if known;
5.1.9 Quantity;
5.1.10 Testing requirements—include only if tests other than the production tests required by this specification are to be performed;
5.1.11 Certification requirements; and
5.1.12 Packaging and shipping requirements.

6. **Materials and Manufacture**

6.1 **Materials**—All materials used in the construction of these surge suppressors shall be of a quality suitable for the purpose intended and shall conform to the requirements of this specification.

6.1.1 All metallic enclosures shall be either painted or coated with corrosion resistant material.

6.2 **Manufacture**—Plastic, when used, shall be a suitable thermoplastic or thermoetting material so molded as to produce a dense solid structure, uniform in texture, finish, and mechanical properties.

7. **Requirements**

8. **Performance Requirements**:

8.1 Surge protective devices that are series-connected (Types II, III, and IV) shall have supplementary overcurrent protection and overtemperature protection.

8.4 Supplementary overcurrent protection using fuses shall be readily replaceable while circuit breaker protected devices shall be replaceable.

8.4.1 Surge protective devices that are series-connected (Types II, III, and IV) shall have supplementary overcurrent protection and overtemperature protection.

8.4.2 Supplementary overcurrent protection using fuses shall be readily replaceable while circuit breaker protected devices shall be replaceable.

8.4.3 Supplementary overcurrent protection shall interrupt all phases of the source circuit plus the circuit neutral where applicable to assure suppressor isolation of the load.

8.4.4 Overtemperature protection shall sense suppressor enclosure or suppression device overtemperature condition and initiate opening of the voltage supply.

8.4.5 Suppressor supplementary protection shall provide a visual or audible indication or both of the opening of the protective device.
8. Enclosures

8.1 Unless specified differently by the purchaser, the suppressor shall be packaged in a safety grounded enclosure with foundation attachments that meets the requirements of UL 1449.

8.1.1 The enclosure shall be capable of confining any material that may be expelled during a catastrophic failure of any suppression device.

9. Receptacles

9.1 Receptacles provided as part of a suppressor shall have a current rating not more that the current rating of the suppressor and a voltage rating consistent with rating of the suppressor.

9.2 All receptacles shall be of the grounding type.

10. Design Tests

10.1 Insulation Withstand Test—The assembled insulating members of the surge suppressor shall withstand impulse and power-frequency voltages applied between each pair of line terminals and between each line terminal and the grounded case. Internal parts designed to conduct to discharge impulses shall be removed or rendered inoperative to permit these tests.

10.1.1 Impulse Insulation Withstand—A 1.2/50-µs impulse voltage wave, as defined by ANSI/IEEE Std 4, shall be applied between each set of line terminals and between each line terminal and ground. The magnitude of the impulse voltage shall be at least 1.2 times the sum of the voltage protection level (suppression rating) and the maximum peak overshoot voltage, but need not exceed 6 kV.

10.1.2 Power Frequency Insulation Withstand—An ac potential of the nominal system frequency shall be applied for a period of 1 min between each set of line terminals and between each line terminal and ground. The magnitude of the test voltage shall be 1000 V plus twice nominal system voltage. The same test voltage magnitude shall be applied for line-to-line and line-to-ground tests.

10.2 Power Frequency Withstand Test—Power frequency withstand tests shall be performed to demonstrate the ability of the surge suppressor to withstand sustained periods of operation at the maximum continuous operating voltage and periods of transient power frequency overvoltage without degradation. The power supply voltage, measured at the input terminals of the suppressor, shall be maintained as close as practicable to, but not less than, the specified test voltage. Three suppressors shall be connected across a power supply within the tolerances of the nominal frequency. The power supply shall have a short circuit capacity, measured at the suppressor input terminals, of at least 500 amps. For multi-phase suppressors, tests shall be performed for the assembled suppressor and power frequency voltage shall be applied to all phases.

10.2.1 Maximum Continuous Operating Voltage—The three test samples shall be placed in a controlled-temperature chamber with an ambient temperature of 85°C ± 5°C and the rated maximum continuous operating voltage shall be applied for a period of 1000 h. The suppressor leakage currents shall be measured at the beginning of the test (after the suppressor temperature has stabilized), and again after 1000 h. The leakage currents at the conclusion of the test shall be less than 30 mA and shall be less than 110 % of the initial leakage current for each sample.

10.2.2 Maximum Line-to-Ground Voltage—Rated maximum continuous operating voltage shall be applied to the three test suppressors between each line terminal and ground for a period of 1 h. A single-phase voltage source may be applied between all line terminals (in parallel) and ground for this test. Leakage current to ground shall not increase by more than 10 % at the conclusion of this test.

10.2.3 Temporary Overvoltage—The three test samples shall be exposed to ten cycles of temporary overvoltage. Each overvoltage cycle shall consist of 120 % of rated nominal voltage for a period of 2 s followed by the maximum continuous operating voltage for a period of 1 min. The leakage currents shall not exceed 30 Ma and the leakage current immediately following the 1-min period of the last cycle shall not exceed 110 % of the value obtained at the conclusion of the maximum continuous operating voltage test.

10.3 Impulse Voltage-Time Tests—The impulse voltaged-time tests demonstrate the suppressor’s ability to limit over-voltage in response to varying voltage spike rates of rise. Voltage impulses with fast (5 kV/µs) and slow (150 V/µs) rates of rise and of both polarities shall be applied between each set of input line terminals and between each line terminal and ground. Normal operating voltage need not be applied for these tests. The tests shall be performed on three samples, and the highest crest voltage recorded at the output terminals shall be less than the maximum peak voltage (voltage protection level plus peak overshoot). The response time shall also be less than 50 ns. For one-port type suppressors, input and output terminals are the same terminals. Where three-phase suppressors consist of three identical circuits, these tests need only be performed on one of the three circuits in each sample. If the suppressor discharge current exceeds 3000 amps, a resistance of up to 2 Ω may be added in series with the surge generator to limit the current after suppressor operation to 3000 amps.

10.3.1 Fast-Front Impulse Suppression Tests—A 1.2/50-µs voltage impulse wave having a prospective crest voltage of 6-kV (5-kV/µs rate of rise) shall be used for the fast-front test. Five impulses of each polarity shall be applied to each set of terminals and the maximum peak voltage and response time obtained line to line and line to ground shall be recorded.

10.3.2 Slow-Front Impulse Suppression Tests—Slowfront tests shall be performed using a voltage impulse with a prospective crest of 4.5 kV and a wavefront (time from zero to crest) of 30 to 60 µs (approximately 150-V/µs rate of rise). The time to half-crest value on the tail of the prospective waveform should be at least twice the wavefront time. Five impulses of each polarity shall be applied to each set of terminals and the maximum voltage and response time obtained line-to-line and line-to-ground shall be recorded.

10.4 Voltage Protection Level Tests—The purpose of this test is to determine the voltage protection provided by the suppressor when passing a surge current. The voltage protection level shall be measured at the output terminals of the suppressor using 8/20-µs current impulse waveforms of both polarities applied to the input terminals. Three new specimens
(not previously surged) shall be subjected to five 1500-amp impulses of each polarity, followed by one 3000-amp surge of both polarities, applied between each set of input terminals and between each input terminal and ground. The time interval between current impulses shall not exceed 120 s. In the event that the input voltage developed by the current impulse generator exceeds 6 kV after the initial suppressor overshoot, the current impulse magnitude may be limited to a value which produces a 6-kV input voltage. The maximum value of line-to-line and line-to-ground voltage protection level at each current level shall be recorded and shall be less than the rated maximum suppression voltage rating. The range of voltage protection level values obtained with the series of 1500-amp impulses across the same set of terminals on any one unit shall not vary by more than 10 %.

10.5 Duty Cycle Tests—The duty cycle test establishes the ability of the suppressor to interrupt follow current successfully and repeatedly. Duty cycle tests shall be performed using one of the three suppressors previously used in the power frequency withstand tests. The suppressor shall be connected across a power supply within the tolerances of the nominal frequency. The power supply voltage, measured at the input terminals of the suppressor, shall be maintained as close as practicable to, but not less than, the rated maximum continuous operating voltage. The power supply shall have a short circuit capacity, measured at the suppressor input terminals, of at least 500 amps.

10.5.1 A series of ten 8/20-µs current impulse waves with a crest value of 1500 A and constant polarity shall be applied line-to-line with a time interval between surges of 50 to 60 s. The first surge shall be timed to occur 30° after voltage, zero in the power-frequency half-cycle of the same polarity as the impulse. The second impulse will be timed to occur at 60°, and the timing will be increased an additional 30° for each subsequent surge. A second series of ten current impulses shall be applied line to ground, with the first surge of this series occurring within 2 min of the tenth line-to-line surge. The leakage current before the first impulse and immediately following the last impulse of each series of impulses and the suppression voltage rating during each surge shall be measured. The measured leakage currents shall be less than 30 mA. The leakage current following the last (tenth) impulse shall not have increased by more than 10 % of the value obtained before testing. The measured suppression voltage rating shall be less than the rated voltage protection level. The range of voltage suppression values obtained shall not vary by more than 10 %. If the voltage produced at the suppressor input terminals exceeds 6 kV, the current impulse magnitude may be limited to a value which produces a 6-kV input voltage. Where a three-phase unit consists of three identical circuits, or the peak overvoltages and clamping overvoltages determined by the previous tests are within 10 % for all three phases, only one line-to-line and one line-to-ground test need be performed.

10.6 Life Cycle Tests—Life cycle tests establish the ability of the suppressor to retain its voltage limiting function following exposure to a large number of impulses equivalent to the suppressor’s life expectancy.

10.6.1 Voltage Impulses—Upon successful completion of the duty cycle tests, the suppressor selected for duty cycle testing shall have a series of 1000 voltage impulses with a 1.2/50-µs waveshape and 6-kV magnitude applied between one phase and ground (or between the same two phases if no ground connection is used). Power frequency voltage need not be applied during these tests. If the suppressor discharge current for these tests exceeds 750 A, a resistance of up to 8 Ω may be added in series with the surge generator to limit the current after suppressor operation to 750 A. Surges shall be applied at 5-s intervals. Measurements of the maximum peak voltage (voltage protection level plus peak overshoot) shall be taken for the first ten surges and for the last ten surges. The average of the maximum peak voltage for the first ten surges and for the last ten surges shall not vary by more than 10 %.

10.6.2 Current Impulses—Following the 1000 voltage impulses, 1000 current impulses with an 8/20-µs waveshape and 750-A magnitude shall be applied to the same set of terminals as were used for the 1000 voltage surges. If the voltage developed at the input terminals exceeds 6 kV, the current impulse magnitude may be limited to a value which produces an input voltage of 6 kV. Nominal frequency voltage shall be applied to the suppressor immediately before and for at least 10 s following application of the current impulse. Current surges shall be applied at 5-s intervals. The value of voltage protection level and the leakage current through the suppressor 10 s following the impulse shall be measured for the first ten surges and the last ten surges. The average of these two parameters for the first ten and last ten measurements shall not vary by more than 10 %.

10.7 Load Current and Voltage Drop Tests—For two-port surge suppressors, tests of the ampacity and voltage drop shall be conducted on one sample. A reduced voltage source may be used for the performance of these tests. For multi-phase suppressors, tests shall be performed using the assembled suppressor and the specified magnitude of test current shall be conducted through all phases simultaneously.

10.7.1 Rated Current and Voltage Drop—A current not less than the rated current of the suppressor shall be passed through the device (from “input” to “output” terminals) for a period of 1 h. The maximum voltage between corresponding input and output terminals shall be measured with rated current flowing through the suppressor at the end of the 1-h test period and shall not exceed 0.25 % of the nominal system voltage. The temperature rise of the suppressor case and any internal current-carrying components shall not exceed 20°C.

10.7.2 Inrush Current—A current equal to ten times rated current shall be passed through the suppressor (from input to output terminals) for ten cycles without loss of continuity (including interruption of fuses or other protective devices), causing the suppressor to shunt or limit current, or elevating the temperature of the suppressor or any of its current-carrying components by more than 20°C. Maximum continuous operating voltage shall be applied immediately following the application of the inrush current, and the measured leakage current shall be less than 30 mA.
11. Conformance and Production Tests

11.1 Conformance testing of a random sample may be requested by the purchaser to verify that selected performance characteristics demonstrated in the design tests have been maintained in the production suppressors supplied. These tests would not normally be performed unless specifically required. Production tests are routine tests performed on production units (or samples thereof) to ensure that basic safety requirements are met.

11.1.1 Conformance Tests—Conformance tests shall be performed only as required by the purchaser on a representative sample, selected at random, of the units supplied by the manufacturer. When required, testing shall be performed on the assembled suppressor. Sample size, testing required, and pass/fail criteria must all be specified by the purchaser. The following sample sizes and tests are suggested for conformance testing.

11.1.1.1 Sample Size:

<table>
<thead>
<tr>
<th>No. Supplied</th>
<th>Test Sample Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1–20</td>
<td>1</td>
</tr>
<tr>
<td>21–50</td>
<td>3</td>
</tr>
<tr>
<td>51–100</td>
<td>5</td>
</tr>
<tr>
<td>101 and above</td>
<td>5 % of total</td>
</tr>
</tbody>
</table>

11.1.1.2 Power Frequency Test—Each sample would be placed in an ambient temperature of at least 25°C, and the rated maximum continuous operating voltage would be applied for a period of two hours. Five cycles of 120 % of nominal system voltage for a period of 2 s, followed by 1 min at the maximum continuous operating voltage would then be applied. The leakage current at the beginning and end of this test would be measured to verify that it is less than the 30 mA rated leakage. Leakage current at the conclusion of the test should be less than 110 % of the initial leakage to demonstrate no permanent degradation. Additionally, the maximum continuous operating voltage should be applied between the line terminals and the ground connection for a period of 5 min. The leakage current after 5 min should be less than 30 mA and should not have increased by more than 10 % from the initial value at the beginning of the power frequency test.

11.1.1.3 Impulse Voltage Test—A single 1.2/50-µs voltage impulse wave having a prospective crest voltage of 6 kV would be applied between each pair of input line terminals and between each input line terminal and ground for each sample. The maximum peak voltage and response time measured for each impulse should not exceed the rated maximum values.

11.1.1.4 Impulse Current Test—Each sample would be connected across a power supply with the nominal system voltage and frequency. A single 8/20-µs current impulse with a peak amplitude of 750 A would be applied between one pair of input line terminals and between one line terminal and ground (selected at random) for each sample. If the voltage at the input terminals of the suppressor exceeds 6 kV, the amplitude of the current impulse could be reduced to that value which produces an input voltage equal to, but not less than, 6 kV. The voltage protection level and response time at the output terminals and the suppressor leakage current would be measured and should be less than the rated maximum values.

11.1.2 Production Tests:

11.1.2.1 Insulation Withstand—Each suppressor shall withstand, without electrical breakdown, a voltage applied between the line terminals and the grounded case (including accessible dead metal parts). The voltage applied shall be 1000–V ac plus twice rated maximum continuous operating voltage for a period of 1 minute or 1200–V ac plus 2.4 times rated maximum continuous operating voltage for a period of 1 s. This test shall be performed when the suppressor is fully assembled. Alternatively, where the test voltage can damage solid-state components, the insulating structures of the suppressor may be tested before assembly of internal components, provided the test is representative of the completed suppressor and a random sample representing at least 1 % and at least three suppressors from the day’s completed production are tested with any internal components which may be damaged by the test disconnected.

11.1.3 Ground Continuity—Each suppressor provided with a means for grounding (for example, ground terminal or pin) shall be tested using an ohmmeter, battery/buzzer circuit tester, or similar device to determine continuity between the grounding connection and all accessible dead metal parts.

12. Certification Requirements

12.1 When specified in the purchase order or contract, a producer’s or supplier’s certification shall be furnished to the purchaser that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

13. Marking Requirements

13.1 The product shall be labeled or tagged to show:

13.1.1 Manufacturer’s name, model, serial number, and country of origin,

13.1.2 Product name,

13.1.3 Surge suppressor class and type,

13.1.4 Nominal rated voltage, current, frequency, and service,

13.1.5 Voltage protection level (in volts or kilovolts) for each protective mode.

14. Packaging Requirements

14.1 Product shall be packaged, boxed, crated, or wrapped to provide suitable protection during shipment and storage.

15. Keywords

15.1 ac power; circuits; surge current; surge suppression; surge suppressors; voltage transients
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements are applicable to Navy procurements and shall apply only when specified by the purchaser in the contract or purchase order.

S1. Performance
S1.1 The surge suppressors shall meet the performance requirements of 7.1 except for voltage protection level at 480 V and minimum life which shall be in accordance with Table S1.1. In addition, the surge suppressors shall meet the performance requirements for minimum energy capability and minimum average power capability specified in Table S1.1.

S2. Life Cycle Test Requirements

<table>
<thead>
<tr>
<th>TABLE S1.1 Performance Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Voltage Protection Level at 480 V</td>
</tr>
<tr>
<td>Minimum life</td>
</tr>
<tr>
<td>Minimum energy capability</td>
</tr>
<tr>
<td>Minimum average power capability</td>
</tr>
</tbody>
</table>

S2.1 The surge suppressors shall meet all the life cycle requirements specified in 10.6 with the following exceptions:
S2.1.1 Number of applied voltage impulses as described in 10.6.1 shall be 2500. Surges shall be applied at 12-s intervals.
S2.1.2 Number of applied current impulses as described in 10.6.2 shall be 2500. Surges shall be applied at 12-s intervals.

S3. Testing—The supplier is responsible for the performance of all testing and inspections. Except as otherwise specified, the supplier may use his own facilities or any commercial laboratory acceptable to the Government. The Government may reserve the right to perform any of the testing or inspections set forth in the specification requirements. This testing shall assure qualification on a one-time basis unless the manufacturer makes a significant change in materials or process.

APPENDIX

X1. ADDITIONAL INFORMATION ON DESIGN AND PERFORMANCE CONSIDERATIONS

X1.1 Shipboard Electrical Systems Environment:
X1.1.1 Transient voltage surge suppressors (TVSS) devices work better and can more effectively shunt damaging transient overvoltages and current pulses to electronic equipment, if system grounding is done properly and has good integrity. Therein lies the major problem with TVSS devices for shipboard use. Unlike industrial or commercial electrical systems which have an ac supply ground and an equipment ground, most shipboard electrical systems are “ungrounded.” Without a system ground (normally referred to as the neutral or common), then shipboard TVSS devices have protective modes that are limited to line-to-line and/or line-to-ground shunting of transients. Equipment (safety) grounds are achieved by proper mounting of equipment to the ship’s metal hull or structure or installation of grounding straps between the hull and isolated equipment. The effectiveness of shipboard TVSS will be highly dependent on the equipment grounding techniques.

X1.2 Single Component Versus Hybrid Transient Voltage Surge Suppressors:
X1.2.1 Activated by transient voltage and current, a TVSS component redirects or shunts a portion of the transient current through the device and away from the load. A number of TVSS components are available with each having distinct advantages and disadvantages. These components consist of two basic types of protector: clamps and crowbars. Clamps (metal-oxide varistors and silicon avalanche suppressors) simply limit, while crowbars (gas tubes and carbon-block arrestors) exhibit steep negative resistance characteristics that result in voltage protection levels well below their striking potential.

X1.2.2 Hybrid transient voltage surge suppressors are designed to take advantage of several different types of components thereby enhancing overall performance and reliability. Hybrids usually incorporate a high energy capable, primary suppression section and tighter clamping, lower energy section. A hybrid design appears simple, however the proper component selection by the manufacturer is critical so that they function together as a coordinated system. A properly designed hybrid TVSS will vastly outperform any single component suppressor.

X1.3 Series Versus Parallel Devices:
X1.3.1 Surge suppressor components are inherently parallel or “across the line” components making them insensitive to load currents. However, because any impedance between the surge suppressor component and the transient-carrying line greatly reduces their effectiveness, lead length is an important consideration. The ideal one-port (parallel or shunt-connected) surge suppressor configuration is one with leads as short as possible. Longer leads, especially those excessive in length, may entirely negate the capability of the surge suppressor. Unfortunately, most transient voltage suppressors are parallel in design and require long wire-up leads.

X1.3.2 Series-connected (two-port) TVSS systems require load current sensitivity because all load currents pass through them. However, leads may be minimized in two-port designs, thereby significantly enhancing performance. Additionally, most two-port surge suppressors offer hybrid designs that incorporate multiple components and a coupling inductor.
X1.4 Envelope Clamping Versus Sine Wave Clamping:

X1.4.1 There are two main types of surge suppressors, envelope or threshold clamping devices and sine-wave clamping devices. Envelope devices, which represents the majority of surge suppressors available today, use only solid-state protection components such as metal oxide varistors (MOVs) or silicon avalanche diodes and operate by limiting or clamping the voltage across their terminals. This voltage protection level depends on the transient current and waveshape and must be chosen high enough not to interfere with the normal operation of the protected line.

X1.4.2 Envelope clamping devices are very effective at preventing transient damage from occurring to simple devices such as motors or power supplies, where insulation breakdown from high voltage would occur. They are not effective at keeping transient energy from low-voltage supplies to sensitive electronics or microprocessors.

X1.4.3 Sine-wave clamping suppressors consist of complex hybrid filter/suppressor circuits that effectively attenuates high frequency transients at whatever phase angle it occurs. Sine-wave clamping devices create lower clamping levels ensuring that any residual transient which propagates through low voltage power supplies is too small to cause circuit damage or logic disruption at the circuit board level.

X1.4.4 Although more costly than single-component or envelope (threshold clamping) devices, the use of hybrid surge suppressors that offer high-energy suppression, high-speed suppression and a EMI/RFI filter be adopted. Such devices should be installed at power distribution panels and critical electronic equipment and computers.

X1.5 Networking Surge Suppressors:

X1.5.1 Networking surge suppressors gives superior performance and reduced costs over the application of single devices. Suppression networks are built by distribution of components at more that one point within as electrical system. Networks do more than just protect more loads at more places; they actually improve the performance of individual components, by taking advantage of the wire’s self-inductance between surge suppressors. Suppressor networks result in superior performance at a lower cost since the very best single point devices are no longer needed for effective protection.

X1.5.2 Networked surge suppressors reduce the amplitude of the transient step by step. The relationship of voltage protection level to current for suppression devices like MOVs is that the lower the current the lower the voltage protection level and, therefore the lower the residual voltage getting through to the load you are trying to protect. Transients act like waves in a transmission line. When the wave encounters a change of impedance (which occurs with the introduction of suppression component such as an MOV or silicon avalanche diode), then a portion of the transient is reflected (bounces back) in the opposite direction with an opposite polarity. That portion of energy which finds its way in between two suppression devices separated by (wire) inductance, bounces back and forth until it is dissipated or escapes into other forms of energy.

X1.6 Safety Features:

X1.6.1 There is a fire hazard with surge suppressors. Surge suppressors can and do catch fire. Suppressors used to protect sensitive electronic equipment in home, office, industry, Naval and marine against transient voltages on ac circuits have failed in service, some overheating seriously, melting and even catching on fire. The theoretical cause has been debated and fire hazard tests proposed, however the most practical solution is to include provisions in the equipment design to preclude the devices catching fire. Those recommended for consideration by the purchaser would include:

X1.6.1.1 Enclosure shall be metallic.

X1.6.1.2 Two-port devices shall include a circuit breaker that interrupts all phases (and neutral where applicable) of the supply circuit.

X1.6.1.3 Thermal protection of TVSS shall interrupt supply circuit for overtemperature condition.

X1.6.1.4 Fail open circuit that automatically shuts off power to connected equipment in the event of a suppression component failure and protects equipment from being exposed to unfiltered “raw” power.

X1.6.2 Thermal failure modes of gapless, varistor-based surge suppressors is considered significantly more likely than failure to a surge suppressor during a large, single energy transient. Thermal failure involves thermal runaway from one of three sets of circumstances:

X1.6.2.1 Following a large transient that elevated the temperature of MOV beyond point of recoverable thermal equilibrium.

X1.6.2.2 During an extended temporary overvoltage (sometimes referred to as a “voltage swell”).

X1.6.2.3 At the end of the life of a device previously exposed to repetitive temporary overvoltages or surges, when the rated number and magnitude of pulses for that device has been exceeded and the standby current has slowly increased to a point where thermal runaway develops.

X1.6.3 Surge suppressors, as recommended in this standard, should include a thermal cutoff device (in addition to an overcurrent protective device) that will sense the varistor temperature and interrupt the supply source during the initial part of the thermal runaway. In reality, the thermal failure modes of X1.6.2.1 and X1.6.2.2 may happen too fast for a cut-off device to act before terminal thermal runaway. The failure mode defined in X1.6.2.3 is the most preventable by a closely coupled cutoff device.
Standard Specification for Angle Style, Pressure Relief Valves for Steam, Gas, and Liquid Services

This standard is issued under the fixed designation F 1508; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers spring-loaded, angle style, pressure relief valves for steam, gas, and liquid system applications (excluding boiler safety and hydraulic system relief valves).

2. Referenced Documents

2.1 ASTM Standards: 2
A 105/A 105M Specification for Carbon Steel Forgings for Piping Applications
A 125 Specification for Steel Springs, Helical, Heat-Treated

803-1385946 Unions, Bronze Silver Brazing, WOG, for UT Inspection

### 3. Terminology

#### 3.1 Definitions:

3.1.1 **accumulation**—the increase in static pressure above the set pressure during discharge through the valve, when the valve passes the rated flow. Accumulation is expressed in pound-force per square inch or as a percent of the set pressure.

3.1.2 **accumulation pressure**—the set pressure plus the accumulation. Accumulation pressure is expressed in pound-force per square inch gage.

3.1.3 **blowdown**—the difference between the set pressure and the reseating pressure. Blowdown is expressed in pound-force per square inch or a percent of the set pressure. The accumulation and blowdown establish the operating band of the pressure relief valve at a particular set pressure.

3.1.4 **blowdown pressure**—the set pressure minus the blowdown. Blowdown pressure is expressed in pound-force per square inch gage.

3.1.5 **built-up backpressure**—the static discharge pressure at the outlet of a pressure relief valve caused by the pressure drop in the discharge piping while the valve is discharging.

3.1.6 **gagging device**—a device, normally a screw (also called test gag), used to prevent the pressure relief valve from opening during a hydrostatic pressure test of the equipment on which it is installed.

3.1.7 **inlet piping**—when used in this specification, refers to all piping and fittings between the source and the inlet connection to the pressure relief valve.

3.1.8 **instability (chatter, flutter)**—an unstable operation of the pressure relief valve characterized by rapid seating and unseating of the disk during discharge. This hammering of the disk on the seat can cause high loading forces, which can lead to damage and rapid failure of the seating and sliding surfaces.

3.1.9 **maximum system operating pressure**—the highest pressure that can exist in a system, vessel, or component under normal (noncasualty) operating conditions. This is a normal (noncasualty) pressure that the pressure relief valve is not intended to protect against. This pressure can be the result of influences such as pump or compressor shutoff pressure, pressure regulating valve lockup (no flow) pressure, and so forth.

3.1.10 **opening pressure**—the value of increasing inlet static pressure of a pressure relief valve at which there is a measurable lift, or at which the discharge becomes continuous by seeing, feeling, or hearing.

3.1.11 **outlet piping (or discharge piping)**—when used in this specification, refers to all piping and fittings between the pressure relief valve outlet connection and the main, tank, or atmosphere to which the pressure relief valve relieves.

3.1.12 **popping pressure**—the value of increasing inlet static pressure at which the disk moves in the opening direction at a faster rate as compared with the corresponding movement at higher or lower pressures. It generally applies to valves with compressible fluid service such as steam, gas, and so forth.

3.1.13 **pressure relief valve**—an automatic pressure relieving device actuated by the static pressure upstream of the valve and characterized by either rapid opening (pop action for gas, vapor, or steam) or gradual opening (for liquids).

3.1.14 **primary and secondary pressure zones of pressure relief valve**—primary pressure zone refers to all portions of the pressure-containing envelope subject to inlet pressure; secondary pressure zone refers to all portions of the pressure-containing envelope subject to outlet or discharge pressure (includes spring housing of nonvented valves).

3.1.15 **relieving capacity (also called flow capacity)**—the pressure relief valve is defined as the quantity of pressure medium relieving through the pressure relief valve at the accumulation pressure, such as pound per hour of steam, gallon per minute of water at 70°F, or SCFM (standard cubic feet per minute at 60°F and 14.7 psia) of air, as applicable.

3.1.16 **set pressure**—the value of increasing inlet static pressure at which a pressure relief valve displays one of the operational characteristics as defined under opening pressure, or start-to-lease pressure. Set pressure is expressed in pound-force per square inch gage.

3.1.17 **set pressure range**—the range over which the set pressure can be adjusted with the installed spring.

3.1.18 **set pressure tolerance**—the permissible plus or minus deviation from the specified set pressure. Set pressure

---

*Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.*
tolerance is expressed in pound-force per square inch or as a percent of the set pressure.

3.1.19 source—when used in this specification, refers to the pressure container being protected from overpressure by the pressure relief valve, for example, piping main, pressure vessel or tank, casing, and so forth.

3.1.20 start-to-leak pressure—the value of increasing inlet static pressure at which the first bubble occurs when a pressure relief valve for compressible fluid service of the resilient disk design is tested by means of air under a specified water seal on the outlet.

3.1.21 superimposed backpressure—the static pressure on the discharge side of a pressure relief valve prior to the opening of the pressure relief valve. This pressure exists where the pressure relief valve discharges into a common pipeline shared with other pressure sources such as pressure relief valves, or into a pressurized or closed system. This pressure may have the effect of changing the set pressure of the pressure relief valve.

3.1.22 top-guided valve—this type of valve has all the guiding, rubbing, or contacting surfaces on the discharge side of the seat.

4. Classification

4.1 Pressure relief valves shall be of the following types and material grades:

4.1.1 Type I—For Steam Service:

4.1.1.1 Grade A—Alloy steel construction (for steam service temperatures up to 1000°F) (see Table 8).

4.1.1.2 Grade B—Carbon steel construction (for steam service temperatures up to 775°F) (see Table 8).

4.1.2 Type II—For Air, Gas Service:

4.1.2.1 Grade C—Bronze or stainless steel construction (for air, gas service excluding oxygen) (see Table 9).

4.1.2.2 Grade D—Ni-Cu alloy construction (for oxygen) (see Table 9).

4.1.3 Type III—For Liquid Service (except hydraulic oil):

4.1.3.1 Grade E—Ferrous construction (for noncorrosive liquids, such as fuel oil, water, steam condensate, and so forth) (see Table 9).

4.1.3.2 Grade F—Nonferrous construction (for corrosive liquids, such as seawater, and so forth) (see Table 9).

5. Ordering Information

5.1 Ordering documentation for valves under this specification shall include the following information, as required, to describe the equipment adequately.

5.1.1 ASTM designation and year of issue.

5.1.2 Valve specification code (see 6.2).

5.1.3 Quantity of valves.

5.1.4 Maximum inlet temperature.

5.1.5 Set pressure.

5.1.6 Required relieving capacity (flow) at the accumulation pressure.

5.1.7 Installation limitations data, if different than specified in 7.9.

5.1.8 Blowdown limits, if different than specified in 7.7.

5.1.9 Envelope dimensions, if not covered in Table 13 and Table 14.

5.1.10 Supplementary requirements, if any (see S1 through S5).

6. Valve Coding and Construction

6.1 Valves shall incorporate the design features specified in 6.2 and 6.3.

6.2 Valve Specification Coding—Basic valve design features shall be specified and recorded using the following valve coding system. The valve specification code contains nine fields of information, which describe the construction features of the valve. Each of these nine fields is further assigned their respective codes in accordance with Tables 1-7.

6.3 Construction—Valve construction shall be in accordance with the requirements specified in 6.3.1-6.3.19.

6.3.1 The materials of construction for various valve components are detailed in Table 8 for Type I valves and Table 9 for Types II and III valves.

6.3.2 General Requirements—The valve shall be self-contained, single-seated, and spring-loaded where the inlet pressure is directly sensed under the spring-loaded disk. The valve shall incorporate only a single inlet and a single outlet connection.

6.3.3 Pressure-Temperature Ratings—The pressure-temperature ratings of a pressure relief valve consist of ratings for the primary and secondary pressure zones.

6.3.3.1 Pressure-Temperature Rating of the Primary Pressure Zone—This shall correspond to the rating of the inlet end connection, and is given in Table 10.

6.3.3.2 Pressure-Temperature Rating of the Secondary Pressure Zone—The secondary pressure zone shall withstand the higher of the following:

1. 150% of maximum backpressure buildup specified in 7.9.

2. 600 psig (for Type II, Grade C and Type III, Grade F valves only).

3. ANSI B16.34, Class 150 pressure rating (for Type I, Grades A and B and Type III, Grade E valves only).

TABLE 3 End Connection Codes for Valve Inlet and Outlet Ports

**Note 1**—Unless otherwise specified in the purchase order (Code W), all ANSI flanges shall have raised faces.

**Note 2**—Unless otherwise specified in the purchased order (Code W), all Navy flanges shall be plain and without preinserted rings.

6.3.4 Body Construction—The valve shall be of the angle-body design. It shall be constructed so that the seat will not become distorted relative to the disk, and valve operation is not adversely affected by internal pressure and temperature.

6.3.5 Bonnet Construction (Spring Housing):

6.3.5.1 For Type I valves, the bonnet shall be attached to the body with bolted flanges. Type I, Grade A valves must have exposed spring bonnets—the discharge flow released through the open bonnet shall be minimal. For Type II and Type III valves, the bonnet shall be attached to the body with bolted flanges, or a threaded union connection.

6.3.5.2 For pressure-tight (nonvented) bonnet construction valves (for air/gas and liquid applications), there shall be no discharge of pressure medium into the atmosphere from the bonnet or from the body-to-bonnet joint.

6.3.5.3 Vented-bonnet construction valves shall incorporate a threaded vent hole in the bonnet for the discharge of pressure medium into the atmosphere. The discharge flow released through the vent hole shall be minimal. The vent hole shall be capable of attaching a pressure-tight MS straight-threaded tube fitting to divert the pressure relief to a distant location. The nominal tube fitting size shall be in accordance with Table 11.

The vent hole shall be in accordance with MS 16142. Valves shall be furnished with a vent plug in accordance with MS 51840 to keep the dirt away and to allow hydro testing. A warning tag instructing the mandatory removal of the vent plug after valve installation must also be attached to the valve vent plug.

6.3.5.4 There shall be one bonnet for each valve body of a particular nominal inlet size and pressure-temperature rating. It shall be capable of housing any of the springs required to span the applicable set pressure ranges.

6.3.6 Internal Trim:

6.3.6.1 For Type I valves, valves shall be provided with a threaded seat ring, which shall be welded or nickel-brazed circumferentially to the body. The valve body shall have sufficient metal at the seat section to permit installation of a separate seat ring, if required as a service repair. When the seat ring is a part of the inlet flange raised face, such as in full nozzle valves, no welding or brazing is required.

6.3.6.2 For Type II and III valves, the valve shall have a replaceable seat ring. The seat ring shall be either thread-in or retained by a cage construction and shall be easily replaceable, using hand tools, after extended service.

6.3.6.3 The valve disk to valve seat sealing must be metal to metal for Type I valves and metal to nonmetal for Type II and Type III valves.

6.3.6.4 The disk or the disk holder assembly shall be top-guided. Bottom-guided valves (also known as wing-guided valves), or other construction valves where all or part of the guiding surfaces are under the disk, are not permitted. Guiding surfaces (bushings and posts) shall have the proper hardness, finish, concentricity, parallelism, clearances, length, and rigidity to prevent binding or seizing and to ensure proper seating under all operating conditions. These alignment requirements shall be maintained with interchangeable parts and under any tolerance stackup.

6.3.7 Interchangeability—In no case shall the parts be physically interchangeable in a valve unless such parts are also interchangeable with regard to function, performance, and strength. Where machining is required after installation of a seat ring or guide to maintain critical concentricity or alignment dimensions, detailed instructions must be provided with each repair part.

6.3.8 Spring—The spring shall be designed so that the full lift spring compression shall be no greater than 80% of the nominal solid deflection. The permanent set of the spring (defined as the difference between the free height and height measured 10 min after the spring has been compressed solid.
four times at room temperature) shall not exceed 0.5 % of the free height. Spring ends shall be squared and ground.

6.3.9 Threads—Threads shall conform to ANSI B1.1. Provisions shall be incorporated to prevent the accidental loosening of threaded parts. Pipe threads and lock-washers shall not be used.

6.3.10 Bearing Surfaces—Nut- and bolt-bearing surfaces and their respective mating surfaces on the valves shall be machine finished.

6.3.11 Stem Packing—A stuffing box, O-rings, or any other nonmetallic materials shall not be permitted on the stem/disk guiding surfaces.

6.3.12 Hand-Lifting Device—When specified (see 6.2), valves shall be provided with a hand-lifting device so that they may be operated by hand for testing purposes with an inlet pressure of 75 % of the set pressure. Type I and Type III valves must be furnished with a hand-lifting device. The necessary lever or tool shall be furnished as part of the valve. For valves requiring pressure-tight (nonvented) bonnets, a stuffing box or a seal on the shaft of the hand-lifting device which will have no effect on the valve set pressure and the valve lift, shall be required.

6.3.13 Gagging Device—When specified for system test purposes (see 6.2), a gagging device shall be supplied with the valve. Valves shall be constructed to be gagged without alteration of the set point. The gagging screw shall be provided with a knurled or wing nut-type head to discourage the use of

6.3.14 Accessibility—Valves shall permit adjustment and repair without removal from the line.

6.3.15 Valve Adjustment:

6.3.15.1 Means shall be provided for adjusting the set pressure setting with the valve under pressure. The adjusting screw shall have right-hand threads so that clockwise rotation increases the set pressure. The adjusting device shall be provided with a locknut and cap, or other suitable means, to prevent accidental change of adjustment.

6.3.15.2 Valves shall have adjustable blowdown using blowdown ring(s). Positive means shall be used to lock the adjusting ring(s) in place by use of adjustable ring pins(s). The pin(s) shall be installed through the penetration hole in the lower valve body.

6.3.16 Valve Envelope Dimensions—Unless otherwise specified in the ordering data, valves must meet the overall envelope dimensions shown in Table 12 for Type I valves and Table 13 for Types II and III valves.

6.3.17 Cleaning—Type II, Grade D valve parts (for oxygen service) shall be cleaned in accordance with MIL-STD-1330 and maintained oxygen clean.

6.3.18 Sealing—Means shall be provided in the design of all valves for sealing all external adjustments such as set pressure. Seals shall be installed by the manufacturer or assembler at the time of initial shipment and after field adjustment or repair of the valves by either the manufacturer, his authorized representative repairer, or the user. Seals shall be installed in such a manner as to prevent changing the adjustment without breaking the seal and, in addition, shall serve as a means of identifying the manufacturer, assembler, repairer, or user making the adjustment.

6.3.19 Asbestos material is not permitted in the valve construction.

7. Performance Requirements

7.1 All valves shall meet the requirements of 7.2-7.10.

7.2 Range of Set Pressure Adjustment—For Type I and Type III valves, the set pressure shall be adjustable over a range of at least ±10% of the specified set pressure, for set pressures up to 250 psig; and when the specified set pressure exceeds 250 psig, this range shall be ±5%. For Type II valves, the set pressure shall be adjustable over the set pressure range specified in Table 14. If required, more than one spring may be used to accomplish this.

7.3 Performance Testing:

7.3.1 Type I and Type III valves of non-automotive classification shall be tested to the requirements of 7.3.2.

7.3.2 Type II valves of non-automotive classification shall be tested to the requirements of 7.3.3 and 7.3.4, if applicable.

### TABLE 12 Valve Envelope Dimensions (Inches) for Type I Valves (See Fig. 1)

**Note 1**—Variations for A and B dimensions are ±0.06 in. C is the maximum dimension shown.

**Note 2**—Dimensions not shown in the table shall be in accordance with API 526. If dimensions are not shown in Table 12, or are not listed in API 526, they should be agreed upon between the buyer and the valve supplier.

7.3 Operation—Valves shall operate without instability throughout their full range of capacity. Types I and II valves shall open with a clear, sharp pop. Valve closure shall be clear and sharp when the inlet pressure is reduced to the blowdown pressure. Type III valves shall open/close gradually, without instability, in response to the increase/decrease in pressure over the opening pressure.

7.4 Hydrostatic Shell Test Pressure—The valve shall show no signs of external leakage, permanent deformation, or structural failure when subjected to the hydrostatic shell test pressure specified in 8.2.

7.5 Set Pressure Tolerance—For all types of valves, the set pressure tolerance, plus or minus, shall not exceed the following: 2 psi for set pressures up to 70 psig, 3 % for set pressures over 70 psig up to 300 psig, 10 psi for set pressures over 300 psig up to 1000 psig, and 2 % for set pressures over 1000 psig.

7.6 Accumulation—Valves shall be sized to pass the specified flow (see 5.1.6) without permitting the inlet pressure (source static pressure) to rise beyond the accumulation pressure. The accumulation (overpressure) shall not exceed 10 % of set pressure, or 3 psi, whichever is greater. The valve shall show no signs of instability.

7.7 Blowdown Limits—Unless otherwise specified in the ordering data (see 5.1.8), valves shall operate satisfactorily with the following blowdown pressure setting:

7.7.1 For Type I and Type II valves, the maximum blowdown limit shall be 3 psi or 7 % of the set pressure, whichever is greater.

7.7.2 For Type III valves, the maximum blowdown limit shall not exceed 15 % of the set pressure or 3 psi, whichever is greater.

7.8 Seat Tightness—With an inlet pressure at or above the minimum allowable blowdown pressure setting, the valve shall seat tightly. No through seat leakage under this condition shall be allowed (see Table 15).

TABLE 13 Valve Envelope Dimensions (Inches) for Type II, Grade C, and Type III Valves (see Fig. 1) (Without Tailpieces and Nuts)

NOTE 1—Variations for A and B dimensions are ±0.06 in. C is the maximum dimension shown.

NOTE 2—Dimensions do not include length of nut or tailpiece.

NOTE 3—Dimensions not shown in the table should be agreed upon between the buyer and the valve supplier.

7.7.1 For Type I and Type II valves, the maximum blowdown limit shall be 3 psi or 7 % of the set pressure, whichever is greater.

7.7.2 For Type III valves, the maximum blowdown limit shall not exceed 15 % of the set pressure or 3 psi, whichever is greater.

7.8 Seat Tightness—With an inlet pressure at or above the minimum allowable blowdown pressure setting, the valve shall seat tightly. No through seat leakage under this condition shall be allowed (see Table 15).

7.3 Operation—Valves shall operate without instability throughout their full range of capacity. Types I and II valves shall open with a clear, sharp pop. Valve closure shall be clear and sharp when the inlet pressure is reduced to the blowdown pressure. Type III valves shall open/close gradually, without instability, in response to the increase/decrease in pressure over the opening pressure.

7.4 Hydrostatic Shell Test Pressure—The valve shall show no signs of external leakage, permanent deformation, or structural failure when subjected to the hydrostatic shell test pressure specified in 8.2.

7.5 Set Pressure Tolerance—For all types of valves, the set pressure tolerance, plus or minus, shall not exceed the following: 2 psi for set pressures up to 70 psig, 3 % for set pressures over 70 psig up to 300 psig, 10 psi for set pressures over 300 psig up to 1000 psig, and 2 % for set pressures over 1000 psig.

7.6 Accumulation—Valves shall be sized to pass the specified flow (see 5.1.6) without permitting the inlet pressure (source static pressure) to rise beyond the accumulation pressure. The accumulation (overpressure) shall not exceed 10 % of set pressure, or 3 psi, whichever is greater. The valve shall show no signs of instability.

7.7 Blowdown Limits—Unless otherwise specified in the ordering data (see 5.1.8), valves shall operate satisfactorily with the following blowdown pressure setting:

7.7.1 For Type I and Type II valves, the maximum blowdown limit shall be 3 psi or 7 % of the set pressure, whichever is greater.

7.7.2 For Type III valves, the maximum blowdown limit shall not exceed 15 % of the set pressure or 3 psi, whichever is greater.

7.8 Seat Tightness—With an inlet pressure at or above the minimum allowable blowdown pressure setting, the valve shall seat tightly. No through seat leakage under this condition shall be allowed (see Table 15).
7.9 Installation Limitation—Valve operation shall not be adversely affected (loss of capacity or instability) by an inlet piping pressure loss of up to 25 % of the relief valve maximum permitted blowdown or an outlet piping break-pressure buildup of up to 10 % of the set pressure, or both. Where the installation will subject the valve to more severe piping restrictions, this information shall be noted in the ordering data (see 5.1.7).

7.10 Effective Discharge Area \((A)\)—Valves shall meet the effective discharge areas \((A)\) specified in Table 16 based on flow tests and neglecting any inlet/outlet losses (in accordance with API Standard RP520, Part 1, Appendix C).

Note 1.—To calculate the required effective discharge area for a given relief capacity requirement, see the following examples for steam, gas, and liquid services (for additional details, refer to API RP520, Part 1, Appendix C).

Note 2.—The formulae shown in Examples 1, 2, and 3 are for valves with vented/exposed spring construction bonnets. Nonvented bonnet valves generally have much lower capacity and the valve manufacturer should be consulted to obtain their capacities. Also, the calculated effective discharge area does not include impact as a result of installation limitation in accordance with 7.9.

Example 1, Steam Service:
Given: Flow medium = saturated steam
Upstream pressure = 100 psig
Accumulation = 10 %
Required flow through valve = 1774 lb/h
Calculate: \(A\) (effective discharge area of valve)

For steam service, use formula "C-10" in API RP520, Part 1, Appendix C

\[
A = \frac{W}{50P_1K_{SH}} \tag{1}
\]

where:
\(A\) = effective discharge area of valve, in.\(^2\);
\(W\) = required flow through valve, lb/h;
\(P_1\) = upstream relieving pressure, psia = 124.7 at 100-psig set pressure; and
\(K_{SH}\) = correction factor as a result of amount of superheat in steam = 1.0 for saturated steam.

Then substituting these values in Eq 1,

\[
A = \frac{1774}{50 \times 124.7 \times 1.0} = 0.285 \text{ in.}^2 \tag{2}
\]

Example 2, Air Service:
Given: Flow medium = air
Upstream pressure = 100 psig
Accumulation = 10 %
Temperature = 60°F
Required flow through valve = 556 SCFM
Calculate: \(A\) (effective discharge area of valve)

For air service, use formula "C-3" in API RP520, Part 1, Appendix C

\[
A = \frac{1774}{50 \times 124.7 \times 1.0} = 0.285 \text{ in.}^2 \tag{2}
\]
8.3 Set Pressure, Blowdown, and Seat Tightness Test—Inlet pressure (see Table 15 for test medium) shall be increased until the valve opens. Inlet pressure shall be reduced until the valve reseats. Leakage shall be checked over a 3-min period at an inlet pressure equal to the minimum allowable blowdown pressure setting. There shall be no damage to seating surfaces and no instability (chatter). The valve shall conform to the requirements in accordance with 7.5, 7.7, and 7.8.

9. Marking

9.1 Each valve shall be plainly and permanently marked by the manufacturer with the required data in such a way that the marking will not be obliterated in service. The marking may be placed on the valve or on a corrosion-resistant plate permanently attached to the valve. The following data is required:

9.1.1 Name of the manufacturer,
9.1.2 Manufacturer’s design or type number,
9.1.3 Valve specification code,
9.1.4 Size _____in. (nominal pipe size of the valve inlet),
9.1.5 Set pressure _____psi,
9.1.6 Rated relieving capacity (as applicable): Note 3—The information listed in 9.1.5 and 9.1.6 must be placed on a corrosion-resistant plate permanently attached to the valve.

9.1.6.1 Pounds per hour of saturated steam at an overpressure of 10 % of set pressure or 3 psi, whichever is greater, for valves used in steam service; or
9.1.6.2 Gallon per minute of water at 70°F at an overpressure of 10 % of set pressure or 3 psi, whichever is greater, for valves used in water service; or
9.1.6.3 SCFM (standard cubic feet per minute at 60°F and 14.7 psia) of air at an overpressure of 10 % of set pressure or 3 psi, whichever is greater, for valves used in air or gas service.
9.1.6.4 For Type I valves (where the outlet size is larger than the inlet size), the effective orifice area letter designation in accordance with API 526 must be stamped.
9.1.7 Service fluid (line medium),
9.1.8 Manufacturers’ serial number identifying the valve. The serial number should be stamped on the body and placed adjacent to the nameplate,
9.1.9 Range of set pressure adjustment.
9.2 All connections (inlet, outlet, drain, and so forth) shall be permanently marked to aid in correct installation of the pressure relief valve.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system which will ensure that all the requirements of this specification are satisfied. This system shall also ensure that all valves will perform in a similar manner to those representative valves subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the system the manufacturer will use shall be available for review and acceptance by the purchaser or his designee.

Note 4—If supplementary requirement S4 is specified in 5.1.10, an
10.3 The purchaser or his designee reserves the right to witness the production tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

**SUPPLEMENTARY REQUIREMENTS**

One or more of the following supplementary requirements S1, S2, S3, S4, or S5 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing between the manufacturer and the purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

**S1. Examinations**

S1.1 Examination of Materials—Materials used in the manufacture of valves shall be examined to determine conformance to 6.3.1. Contracting agencies or their representatives shall normally accept certifications that the material complies with the specification; however, testing to demonstrate compliance may be required.

S1.2 Visual and Dimensional Examination—Visual and dimensional examination on sample valves shall be conducted to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

S1.3 Nondestructive Tests—When nondestructive tests such as radiography, magnetic particle, or dye penetrant tests are required, they shall be specified in the ordering information (see 5.1.10).

**S2. Initial Qualification Testing**

S2.1 Rated Relieving Capacity Test—The valve-rated relieving capacity data shall be obtained and certified by the manufacturer by following the procedures outlined in Section VIII of the ASME Boiler and Pressure Vessel Code.

S2.2 Endurance Test—The valve shall be cycled with the pressurized test medium (see Table 15 for the test medium) 50 times. After each ten cycles, the set pressure and the leakage shall be checked. Valve shall conform to the requirements specified in 7.5 and 7.8. There shall be no signs of instability or damage to the seating surface.

S2.3 Mechanical Shock Test—The valve shall be tested in accordance with the requirements of Grade A, Class I of MIL-S-901. The valve shall be pressurized during test. There shall be no structural damage or degradation to performance capability.

S2.4 Vibration Test—The valve shall be tested in accordance with Type I of MIL-STD-167-1. At frequencies up to and including 33 Hz (unless otherwise specified in the ordering information, see Section 5), there shall be no structural damage or degradation to performance.

S2.5 Stuck Valve Test—With the valve set at the specified set pressure, and not subjected to any inlet pressure, the valve shall be left in the closed position for a minimum of 72 h. After this 72-h period, the inlet pressure (see Table 15 for test medium) shall be increased until the valve opens. Valve shall conform to the requirement specified in 7.5.

**S3. Valve Testing With Imposed Installation Limitations**

S3.1 The test set up shall impose an inlet piping pressure loss of 25% of the blowdown (or the maximum inlet piping pressure loss, when specified in 5.1.7), and an outlet piping pressure buildup of 10% of set pressure (or the maximum outlet piping pressure buildup, when specified in 5.1.7). Tests outlined in 8.3 and S2.1 should be conducted to verify conformance to 7.5-7.9.

**S4. Quality Assurance**

S4.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S4.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S4.3 Organization—An organization chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility, the authority, and the organizational freedom to identify quality control problems, and to initiate, recommend, and provide solutions.

S4.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S4.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S4.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.

S4.7 Material Control—The manufacturer shall include a system for material control which ensures that the material
received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system that identifies inspection status of material throughout all stages of manufacture. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S4.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S4.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.

S4.10 Welding—The quality control system shall include provisions for ensuring that welding is in accordance with specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.

S4.11 Nondestructive Examination—Provisions shall be made to use nondestructive examination as necessary to ensure that material and components comply with the specified requirements. Nondestructive examination operations shall be conducted by a recognized national body, and their qualification records shall be made available to the inspection authority if required.

S4.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in accordance with the specified requirements.

S4.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.

S4.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during all stages of manufacture and shall be able to distinguish between inspected and noninspected material.

S4.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring, and test equipment to be used in verifying accordance with the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S4.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S4.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S4.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

S5. High-Integrity Body Valves

S5.1 These valves shall meet all the requirements of Type III construction. In addition, they shall have pressure-tight bonnet construction and not have any penetrations in the valve body. An accumulation of 25 % is permissible. The maximum blowdown limit shall not exceed 15 % of the set pressure or 8 psi, whichever is greater. These valves need not have the adjustable blowdown feature.

APPENDIX

X1. GUIDELINES FOR SELECTION AND INSTALLATION OF PRESSURE RELIEF VALVES

X1.1 Scope—This appendix provides general guidance for the selection and installation of pressure relief valves for shipboard use, and therefore, its use does not in any way relieve a shipbuilder of the final responsibility in the selection and installation of pressure relief valves. This appendix does not apply to boiler safety valves or hydraulic system relief valves.

X1.2 General—A properly designed, applied, and installed pressure relief valve will begin to lift at a definite pressure (set pressure), attain rated lift at a definite overpressure (accumulation pressure), and subsequently reseat at a definite lower pressure (blowdown pressure) once the overpressure condition at the source is corrected. For the pressure relief valve to function properly, the pressure at the source and the pressure differential that tends to hold the pressure relief valve disk in the open position must be the same (within certain limits) under all flowing conditions. Unstable operation (chatter) of a properly designed but improperly installed relief valve will occur when the pressure differential across the valve is not
maintained during flowing conditions. This can result from any one of the following (or a combination of the following) causes:

**X1.2.1 Restricted Inlet Piping**—The inlet piping restricts flow to the pressure relief valve, and sufficient flow from the source to the pressure relief valve cannot be sustained.

**X1.2.2 Restricted Source**—The flow generated by the source because of a particular failure is not sufficient to sustain the required pressure at the pressure relief valve inlet.

**X1.2.3 Restricted Discharge**—The outlet piping restriction results in a high backpressure buildup in the pressure relief valve outlet section to affect valve operation.

**X1.3 Restricted Inlet Piping**—The pressure relief valve is intended to control or limit the source pressure; however, the only pressure that it actually senses, and therefore, reacts to at any given instant, is the pressure immediately under the disk. Actually, it responds to the pressure differential between the valve inlet and valve outlet acting across the unbalanced disk area. The effect of any valve outlet pressure will be considered in X1.5. Therefore, for the pressure relief valve to function properly in response to a source condition, the pressure under the pressure relief valve disk must accurately reflect the pressure at the source at all times and under all flowing conditions. Before lift, the source pressure and the pressure under the disk are identical, since there is no flow of pressure medium. However, once the valve lifts and begins to relieve (discharge) fluid, there will be a pressure differential or pressure drop between the source pressure and the pressure under the disk, caused by the head loss through the inlet piping. If this pressure drop is small relative to the blowdown of the valve, the valve will remain open and continuously discharge fluid until the pressure at the source is reduced below the set pressure and normal and stable valve operation should result.

**X1.3.1 However, where the relief operation is limited by the inlet piping, the pressure drop during discharge may exceed the valve blowdown. If the pressure under the disk drops below the blowdown setting, the valve will immediately reseat as soon as it opens, even though the source pressure may still be above the set pressure or continuing to rise. Once the valve reseats, the valve stops relieving the fluid, and the pressure under the disk will immediately rise to match the source pressure. Assuming that the quantity of fluid discharged during this brief opening was not sufficient to bring the source pressure down below the set pressure, the valve will immediately reopen and a rapid chattering cycle will begin. The chattering will continue until the pressure at the source is reduced, in stages, to a value below the set pressure. Note that the rated capacity of the pressure relief valve, and not the available source supply, is critical since the pressure relief valve actually establishes the instantaneous or transient flow rate. Therefore, if the installation of a pressure relief valve results in a pressure drop in the inlet piping at the rated flow of the valve which approaches or exceeds the blowdown value of the valve, and the valve responds to an overpressure condition of any duration, chattering may occur. A chattering operation of a pressure relief valve will have the following detrimental effects:

**X1.3.1.1 Damage to the valve (particularly the seating surfaces) and the attached piping.**

**X1.3.1.2 Lowered Capacity**—The actual effective relieving capacity of a chattering pressure relief valve will be far below its rated capacity, which is based on a continuous open valve.

**X1.3.2 To prevent instability, the following criteria for pressure relief valve inlet piping installation should be followed:** The inlet piping connecting a pressure vessel, tank, pipe main, and other equipment being protected to the pressure relief valve inlet should have a streamlined entrance and should be as large in diameter, short in length, and direct as possible. Any changes in direction (elbows, bends, and so forth) should be avoided. The inlet piping should be arranged and sized so that the total pressure drop in the inlet piping does not exceed 25% of the blowdown of the pressure relief valve with a flow rate equal to the rated capacity of the pressure relief valve. For example, if a pressure relief valve is set at 100 psig and has a 10% blowdown and a capacity rating of 50 gpm at 10% accumulation, then the inlet piping should be arranged and sized so that it will pass a flow of 50 gpm with a pressure drop not exceeding 2.5 psi.

**X1.3.3 From the above, it can be seen that a pressure relief valve with very precise or narrow blowdown characteristics generally requires an installation with a very short and direct connection to the source. On the other hand, in existing installations in which the inlet connection is restrictive, a wide blowdown setting (where practical, based on other considerations) can improve stability. Another solution, in cases in which existing restrictive inlet piping cannot be replaced, would be the installation of a pilot-operated valve sensing directly to the source pressure. Since such a sensing line is always a very low-flow system, the valve will normally respond to the actual system pressure. As such, the pressure under the valve disk should have little effect on operating stability.

**X1.3.4 Another possible solution to a chattering problem in an existing installation is the substitution of a smaller size pressure relief valve, where permissible, based on other considerations. From a pressure drop standpoint, decreasing the capacity of the pressure relief valve has the same relative effect as increasing the size of the inlet piping. Where such a substitution results in a stable operating pressure relief valve, it can actually increase rather than decrease the effective protective capacity of a pressure relief valve installation.**

**X1.4 Restricted Source**—Chatter or unstable operation can occur when the rate of excess flow generated by the source is insufficient to sustain the valve in the open position during an overpressure condition. The mechanics and effects of this condition are the same as those resulting from restricted inlet piping, the only difference being the basic cause. This condition of insufficiency can be the result of oversizing the pressure relief valve in error or by deliberately oversizing the pressure relief valve in an effort to be on the “safe side.” This condition can also result from applications in which the pressure relief valve size is based on some maximum excess flow condition (for example, wide open failure of an upstream regulating valve) and the overpressure condition in most cases is caused by a lesser failure (for example, damage to the regulating valve
seat) which results in far less excess flow requiring discharge. When the pressure relief valve is merely oversized, it should be replaced with a valve of the correct capacity. As noted earlier, if such a substitution results in the elimination of a chattering condition, the result could be an increase in the effective relief protection capacity. In cases in which a variety of failures can require widely differing relief capacities, consideration should be given to installing two or more smaller size pressure relief valves with staggered settings.

X1.5 Restricted Discharge—The backpressure at the outlet section of a pressure relief valve can have a detrimental effect on valve operation. Under backpressure conditions, the pressure relief valve capacity is reduced because the valve lift is reduced by the increased pressure over the valve disk. Ideally, a pressure relief valve should only respond to the inlet (or source) pressure. However in valves that do not have a special balanced construction, any increase in the backpressure (which will have the effect of decreasing the pressure differential available to hold the disk in the open position) can have a similar effect on valve operation as a drop in the valve inlet pressure. Also, superimposed backpressure can shift the effective set pressure of a pressure relief valve. The following criteria for pressure relief valve discharge piping installation should be followed: The discharge piping should be arranged and sized so that the built-up backpressure does not cause unsatisfactory pressure relief valve operation, either from a stability or capacity standpoint. In cases in which a built-up backpressure in excess of 10% of the set pressure, or where a superimposed backpressure can exist in the discharge line, a pressure relief valve of balanced design should be used.

X1.6 Pressure Relief Valve Setting—To ensure good valve operation, the spread between the maximum system operating pressure and the pressure relief valve set pressure should always be as wide as possible, consistent with economical and safe system design. Pressure relief valves are generally set to open at 10% above the operating pressure. This margin will improve seat tightness (by permitting a greater normal seating load), decrease the number of times the valve is required to operate, and decrease valve maintenance. It will permit using a wider blowdown band, which can result in a more stable valve operation. X1.6.1 The two critical performance points in any pressure relief valve installation are the accumulation pressure and the blowdown pressure. The accumulation pressure (the maximum overpressure which the pressure relief valve will permit the source to reach) establishes the required design rating of the equipment being protected. Therefore, the accumulation pressure must be compatible with economical and practical system and component design or with the ratings of systems and components already designed or installed. The blowdown pressure (the pressure, below the set pressure, to which the source must drop before the pressure relief valve will reseat) must always be above the maximum system operating pressure.

X1.6.2 From an economical point of view, the blowdown should be as short as possible. However, from the point of stable valve operation, a high blowdown is desirable. A compromise may therefore have to be accepted.

X1.6.3 If the blowdown pressure and the maximum system operating pressure are too close together, or if they can cross over, there is the possibility that a condition can be set up where, after responding to an overpressure, the system must be secured to stop the discharging of the pressure medium before the pressure relief valve will reseat. The higher the valve set pressure can be set above the maximum system operating pressure, the wider (or less precise) the spread between the accumulation and blowdown limits which can be permitted, and therefore, the less critical pressure relief valve operation becomes.

X1.6.4 Therefore, the selection and installation of pressure relief valve protection always involves compromises between system design considerations and pressure relief valve design considerations. As stated previously, the blowdown and accumulation are the only critical pressure relief valve performance points from a system standpoint. The actual set pressure is of little importance aside from providing a reference for setting and checking the valve. If the blowdown pressure and accumulation pressure meet system requirements, the set pressure can fall anywhere in between.

X1.7 Installation Forces—Forces transmitted to a pressure relief valve by thermal stresses, forced alignment of piping, and inadequate supports tend to distort the valve body. These forces should be avoided since the operation of pressure relief valves is particularly sensitive to such influences. The piping must also be designed and adequately supported to withstand the reactive forces associated with pressure relief valve discharge.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Specification for Rotary Positive Displacement Pumps, Commercial Ships Use

This standard is issued under the fixed designation F 1510; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This specification defines the requirements applicable to design and construction of rotary positive displacement pumps for shipboard use. The classes of service are shown in Section 4.
1.2 This specification will not include pumps for hydraulic service or cargo unloading applications.

2. Referenced Documents
2.1 ASTM Standards:
- A 27/A 27M Specification for Steel Castings, Carbon, for General Application
- A 36/A 36M Specification for Carbon Structural Steel
- A 48 Specification for Gray Iron Castings
- A 53 Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated Welded and Seamless
- A 159 Specification for Automotive Gray Iron Castings
- A 193/A 193M Specification for Alloy-Steel and Stainless Steel Bolting Materials for High-Temperature Service
- A 194/A 194M Specification for Carbon and Alloy Steel Nuts for Bolts for High-Pressure and High-Temperature Service, or Both
- A 322 Specification for Steel Bars, Alloy, Standard Grades
- A 354 Specification for Quenched and Tempered Alloy Steel Bolts, Studs, and Other Externally Threaded Fasteners
- A 434 Specification for Steel Bars, Alloy, Hot-Wrought or Cold-Finished, Quenched and Tempered
- A 449 Specification for Quenched and Tempered Steel Bolts and Studs
- A 515/A 515M Specification for Pressure Vessel Plates, Carbon Steel, for Intermediate— and Higher-Temperature Service
- A 536 Specification for Ductile Iron Castings
- A 563 Specification for Carbon and Alloy Steel Nuts
- A 564/A 564M Specification for Hot-Rolled and Cold-Finished Age-Hardening Stainless Steel Bars and Shapes
- A 574 Specification for Alloy Steel Socket-Head Cap Screws
- A 582/A 582M Specification for Free-Machining Stainless Steel Bars
- B 150 Specification for Aluminum Bronze Rod, Bar, and Shapes
- B 584 Specification for Copper Alloy Sand Castings for General Applications
- D 1418 Practice for Rubber and Rubber Lattices—Nomenclature
- D 2000 Classification System for Rubber Products in Automotive Applications
- D 3951 Practice for Commercial Packaging
- F 104 Classification System for Nonmetallic Gasket Materials
- F 593 Specification for Stainless Steel Bolts, Hex Cap Screws, and Studs
- F 912 Specification for Alloy Steel Socket Set Screws
- F 1511 Specification for Mechanical Seals for Shipboard Pump Applications

2.2 ANSI Standard:
- B 16.5 Pipe Flanges and Flanged Fittings

3.1.17 suction lift—a term used to define a pump’s capability to induce a partial vacuum at the pump inlet.

3.1.18 temperature, maximum allowable—the maximum continuous temperature for which the manufacturer has designed the equipment (or any part to which the term is referred) when handling the specified fluid at the specified pressure. This pressure should not be greater than \( \frac{2}{3} \) of the hydrostatic test pressure of the pressure containing parts.

3.1.19 net positive inlet pressure available (NPIPA)—the total inlet pressure available from the system at the pump inlet connection at the rated flow, minus the vapor pressure of the liquid at the pumping temperature.

3.1.10 net positive inlet pressure required (NPIPR)—the net pressure above the liquid vapor pressure at rated flow and pumping temperature and at the pump inlet connection required to avoid performance impairment due to cavitation.

3.1.11 pressure, cracking—sometimes called set pressure, start-to-discharge pressure, or popping pressure—the pressure at which the relief valve just starts to open. This pressure cannot be determined readily if the relief valve is internal to the pump and it bypasses the liquid within the pump.

3.1.12 pressure, differential—the difference between discharge pressure and inlet pressure.

3.1.13 pressure, discharge—the pressure at the outlet of the pump. Discharge pressure is sometimes called outlet pressure.

3.1.14 pressure, inlet—the total pressure at the inlet of the pump. Inlet pressure is sometimes called suction pressure.

3.1.15 pressure, maximum allowable working—the maximum continuous pressure for which the manufacturer has designed the equipment (or any part to which the term is referred) when handling the specified fluid at the specified temperature. This pressure should not be greater than \( \frac{2}{3} \) of the hydrostatic test pressure of the pressure containing parts.

3.1.16 rated condition—defined by discharge pressure, inlet pressure, capacity, and viscosity.

3.1.17 rotary pump—a positive displacement pump consisting of a casing containing gears, screws, lobes, cams, vanes, shoes, or similar elements actuated by relative rotation between the drive shaft and the casing. There are no inlet and outlet valves. These pumps are characterized by their close running clearances.

3.1.18 slip—the quantity of fluid that leaks through the internal clearances of a rotary pump per unit of time. Slip depends on the internal clearances, the differential pressure, the characteristics of the fluid handled and in some cases, the speed.

3.1.19 speed, maximum allowable (in revolutions per minute)—the highest speed at which the manufacturers’ design will permit continuous operation.

3.1.20 speed, minimum allowable (in revolutions per minute)—the lowest speed at which the manufacturers’ design will permit continuous operation.

3.1.21 speed, rated—the number of revolutions per minute of the driving rotor required to meet the rated conditions.

3.1.22 suction lift—a term used to define a pump’s capability to induce a partial vacuum at the pump inlet.

3.1.23 temperature, maximum allowable—the maximum continuous temperature for which the manufacturer has designed the equipment (or any part to which the term is referred) when handling the specified fluid at the specified pressure.

4. Classification

4.1 Pumps will be classified as follows:

4.1.1 Types:

4.1.1.1 Type II—Screws with timing gears.

4.1.1.2 Type III—Screws without timing gears.

4.1.1.3 Type IV—Impellers with timing gears.
4.1.4 Type V—External gear (spur, helical, herringbone, lobe).
4.1.5 Type VIII—Internal gear, internal rotary lobe.
4.1.6 Type X—Vane (sliding).
4.1.7 Type XI—Sliding shoe.

4.2 Classes:
4.2.1 Class A—Aqueous film forming foam, AFFF.
4.2.2 Class B—Bromine.
4.2.3 Class CD—Clean distillate fuel, viscosity 32 to 100 SSU (2 to 21 centistokes) (for example, jet fuel, JP-5, fuel).
4.2.4 Class CH—Clean heavy fuel, viscosity 100 to 1500 SSU (21 to 325 centistokes) (propulsion fuel).
4.2.5 Class DD—Dirty distillate fuel, viscosity 32 to 100 SSU (2 to 21 centistokes) (for example, transfer, stripping, purifier feed, leak-off).
4.2.6 Class DH—Dirty heavy oil, viscosity 32 to 4000 SSU (2 to 863 centistokes) (for example, waste oil, transfer, stripping, purifier feed, leak-off).
4.2.7 Class G—Gasoline, aviation gasoline, gasohol.
4.2.8 Class LM—Lube oil, viscosity 130 to 4000 SSU (27 to 863 centistokes) (for example, propulsion, SSTG, control, L.O. service).
4.2.9 Class LA—Auxiliary L.O. 130 to 4000 SSU (27 to 863 centistokes) service and L.O. transfer.
4.2.10 Class M—Miscellaneous.
4.2.11 Class W—Heavily contaminated seawater, viscosity 32 to 4000 SSU (2 to 863 centistokes) (bilge stripping, oily waste transfer).

5. Ordering Data
5.1 The ordering activity shall provide manufacturers with all of the following information:

5.1.1 Title, number, and date of specification,
5.1.2 Type and classification, see Section 4,
5.1.3 Capacity in gallons per minute or litres per minute at rated discharge pressure,
5.1.4 Discharge pressure in pound-force per square inch gage (psig) or kilopascal (kPa) gage,
5.1.5 Airborne noise levels (if different than 7.5),
5.1.6 Viscosity (only if different than Section 4),
5.1.7 Mounting configuration (vertical, horizontal),
5.1.8 Driver type (motor, turbine, engine, attached),
5.1.9 Driver characteristics or specifications, or both,
5.1.10 Relief valve cracking pressure and full-flow bypass pressure,
5.1.11 Packaging and boxing requirements (immediate use, domestic; storage, domestic; overseas),
5.1.12 Quantity of pumps,
5.1.13 Quantity of drawings,
5.1.14 Quantity of technical manuals,
5.1.15 Quantity of test reports,
5.1.16 Performance test, if required,
5.1.17 Certified data required, and
5.1.18 Instruction plates and locations, if required.

6. Materials
6.1 Pump component parts shall be constructed of the materials shown in Table 1.

6.2 Materials other than shown in Table 1 are considered exceptions and are subject to approval by the purchaser before usage.

7. General Requirements
7.1 Pumps shall be designed for a 20-year service life.
7.2 Pumps shall be capable of sustained operation during inclinations up to 45° in any direction.
7.3 The pumps shall be capable of withstanding environmental vibration induced by shipboard machinery and equipment in the frequency range from 4 to 25 Hz.
7.4 The internally excited vibration levels of the pump shall not exceed 0.003-in. (0.00762-mm) displacement peak to peak during rated operation when readings are measured on the pump case near the coupling perpendicular to the pump shaft.
7.5 At normal operating conditions, the airborne noise level of the pump shall not exceed 85 dBA.
7.6 The pump driver (electric motor, air motor, turbine, hydraulic motor, diesel engine, attached) shall be as specified in the ordering data. The driver shall be sized for maximum flow at the relief valve full-flow bypass pressure, at maximum viscosity. If a two-speed motor is specified for high-viscosity Class LM applications, the motor size shall be based on power required at low speed, which is used during cold startup.
7.7 If a reduction gear is required between the driver and the pump, it shall be provided by the pump manufacturer. Reduction gears shall meet the requirements of AGMA 390.03. Gears shall be AGMA Class 7 or better, pinions shall be AGMA Class 8 or better, and bearings shall be designed for a L10 life of 15,000 h.
7.8 Horizontal pumps may be mounted on a common horizontal bedplate with the driving unit or mounted directly to the driver. Vertical pumps may be mounted with a bracket to the driving unit or mounted directly to the driver.
7.9 All pump units shall incorporate guards over couplings, belts, and other external rotating parts.
7.10 The mounting arrangement shall be sufficiently rigid to assure alignment is maintained between the pump and the driver in accordance with the conditions in 7.2, 7.3, and 8.1.
7.11 Seating surfaces of mounting bedplates, bracket mounting plates, or other mounting arrangements shall be machined.
7.12 Mounting bedplates, brackets, and plates shall be provided with holes of sufficient size and quantity to assure adequate attachment to shipboard foundation or mounting structure.
7.13 Vertical units with face mounted motors shall be arranged so there are four (4) possible orientations of motor driver to pump. Other drivers are to be oriented in accordance with the ordering information.
7.14 Vertical units that are motor driven shall be assembled with the conduit box mounted over the pump inlet flange, unless otherwise specified.
7.15 Couplings between the pump and the driver shall be keyed to both shafts.
7.16 Alignment between the pump and the driver shall not exceed 0.005-in. (0.13-mm) offset and 0.0005-in./in. (0.01-mm/mm) angularity.
7.17 An external (separate) relief valve shall not be provided with the pump unless otherwise specified. The purchaser shall provide the cracking pressure and the fullflow bypass pressure of the system relief valve to the pump manufacturer.

7.18 Direction of rotation shall be indicated by an arrow cast into the pump or by a label plate attached to the pump.

7.19 Inlet and outlet connections shall be indicated by a label plate attached to each flange.

8. Pump Design

8.1 Pump inlet and outlet connections shall be flanged. Steel case pump flanges shall be in accordance with ANSI B16.5 raised face. Cast gray iron and nonferrous material cases shall be in accordance with ANSI B16.5 flat face, unless otherwise stated in the ordering data. Flanged connections shall meet the requirements in API Standard 676, Paragraph 2.4.7. Spool...
piece adapters (threaded and seal welded, or O-ring sealed to the pump case on one end and flanged on the other end) may be furnished to meet the flanged inlet and outlet requirement.

8.2 Pump cases shall be equipped with vent, drain, inlet, and outlet gage connections. The connection shall be straight thread with an O-ring seal. Tapered pipe thread connections are prohibited. Small pumps do not require vent, drain, and gage connections.

8.3 Materials for the pump shall be compatible with the fluid being pumped, and the operating parameters to be encountered including maximum pressure and temperature extremes stated in the ordering data.

8.4 Pumps shall be equipped with radial and thrust bearings as necessary to counteract any unbalanced forces in the pump and to ensure that the pump will operate satisfactorily in accordance with 7.2.

8.5 Bearings shall be securely fitted (by snap rings, shoulders, or other means) to prevent axial movement. Bearing housings shall be integral to the pump case or secured to the pump case in such a manner as to ensure alignment. Usage of bolts alone is not considered sufficient to ensure alignment.

8.6 Bearings may be sealed and self-lubricated or externally lubricated or may be lubricated by the liquid being pumped.

8.7 Rolling contact bearings shall be selected in accordance with AFBMA standards and shall have a minimum L10 life of 15 000 h as calculated in accordance with AFBMA Standard 9 or 11 as appropriate.

8.8 Pumps shall be equipped with mechanical shaft seals, in accordance with Specification F 1511. The installation shall ensure that adequate circulation of liquid at the seal faces occurs to minimize deposit of foreign matter and provide adequate lubrication of the seal faces.

8.9 Mechanical seals shall be positioned or located on the shaft axially, by a positive means such as a stub, step, or shoulder positively located on the pump shaft. Set screws shall not be used to position seals or seal sleeves axially. An antirotation pin may be provided to prevent the mechanical seal-mating ring from rotating.

8.10 When required by the ordering data, the pump shall be equipped with a backup packing box. The design shall allow for installation of two or more rings of packing for use in the event of a mechanical seal failure. The packing rings shall be able to be inserted without having to remove the mechanical seal.

8.11 Pump head or end covers, or both, shall be located to the pump case by a means such as rabbot, dowels, or pilot to ensure proper alignment.

8.12 Rotors and timing gears shall be machined and positively secured in position to maintain required clearances and prevent undue wear.

8.13 Fasteners shall be selected from Table 1 taking into consideration temperature of operation, mechanical properties, and corrosion resistance.

9. Performance Requirements

9.1 Pumps shall deliver the rated capacity at 10-psia (69-kPa absolute) inlet pressure while operating at the parameters specified in the ordering data.

9.2 The maximum capacity of the pump shall not exceed the amount determined by the following formula:

\[
Q_{\text{max}} = Q \left[ 1 + \frac{1}{Q_{\text{F}}^2} \right]^{0.4}
\]

where:

- \(Q\) = rated capacity and
- \(Q_{\text{max}}\) = maximum allowable capacity, at minimum viscosity. \(Q_{\text{max}}\) shall be rounded to the nearest whole number.

9.3 Capacity of all classes (except DH) pumps shall not be less than the value stated in 5.1.3 at the rated conditions, with minimum viscosity.

9.4 Class DH pumps shall meet the capacity requirements at 4000 SSU (863 centistokes) and shall not be damaged by continuous operation at 32 SSU (2 centistokes).

9.5 Class LM & LA pumps shall meet the capacity requirements at 130 SSU (27 centistokes) and driver horsepower shall be determined based on 4000 SSU (863 centistokes).

10. Painting and Coatings

10.1 Painting—External unmachined and nonmating machined surfaces shall be thoroughly cleaned and painted.

10.2 Painting external surfaces of nonferrous parts and components is not required but is permissible to avoid excessive masking. Identification and information plates shall not be painted or oversprayed.

11. Equipment Identification and Instruction Plates

11.1 Identification plates shall be made of brass or stainless steel and furnished on each pump unit.

11.2 Instruction plates shall be made of brass, stainless steel, or plastic when furnished on each pump unit.

11.3 Plates shall be secured to equipment with corrosion-resistant metallic fasteners.

11.4 Pump unit identification plates shall contain data as follows:

11.4.1 Manufacturer's name.

11.4.2 Manufacturer's model or type and size.

11.4.3 Service application.

11.4.4 Manufacturer's serial number.

11.4.5 Salient design characteristics if applicable.

11.4.5.1 Capacity.

11.4.5.2 Discharge pressure.

11.4.5.3 Pump rated speed (RPM).

11.5 Accessory units such as the driver, controller, pump, and gearbox, shall have an identification plate in accordance with the applicable equipment specification. If not specified, the manufacturer shall use its commercial nameplate.

12. Testing Requirements

12.1 General—All equipment shall be tested in accordance with 12.2 and 12.3. The first unit of a new design or size shall be tested in accordance with 12.4 and 12.5.

12.1.1 Equipment for specified tests shall be provided by the manufacturer.
12.1.2 Acceptance of tests does not constitute a waiver of requirements to meet performance under specified operating conditions, nor does inspection relieve the manufacturer of his responsibilities.

12.1.3 The manufacturer shall maintain a complete log of the tests performed and shall prepare the required number of copies of the test report, certified as to correctness.

12.2 Hydrostatic Test—Pressure-containing parts shall be tested hydrostatically with liquid at a minimum of 1 1/2 times the maximum allowable working pressure but at not less than 50-lb/in.² (345-kPa) gage. The hydrostatic test shall be considered satisfactory when no leaks are observed for a minimum of 5 min. Seepage past internal closures required for segmented casing testing and operating of the hydrostatic test pump to maintain pressure will be accepted.

12.3 Mechanical Running Test—The pump manufacturer shall conduct a test on all pumps to ensure that rated capacity is achieved at the rated condition. Such tests may be performed with other than the specified liquid if the viscosity is equal to the minimum viscosity for the class of pump being tested. A viscosity up to 50 SSU greater than the minimum viscosity may be used. Differential pressure may be measured in lieu of inlet pressure and discharge pressure.

12.4 Performance Test—The pump manufacturer shall operate a pump at the manufacturing facility or approved test facility to obtain complete test data when required by the ordering document (5.1.15). The pump shall be tested at rated speed, discharge pressure, viscosity, and 10-psia (69-kPa absolute) inlet pressure. The pump shall meet rated capacity at this condition and shall meet the airborne noise levels in 7.5. This test is normally required for new types, new designs, or new applications of pumps.

12.5 Certified Data—Certified performance data or curves shall be supplied when required, see 5.1.16.

13. Technical Documents

13.1 An outline or top drawing of the unit (pump and driver) shall be furnished. Length, width, height, mounting details, and connections shall be dimensioned.

13.2 Complete performance curves shall be furnished. The curves may be on graphs which can be printed on notebook size paper.

13.3 Pump drawings shall include a sectional assembly drawing. The sectional assembly drawing shall contain a complete list of materials or reference to a list of materials drawing, which shall be provided.

13.4 Brackets, bedplates, guards, couplings, identification plates, rotation arrows, and so forth shall be shown on the outline drawing.

13.5 Any subassembly made up of parts that require special alignment or assembly methods that cannot be disassembled, repaired, and reassembled onboard ship without the use of special tools and jigs shall be indicated as a subassembly in the list of material.

13.6 Drawings for driver and associated equipment shall be in accordance with their respective specifications.

13.7 The weight and center of gravity (calculated or actual) of the unit shall be indicated on the outline drawing.

13.8 Instruction books or technical manuals shall be prepared for each different type or size of pump installed. A single manual shall contain not more than one type or size of pump. However, when several pumps are installed in a ship that are identical except for type of driver, they may be included in a single manual.

13.9 Piece (item or find) numbers of parts referred to in technical manuals shall match the piece numbers shown on pump drawings.

13.10 Technical manuals shall contain reproductions of pump drawings.

13.11 Quantities of technical manuals shall be in accordance with the order.

14. Packaging and Preservation

14.1 Pumps, pump units, and accessories shall be packaged and preserved in accordance with Practice D 3951, and the following:

14.2 Preservation—Items susceptible to deterioration or damage from environmental elements shall be preserved. Noncoated ferrous surfaces shall be preserved.

14.3 Cushioning and Bracing—Items susceptible to damage during shipment and handling shall be cushioned or shall be securely braced or blocked, or both, within the shipping container, to avoid damage.

14.4 Container Marking—Containers, boxes, or packages shall be clearly marked with the ship to address, contract or purchase order number, shipping point address, and item nomenclature.

15. Keywords

15.1 positive displacement pump; pump; rotary pump; shipboard pump
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established by the U.S. Navy, Commander Naval Sea Systems Command (NAVSEA) shall apply when specified in the contract or purchase order. When there is a conflict between the specifications and this section, requirements of this section shall take precedence.

S1.1 Materials other than shown in Table 1 are considered exceptions and are subject to approval by NAVSEA.

S1.2 The pumps shall be capable of withstanding environmental vibration induced by shipboard machinery and equipment in the frequency range of 4 to 25 Hz and be in accordance with MIL-STD-167, Type 1. Maximum single frequency displacement (double amplitude) in the 4- to 15-Hz range is 0.060 in. (1.524 mm) and in the 16- to 25-Hz range is 0.040 in. (1.016 mm).

S1.3 The internally excited vibration levels of the pump shall be in accordance with MIL-STD-167, Type II and shall not exceed 0.003-in. (0.076-mm) displacement peak to peak during rated operation when readings are measured on the pump case near the coupling perpendicular to the pump shaft.

S1.4 At the conditions in Section 9, the airborne noise level of the pump unit shall meet the requirements in Table S1.1 (see MIL-STD-740-1).

S1.5 At the conditions in Section 9, the structureborne noise level of the pump unit shall meet the requirements in Table S1.2 (see MIL-STD-740-2).

S1.6 Pumps shall meet the requirements of MIL-S-901 HI (High Impact) Shock, Grade A.

S1.7 Mechanical shaft seals shall be in accordance with Specification F 1511, including Supplement S1. An anti-rotation pin shall be provided for seal O-ring mating rings in shaft sizes 1” and larger, when the pump will be handling viscous fluids over 130 ssu (27 centistrokes). Pin diameter and length shall be compatible with the slot in the ring.

S1.8 Qualification Tests—The first pump of each size, type, or design shall meet the following qualification tests. All tests shall be performed with the motor size required at rated condition as indicated in Section 9.

S1.9 Performance Test—The pump shall be tested at the conditions in Section 9 to demonstrate that the pump is capable of delivering the required capacity. Record all test data including electrical power input for comparison to performance retest results (see S1.15).

S1.10 Vibration Type II Test—The pump shall be tested to demonstrate the ability to meet the requirements of S1.3. Record all test data, including electrical power input, for comparison to performance retest results (see S1.15).

S1.11 Noise Tests—The pump shall be tested to demonstrate the ability to meet the requirements of S1.4 and S1.5. Record all test data, including electrical power input, for comparison to performance retest results (see S1.15).

S1.12 Vibration Type I Test—The pump shall be tested to demonstrate the ability to meet the requirements of S1.2.

S1.13 Shock Test—The pump shall be tested to demonstrate the ability to meet the requirements of S1.6.

S1.14 Endurance Test—The endurance test shall consist of a running test of not less than 500 h of actual running time at rated condition. The 500 h shall be broken by at least three rest periods of 8 h or more each. A minimum of ten start-stop cycles shall be performed during the course of the test.

S1.15 Performance Retest—Upon completion of the tests in S1.9 through S1.14, repeat the performance test (S1.9), the Vibration Type II test (S1.10), and the noise test (S1.11). Record all test data.

S1.16 Test Reports—A test report shall be submitted for each test conducted. Quantity and format as defined in the ordering data.

Standard Specification for
Mechanical Seals for Shipboard Pump Applications

This standard is issued under the fixed designation F 1511; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers mechanical end-face seals for centrifugal and positive displacement pumps for shipboard use.

1.2 The following types of seals are not included in this specification: lip seals, oil seals, circumferential seals, or labyrinth seals.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI units given in parentheses are for information only. A companion hard metric standard is in the process of preparation.

1.4 Special requirements for U.S. Navy Shipboard Pump Applications are included in Supplement S1.

2. Referenced Documents

2.1 ASTM Standards:

A 108 Specification for Steel Bars, Carbon, Cold-Finished, Standard Quality
A 182/A182M Specification for Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service
A 240/A 240M Specification for Chromium and Chromium-Nickel Stainless Steel Plate, Sheet, and Strip for Pressure Vessels and for General Applications
A 276 Specification for Stainless Steel Bars and Shapes
A 313/A 313M Specification for Stainless Steel Spring Wire
A 351/A351M Specification for Castings, Austenitic, Austenitic-Ferritic (Duplex), for Pressure-Containing Parts
A 436 Specification for Austenitic Gray Iron Castings
A 494/A494M Specification for Castings, Nickel and Nickel Alloy
A 564/A564M Specification for Hot-Rolled and Cold-Finished Age-Hardenig Stainless Steel Bars and Shapes
A 579 Specification for Superstrength Alloy Steel Forgings
A 693 Specification for Precipitation-Hardening Stainless and Heat-Resisting Steel Plate, Sheet, and Strip
A 705/A705M Specification for Age-Hardenig Stainless and Steel Forgings
A 744/A744M Specification for Castings, Iron-Chromium-Nickel, Corrosion Resistant, for Severe Service
B 62 Specification for Composition Bronze or Ounce Metal Castings
B 127 Specification for Nickel-Copper Alloy (UNS N04400) Plate, Sheet, and Strip
B 164 Specification for Nickel-Copper Alloy Rod, Bar, and Wire
B 166 Specification for Nickel-Chromium-Iron Alloys (UNS N06600, N06601, N06603, N06690, N06693, N06025, and N06045) and Nickel-Chromium-Cobalt-Molybdenum Alloy (UNS N06617) Rod, Bar, and Wire
B 168 Specification for Nickel-Chromium-Iron Alloys (UNS N06600, N06601, N06603, N06690, N06693, N06025, and N06045) and Nickel-Chromium-Cobalt-Molybdenum Alloy (UNS N06617) Plate, Sheet, and Strip
B 271 Specification for Copper-Base Alloy Centrifugal Castings
B 333 Specification for Nickel-Molybdenum Alloy Plate, Sheet, and Strip
B 335 Specification for Nickel-Molybdenum Alloy Rod
B 338 Specification for Seamless and Welded Titanium and Titanium Alloy Tubes for Condensers and Heat Exchangers
B 348 Specification for Titanium and Titanium Alloy Bars and Billets
B 367 Specification for Titanium and Titanium Alloy Castings
B 443 Specification for Nickel-Chromium-Molybdenum-Columbium Alloy (UNS N06625) and Nickel-Chromium-Molybdenum-Silicon Alloy (UNS N06219) Plate, Sheet, and Strip
B 446 Specification for Nickel-Chromium-Molybdenum-Columbium Alloy (UNS N06625), Nickel-Chromium-Molybdenum-Silicon Alloy (UNS N06219) and Nickel-Chromium-Molybdenum-Tungsten Alloy (UNS N06650) Rod and Bar
B 472 Specification for Nickel Alloy UNS N06030, UNS N06022, UNS N06200, UNS N08020, UNS N08026, UNS N08800, UNS N08801, UNS N08802, and UNS N08803

This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.11 on Machinery and Piping Systems.

For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For Annual Book of ASTM Standards volume information, refer to the standard’s Document Summary page on the ASTM website.
N08024, UNS N08926, UNS N08367, UNS N10276, UNS N10665, UNS N10675 and UNS R20033 Nickel Alloy Billets and Bars for Reforging
B 473 Specification for UNS N08020, UNS N08024, and UNS N08026 Nickel Alloy Bar and Wire
B 505 Specification for Copper-Base Alloy Continuous Castings
B 584 Specification for Copper Alloy Sand Castings for General Applications
B 637 Specification for Precipitation-Hardening Nickel Alloy Bars, Forgings, and Forging Stock for High-Temperature Service
B 670 Specification for Precipitation-Hardening Nickel Alloy (UNS N07718) Plate, Sheet, and Strip for High-Temperature Service
D 1141 Specification for Preparation of Substitute Ocean Water
D 1418 Practice for Rubber and Rubber Latices Nomenclature
D 3294 Specification for Polytetrafluoroethylene (PTFE) Resin Molded Basic Shapes
D 3951 Practice for Commercial Packaging
2.2 ASQ Standards:
2.3 ANSI Standards:

2.4 Military Standards:
MIL-S-901 Shock Tests, H.I. (High Impact); Shipboard Machinery, Equipment & Systems, Requirements for
MIL-P-16789 Packaging of Pumps, Including Prime Movers and Associated Repair Parts
MIL-R-83248 Rubber Fluorocarbon Elastomer, High Temperature, Fluid, and Compression Set Resistant
MIL-STD-167-1 Environmental Vibration Testing
2.5 ISO Standard:
2.6 Other Document:
Metals and Alloys — Unified Numbering System-DS-56f
3. Terminology
3.1 Refer to Annex A1 for terminology relating to mechanical seals.
4. Classification of Seal Arrangements
4.1 For this specification, mechanical seals shall be classified by type, grade, and class. The categories are divided by application arrangement in the equipment in which it is installed:
4.1.1 Type A—Inside Single Mounted Seals
4.1.2 Type B—Outside Single Mounted Seals
4.1.3 Type C—Double Seals
4.1.4 Type D—Tandem Seals
4.1.5 Type E—Gas Seals
4.1.6 Type F—Special Arrangements/Applications Vacuum or Gas Seal
4.1.7 Grade 1—Basic End Face Seal
4.1.8 Grade 2—Cartridge Seal
4.1.9 Grade 3—Split Seal
4.1.10 Class 0—Nonsplit Seal Assembly
4.1.11 Class 1—Partial Split Seal Assembly, Solid Gland
4.1.12 Class 2—Partial Split Seal Assembly, Split Gland
4.1.13 Class 3—Fully Split Seal Assembly, Solid Gland
4.1.14 Class 4—Fully Split Seal Assembly, Split Gland
4.2 Figs. 1-6 give general orientation information for various types of seals. The specific design of seal shown is not limited to that particular application.
5. Ordering Information
5.1 The purchaser (buyer) shall provide the manufacturer with all of the pertinent application data shown in Figs. 7-9. If special operating conditions exist that are not shown in the checklist, they shall also be described.
6. Material
6.1 Mechanical seals shall be constructed of materials selected from Tables 1-3 after reviewing temperature, pressure/velocity (PV), and corrosion resistance requirements for all parts for each application.
6.2 Metal Components:
6.2.1 Mechanical seal metal parts in contact with the pumped liquid shall be compatible with their environment.
6.2.2 Table 1 identifies metal component compatibility.
6.2.3 Material specifications:
FIG. 1 Single Seal—Inside Bellows Secondary Seal, Classification Type A Grade 1

FIG. 2 Single Seal—Inside O-Ring Secondary Seal, Classification Type A Grade 1
FIG. 3 Single Seal—Outside Mounted Classification Type B Grade 1

FIG. 4 Double Seals—Back to Back Classification Type C Grade 1
FIG. 5 Double Seals—Face to Face Classification Type C Grade 1

FIG. 6 Tandem Seals Classification Type D Grade 1

A Monel® or equivalent has been found satisfactory for this purpose.
B Hastelloy B or equivalent has been found satisfactory for this purpose.

6.3 Face Materials—Mechanical seal-wearing faces shall be selected to provide the desired performance and corrosion resistance for the specified design life of the seal.

6.3.1 Performance ranges for face combinations are listed in Table 2.

6.3.2 Face materials shall be of solid construction only; no overlays, deposited coatings, or sprayed on coatings are permitted.

6.3.3 Carbon is preferred for one of the faces unless the service is abrasive, dirty, or chemically active.

6.3.4 For special service requirements, hard on hard seal face combinations may be required. Face material combinations, such as silicon carbide versus silicon carbide, silicon carbide versus tungsten carbide, and tungsten carbide versus tungsten carbide, may be used as similar or dissimilar contacting face materials when recommended by the supplier and approved by the user.

6.4 Face Material Specifications:

6.4.1 Material—Suitable for service as recommended by the manufacturer. A carbon seal grade is a material having carbonaceous filler system comprised of pitch and resins, compacted and baked to a final temperature. These grades are subsequently impregnated with resin until they become impervious. All available carbons may not be suitable for a particular application. Carbons considered for use in a particular application shall be checked for suitability in accordance with the requirements of this specification.

6.4.2 Tungsten Carbide—6 to 10 % nickel or cobalt-bound solid tungsten carbide.

6.4.3 Ceramic—99.5 % minimum alumina ceramic suitable for the service as recommended by the manufacturer.

6.4.4 Silicon Carbide—(a) Reaction-Bonded—Solid fine-grained reaction-bonded silicon carbide 8 to 12 % free silicon, essentially free of carbon, impervious structure requiring no impregnant. (b) Reaction-Bonded With Graphite—A composite material of fine-grain reaction-bonded silicon carbide; 5 to 10 % free silicon and 10 to 30 % graphite; impervious structure requiring no impregnant. (c) Direct Sintered—Solid homogeneous silicon carbide essentially free of silicon and carbon, impervious structure requiring no impregnant. (d) Direct Sintered Silicon Carbide—Contains 10 % free graphite. (e) Silicocarbonized Carbon Graphite—Approximately 0.025-in. (0.64-mm) thick conversion of silicon carbide on carbon substructure and impregnated with thermosetting resin.

6.5 Elastomeric Materials:

6.5.1 Special care should be given to the selection and installation of elastomeric components, such as bellows and O-rings. One of the most important considerations for elastomers is fluid compatibility. Table 3 references most shipboard applications. Consult the seal manufacturer for fluids not listed.

6.5.2 Material Classification/Specification:

6.5.2.1 Nitrile—Practice D 1418, Class Designation NBR.
6.5.2.2 Chloroprene—Practice D 1418, Class Designation CR.
6.5.2.3 Fluorocarbon—Practice D 1418, Class Designation FKM.
FIG. 8 Stuffing Box Arrangement
6.5.2.4 Ethylene Propylene (EP)—Practice D 1418, Class Designation EPM/EPDM.

6.5.2.5 Perfluoroelastomer—Practice D 1418, Class Designation FFKM.

6.5.2.6 Polytetrafluorethylene (PTFE)—Specification D 3294.

6.5.2.7 Corrugated graphite ribbon packing.

6.5.3 Ethylene propylene (EP) rubber shall not be lubricated with any petroleum base substances. Check Section 11 and Appendix X1 or manufacturer’s recommendations before using any lubricant.

7. Performance Requirements

7.1 Seal life shall be defined in terms of the time period in which the mechanical seal functions properly under its specified service.

7.1.1 The minimum operational life of a mechanical seal shall be 16,000 statistical hours provided that the equipment is maintained and operated in accordance with the requirements of Section 8.

$^{\mathrm{a}}$ Values of PV apply to aqueous solutions at 120°F (49°C). For lubricating liquids, such as oil, 60 % higher can be used. Given limits are to be used as a general guide in material selection. Values used consider a pressure drop across the seal faces as 0.5.

$^{\mathrm{b}}$ Limited to chemical service requirements only.

$^{\mathrm{c}}$ PV limit of 185 000 (6.57) can be used with two different grades of tungsten carbide, that is, cobalt versus nickel binders.

7.1.2 During any portion of the service life, the dynamic leakage shall not exceed five drops per minute for Class 0 seals. After initial installation, hydrostatic leakage shall be zero for a 5-min period, when the equipment is subjected to system pressure.

7.1.3 All split mechanical seals, Classes 1 through 4, may experience higher leakage rates than Class 0, solid mechanical seals. A leakage rate of five drops per minute shall be acceptable after completion of the manufacturer’s recommended break-in period.

7.1.4 In special applications of extreme environmental parameters, such as high temperature with limited cooling, high pressure/velocity, extreme abrasion, unusual equipment vibration, shaft end-play, or run-out, the pump and seal manufacturers shall agree upon the best achievable minimum operating life requirements and leakage performance.

7.1.5 Double or special seal arrangements may be required in applications in which zero product leakage to the environment is required such as hazardous fluids, fuel oil, acids, chemicals, and sewage. Consult the seal manufacturer for recommendations.

8. Design Requirements

8.1 Installation Arrangements:

8.1.1 Type A mechanical seals shall be provided unless otherwise specified.

8.1.2 Tandem or double mechanical seals may be installed in special applications in which it is determined that a buffer fluid system is required for lubrication, containment, or safety.

8.2 Finish and tolerance requirements for primary seal ring and mating ring surface flatness of Class 0 mechanical seals shall be three light bands or better as measured under a monochromatic, helium light source.

8.3 Requirements for Installation of Classes 1 Through 4 Split Mechanical Seals:

8.3.1 Classes 1 through 4, split mechanical seals, may be furnished for shaft/sleeve diameters of 1½ in. (38.1 mm) and above.

8.3.2 For split mechanical seal installations, a minimum of 3 in. (76.2 mm) of axial space, measured from the stuffing box face to the first obstruction, shall be provided for Classes 2 and 4 seals. Additional space, at least equal to the gland thickness, may be required for Classes 1 and 3 seals.

8.3.3 Classes 1 through 4, split mechanical seals, shall be designed to operate under a minimum reverse differential pressure condition of 15-in. Hg (50.8 kPa).

8.4 The requirement for a balanced or unbalanced seal will vary dependent upon the combination of various design and performance factors. Balanced seals shall normally be supplied for pressures greater than 150 psi (1.03 MPa) unless the seal manufacturer provides alternative recommendations for specific applications. Selection of a balanced or unbalanced seal design must satisfy the performance requirements of Section 7.

8.5 The mechanical seal shall be designed to operate satisfactorily under the following:

8.5.1 Shaft sleeve surface finish for pusher-type seals shall be 32 rms (0.80 µm) maximum. Shaft sleeve surface finish for nonpusher seals shall be 64 rms (1.60 µm) maximum.

8.5.2 Shaft radial run-out 0.010 in. (0.25 mm) TIR maximum.

8.5.3 Shaft end-play maximum ±0.015 in. (0.38 mm).

8.5.4 Concentricity of stuffing box bore to shaft axis 0.005 in. (0.13 mm) TIR maximum. Gland plate design must accommodate eccentricity stated herein.

8.5.5 Perpendicularity of stuffing box face to shaft axis 0.003 in. (0.08 mm) TIR maximum.

8.6 Environmental Controls—Environmental control considerations, such as flushing, cooling, heating, and quenching shall be specified by the seal manufacturer.

9.1 Quality Systems—Mechanical seals shall be supplied in accordance with ISO 9001.

9.2 Responsibility for Inspection—Unless otherwise specified, the manufacturer is responsible for the performance of all inspection requirements. The manufacturer may use his own or any other facilities suitable for inspection. The purchaser (buyer) reserves the right to perform any of the inspections set forth in the specification where such inspections are deemed necessary to assure supplies and services conform to prescribed requirements.

9.3 Material Inspection—The manufacturer shall be responsible for ensuring that materials used are manufactured, examined, and tested in accordance with the specifications and standards as applicable.

9.4 Classification of Inspections—The inspection requirements specified herein shall be classified as follows:

9.4.1 Quality Conformance Inspection.

9.4.2 Inspection of Packaging.

9.5 Quality Conformance Inspection—All seal components shall be inspected in accordance with ASQC Z1.4 listing critical, major, and minor characteristics and type of inspection equipment used to determine said characteristics.

9.5.1 Acceptable Quality Level for Characteristics—The acceptable quality levels for characteristics, as per ASQC Z1.4, shall be as follows:

9.5.1.1 Critical—1.5 AQL
9.5.1.2 Major—2.5 AQL
9.5.1.3 Minor—4.0 AQL

9.5.2 Tests—All tests shall be performed in accordance with ASTM, ASME, or manufacturer’s standards as specified.

9.5.3 Test Data—All test data shall remain on file at the manufacturer’s facility for review by buyer upon request. It shall be retained in the manufacturer’s files for at least three years.

9.6 Inspection of Packaging:
9.6.1 Unit of Product—For the purpose of inspection, a completed package prepared for shipment shall be considered as a unit of product.

9.6.2 Sampling—Sampling for examination shall be in accordance with ASQC Z1.4. The AQL shall be 4.0 % defective.

9.6.3 Examination—Samples selected in accordance with 9.5.2 shall be examined for the following defects:

9.6.3.1 Materials, methods, container.
9.6.3.2 Strapping.
9.6.3.3 Consolidated seals not of like description.
9.6.3.4 Marking illegible, incorrect, incomplete, or missing.

9.7 Warranty:

9.7.1 Responsibility for Warranty—Unless otherwise specified, the manufacturer is responsible for the following:
9.7.1.1 All materials used to produce a unit.
9.7.1.2 Workmanship.
9.7.1.3 Manufacturer will warrant his product to be free from defect of workmanship.

9.8 Certification—When specified in the purchase order or contract, the purchaser (buyer) shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

10. Packing and Preparation for Delivery

10.1 Unit of Product—For the purpose of inspection, a completed package prepared for shipment shall be considered as a unit of product.

10.2 Packaging of Product for Delivery—Product should be packaged for shipment in accordance with standard industry practice.

10.3 Instructions—Instructions and manufacturer’s special provisions for handling shall be included in complete package.

10.3.1 Each of Classes 1 through 4, split mechanical seals, shall be supplied with detailed assembly and installation instructions.

10.3.2 All special or nonstandard tools and fixtures required to assemble and install the seal in the pump shall be identified and supplied with each seal package.

10.4 Any special packaging requirements for shipment or storage shall be identified in the ordering data. See Section 5.

10.5 Marking and Coding—When specified, a mechanical seal marking and coding system shall be used in accordance with Appendix X2.

11. Installation of the Seal Assembly

11.1 Seal suppliers shall provide instructions for each mechanical seal installation to include the applicable information required herein as a minimum.

11.2 Because of the variety of seal types and designs, Appendix X1 is provided for general guidance.

11.3 For specific detailed instructions, consult the seal supplier’s installation procedures. For reference to component identification terms, see Section 3 and Annex A1.
SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements established by the U.S. Navy, Commander Naval Sea Systems Command (NAVSEA), shall apply when specified in the contract or purchase order. When there is a conflict between the specifications and this Supplement S1, the requirements of Supplement S1 shall take precedence.

S1. Scope
S1.1 This supplementary requirement applies to mechanical end face seals for use in U.S. Navy shipboard pumps.
S1.2 Magnetic seals shall not be used.

S2. Referenced Documents

D 3951 Practice for Commercial Packaging
S2.2 Military Standards:5
MIL-S-901 Shock Tests, H.I. (High Impact); Shipboard Machinery, Equipment & Systems, Requirements for
MIL-P-16789 Packaging of Pumps, Including Prime Movers and Associated Repair Parts
MIL-R-83248 Rubber Fluorocarbon Elastomer, High Temperature, Fluid, and Compression Set Resistant
MS16142 Standard Dimensions for Gasket Seal Straight Thread Tube Fitting
MIL-STD-167-1 Environmental Vibration Testing

S3. Terminology:
S3.1 See Annex A1.

S4. Classification and Seal Arrangements:
S4.1 See Section 4.

S5. Design Requirements
S5.1 All mechanical seals shall meet the dimensional requirements from the applicable Tables S1-S4. Guidelines for seal/pump for S5 and S6 seals for cartridge and split mechanical seals are provided in Tables S5 and S6. Mechanical seals as shown in Table S1 Standard Long Mechanical Seals and Table S2 Standard Short Mechanical Seals, shall be of the single spring elastomeric bellows type. Slot details for antirotation pins applicable to Table S1 and Table S2 are shown in Fig. S1.
S5.2 Pusher type seals may be used for hydraulic oils, fuels, and lubricants.
S5.3 Mechanical seals to Tables S1-S4 shall be axially positioned or located on the shaft by positive means such as a stub, step, or shoulder on the shaft or a sleeve that is positively located on the shaft.
S5.4 Mechanical seals to Tables S1-S4 shall not be axially positioned by the use of set screws.
S5.5 Any special tools or spacers required to install and remove a mechanical seal shall be included with the seal.
S5.6 Mechanical seals supplied in accordance with Table S5 shall meet the following requirements:
S5.6.1 Table S5 mechanical seals may use setscrews to position the seal.
S5.6.2 A throttle bushing or secondary containment seal shall be used to limit leakage in event of seal failure. The diametrical clearance of the throttle bushing bore shall not be more than 0.025 in. for sleeve diameters up to 2.0 in. For larger diameters, the maximum diametrical clearance shall be 0.025 in. plus 0.005 in. for each additional 1.0 in. of diameter or fraction thereof. Mechanical seals used for lube oil and fuel services may use backup packing instead of throttle bushings.
S5.6.3 Non-sparking metallic assembly clips shall be used.
S5.6.4 Throttle bushing drain and seal flushing connections shall be provided with straight “O” ring fittings to MS 16142, minimum size ¼-in.
S5.7 Mechanical seals supplied in accordance with Table S6 shall meet the following requirements:
S5.7.1 No provision for back-up packing is required for split mechanical seals unless requested by the customer.
S5.7.2 Split mechanical seals shall not be used for fuel or lube oil service pumps.
S5.7.3 Mechanical seals supplied in accordance with Table S6 may leak at the seal faces during hydrostatic testing of the pump.
S5.8 Type E mechanical seals shall be the non-contacting design where the mating faces are designed to intentionally create aerodynamic or hydrodynamic separating forces to sustain a specific separation gap.
S5.8.1 Type E seals shall be used only on fuel/oil services with a shaft speed greater than 300 ft per min (fpm) measured at the shaft diameter.
S5.8.2 Nodular or graphitic ductile nickel cast iron mating rings allowed per Table S7 are not permitted in Type E seals.
S5.8.3 A self-contained gas seal support system (GSSS) shall be provided. The GSSS shall include check valve, gas regulator, pressure gage, and flowmeter. The GSSS components shall be enclosed in a box to protect from the elements. Flow and pressure indicators shall be visible from the outside of the box. GSSS shall be used to support the Type E seal during Section S7 testing. The GSSS shall undergo shock testing in accordance with MIL-S-901 and environmental vibration testing in accordance with MIL-STD-167-1.
S5.9 Unless otherwise specified, the seal manufacturer shall prepare drawings in accordance with ANSI Standards Y14.1, Y14.2, Y14.3, Y14.5, Y14.6, and Y14.26.3.
S5.9.1 Drawings shall be furnished under each contract or order unless the complete equipment covered by the drawings are identical in all respects to those previously submitted.
S5.9.2 Information intended for manufacturer’s use only shall be so designated.
S5.10 Drawings for each mechanical seal shall include a sectional assembly drawing and component detail drawings.
S5.10.1 Sectional assembly drawings shall include a sectional assembly with references to a parts list identifying materials for all individual parts.
F 1511 – 04
TABLE S1 Standard Long Mechanical Seal

NOTE 1—Standard (long) mechanical seal dimensions for Navy shipboard pump applications (low pressure, 150 psi (1.03 MPa) max, for new or
replacement applications).

S5.10.1.1 All running clearances shall be shown and shall be dimensioned and labeled as diametral clearances.
S5.10.1.2 Tightening torques with tolerances and thread lubrication requirements for threaded fasteners shall be shown on the drawing.
S5.10.1.3 Assembly drawings shall show, as a minimum, the dimensions shown on the applicable Tables S1-S4.
S5.10.1.4 Drawings shall specify the type, amount, and required use of lubricant.
S5.10.1.5 Drawings shall specify where there is an adhesive or other setting compound factory installed on the elastomer bellows or O-ring that seals between the mechanical seal and the impeller hub, shaft, or shaft sleeve.
S5.10.1.6 Drawings shall provide a description of any adhesive or setting compound identified in S5.10.1.5 including any time limits associated with the compound when present on a mechanical seal in storage and between initial wetting of that compound and the final positioning of the mechanical seal in the pump.
S5.10.2 When requesting qualification testing to satisfy Tables S1—S6, component drawings shall be submitted to NAVSEA for review and approval. Drawings to include dimensional details, manufacturing tolerances, and material specifications. Seal drawings to be used for NAVSEA verification only.
S5.10.3 Shock requirements are specified under Section S7.8 Shock Test.

S5.11 "J-seat" stationary ring designs shall be allowed for lube oil and fuel oil services.

S6. Materials

S6.1 The mechanical seal metal parts shall be supplied in accordance with Table S5.
S6.2 The primary seal ring shall be carbon-graphite, silicon carbide, or 6 to 10 % nickel-bound tungsten carbide. The mating ring face shall be 6 to 10 % nickel-bound tungsten carbide or silicon carbide and suitable for the liquid being pumped. Cobalt-bound tungsten carbide shall not be used. Nodular or graphitic ductile nickel cast iron may be supplied for lubricants and fuel oil service.
S6.3 Elastomers such as bellows, O-rings, friction rings, and so forth, furnished with seals supplied to the requirements of this Supplement S1 shall be made of fluorocarbon elastomer in accordance with MIL-R-83248, CL 1 or Cl 2, or Practice CTI–6 or P8412.
Alternative carbon graphite materials will be conditionally approved by NAVSEA for specific mechanical seal service. Approval for general service will be granted after seal qualification testing under this specification and after evidence of satisfactory shipboard service under equivalent operating conditions, is provided.

Wear Rate × Hours of Seal Life

---

6 Carbon graphite material shall be a manufacturer’s grade that has been tested and qualified for mechanical seal face service under the qualification tests required by this specification and has been documented as being in regular shipboard service under equivalent operating conditions.
S6 Split Seals shall use carbon graphite grades CTI–6 or P8412.
Alternative carbon graphite materials will be conditionally approved by NAVSEA for specific mechanical seal service. Approval for general service will be granted after seal qualification testing under this specification and after evidence of satisfactory shipboard service under equivalent operating conditions, is provided.
7 Ni-Resist or equivalent has been found satisfactory for this purpose.
D 1418 Class FKM, unless otherwise specified in the contract. Refer to Table 3 for general service applications and for alternative elastomers suitable for special requirements.

S6.4 On seawater pumps, the mechanical seal O-rings and other elastomers shall not be mounted on or come in contact with the impeller.
S6.5 All mechanical seals under this specification shall be certified to be free of functional mercury.

S7. Testing of Mechanical Seals

S7.1 The purpose of these test procedures is to develop a high confidence level that a Class 0 mechanical seal has a projected statistical life of 16,000 h under normal field service conditions.

S7.2 To qualify a mechanical seal design, NAVSEA\(^8\) will first conduct a technical evaluation, reviewing the manufacturer’s design for compliance with this specification, configuration, material and performance requirements. Subsequent to technical evaluation, the seal will undergo a performance evaluation, including:

(a) Technical evaluation, including:

\(6.5\)  The technical evaluation will include the following:

- Material and performance requirements.
- Subsequent to technical evaluation, the seal will undergo a performance evaluation, including:

- Test parameters monitored/measured:

<table>

</tr>
</tbody>
</table>

- S7.2.2.1 Testing, including qualification testing, of Classes 1 through 4 split mechanical seals shall be application specific, conducted under test conditions, which include the proposed operating conditions, and under a test schedule and performance requirements that have been agreed upon by the purchaser (buyer) and the manufacturer.

- S7.2.2.2 Type E seals shall be tested with 0.035 in. of axial endplay towards the driver end of the pump.

- S7.2.2.3 The 500 h endurance test for Type E seals shall be accomplished using a fluid with a viscosity of 100-500 SSU at start-up. Air shall be used as the barrier fluid.

- S7.2.2.4 Run-In Test:

<table>
<thead>

- S7.2.2.4 Type E seals shall undergo a seal recovery test. Test shall be performed in the following order:

1. 15 min at 300 fpm, 65 psig fluid pressure, 125 psig barrier pressure
2. 15 min at 300 fpm, 65 psig fluid pressure, disconnect air source, vent to atmosphere
3. 15 min at 800 fpm, 100 psig fluid pressure, 125 psig barrier pressure
4. 15 min at 800 fpm, 100 psig fluid pressure, disconnect air source, vent to atmosphere
5. 15 min at 300 fpm, 65 psig fluid pressure, 125 psig barrier pressure

At the end of the recovery test, there shall be no visible fluid leakage. Maximum barrier consumption rate shall be 0.47 nl/min or 1.0 scfh.

- S7.2.3 Any changes to a qualified mechanical seal shall be presented to the government buying activity for technical evaluation.

- S7.3 General Comments:

- S7.3.1 Data will be collected and entered on data sheets similar to those in Fig. S1 and Fig. S2.

- S7.3.2 Any problems encountered with the seals, installation, operation of the test fixture, or breakdowns of any kind, shall be recorded. This record shall include a statement of the problem, cause, running time meter reading at occurrence, and any other pertinent information.

- S7.3.3 All tests shall be performed in sea water using the same seal.

- S7.3.4 The test conditions shall be:

Fluid media: ocean water per Specification D 1141

- S7.3.5 Any seal shown in Table S1 and Table S2 successfully passing all tests will qualify any smaller seal of the same design up to but not including 1 in. (25.4 mm) smaller.\(^9\)

- S7.3.6 Test Facility—The test facility must be approved by NAVSEA\(^8\) before conducting the tests. Approval criteria will be based on information submitted by the facility demonstrating the capability to perform all tests indicated herein.

- S7.4 Pretest Inspection:

- S7.4.1 The seal shall be photographed as received from the manufacturer and examined for compliance. The mating surfaces shall be photographed to document the original unworn condition. All critical dimensions shall be measured and recorded. The width of the stationary mating ring and the height of the rotating primary seal nose shall be measured at 60° intervals. A reference point for these measurements shall be established to ensure that the posttest measurements are taken at identical locations. If a seal face is not measurable as an individual component, the manufacturer must provide the

---

\(^8\) Department of the Navy, Naval Sea Systems Command, NAVSEA, Arlington, VA 22242-5160.

\(^9\) Example: Successfully qualifying a 2.000-in. (50.8-mm) diameter seal would likewise qualify all seal sizes from 2.000 to 1.125 in. (50.8 to 28.5 mm).
information with photographs and certify the critical dimensions to 0.0001 in. (2.5 mm). Acceptance criteria: seal face wear rate must allow for an extrapolated service life of 16 000 h.

S7.4.2 The seal shall be examined for the following defects:
S7.4.2.1 Components missing or not as specified.
S7.4.2.2 Dimensions not as specified.
S7.4.2.3 Materials not as specified.
S7.4.2.4 Assembly incorrect.
S7.4.2.5 Workmanship not as specified.
S7.4.2.6 Configuration not in conformance with drawing.

S7.5 Run-In Test—After completion of the pretest inspection and seal installation, the test fixture shall be stabilized at the temperature, pressure, and speed specified for the test which shall be conducted immediately after the run-in test. The seal shall be operated for a period of 8 h continuously at test conditions and stopped. All the area on the test fixture that would collect fluid escaping past the seal shall be wiped clean.

FIG. S2 Mechanical Seal Test Data Sheet
and dry. The seal shall then be operated at the same test conditions for 20 min after which the leakage will be checked. Acceptance criteria: there shall be no apparent leakage.

S7.6 Hydrostatic Test—After successful completion of the prerequisites specified in the previous sections, the seal shall be subjected to 1.5 times the operational test pressure for a period of 5 min. During this test, the motor shall not be operated. Acceptance criteria: there shall be no measurable leakage.

S7.7 Operational Test:
S7.7.1 After successful completion of the hydrostatic test, the seal shall remain in the test fixture for the purpose of conducting the operational test.
S7.7.2 The seal test fixture shall be stabilized at the temperature, pressure, and speed specified. The operational test shall be for a period of 500 h running time with a minimum of 25 starts. Testing will be conducted at the neutral position and with axial and radial offsets, for the duration of the test sequences as listed in Table S6.
S7.7.3 During the operational test, the test fixture shall be monitored to record accurately the conditions of operation (pressure, temperature, speed, and so forth). Data shall be collected and the fixture examined at least twice daily. In addition to all measured data, the record shall indicate the seal leakage rate. Acceptance criteria: (1) There shall be no measurable leakage. (2) Seal face wear rate extrapolates to a minimum service life of 16 000 h.

S7.8 Shock Test:
S7.8.1 The governing document for the shock test shall be MIL-S-901. The seal test fixture, mounted on the anvil plate of a shock testing machine for lightweight equipment, shall be tested with water and shall be stabilized at room temperature, 30 psig (207 kPa) and 1800 or 3600 rpm. General requirements for the shock test are as follows:

<table>
<thead>
<tr>
<th>Grade</th>
<th>Class</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>I</td>
<td>C</td>
</tr>
</tbody>
</table>

All mounting and testing shall be performed in accordance with the requirements of MIL-S-901 pertaining to lightweight shock. Shock tests shall be conducted in the dynamic mode of operation. Seal leakage rate shall be monitored and recorded. Acceptance criteria: mechanical seal leakage rate shall not exceed five drops/min.
S7.8.2 A mechanical seal may also be qualified by testing in a pump unit as per MIL-S-901.

S7.9 Posttest Inspection—After completion of tests specified in S7.1 to S7.6, the seal shall be removed and all seal components closely examined. Record any unusual details. After removal, the seal shall be disassembled and an internal examination of the seal conducted as specified in S7.2.1. Wear shall be measured at 60° intervals relative to the reference point established during the pretest inspection. Photographs shall be used to document the worn condition of the seal. Average wear rate for the operational test shall be extrapolated to 16 000 h to determine the service life wear requirement. Examine and analyze the data obtained above and compare it to the data collected during the pretest inspection.

S8. Packaging and Marking
S8.1 The packaging and marking requirements specified herein apply only for direct U.S. Government acquisitions.
S8.2 Mechanical seals shall be preserved-packaged level A or C, packed level A, B, or C as specified, and marked in accordance with MIL-P-16789. Unless otherwise specified, package in accordance with Practice D 3951.

ANNEX

(Mandatory Information)

A1. TERMINOLOGY: DESCRIPTION OF TERMS RELATING TO MECHANICAL SEALS AND THEIR APPLICATION

A1.1 balanced seal—a mechanical seal designed to accommodate high stuffing box pressure with a decrease in seal face closing forces.
A1.2 barrier fluid—see buffer fluid.
A1.3 bellows—flexing seal elements:
A1.3.1 An elastomeric seal element with a full or half convolution that acts as a flexible secondary seal.
A1.3.2 Formed or welded metal seal element that provides spring load and a flexible secondary seal. See Fig. 1 and Fig. 4.
A1.4 buffer fluid—a lubricating liquid which is introduced between two seal assemblies to provide protection to the seal and/or the environment.
A1.5 bushing—a device used to restrict flow. See Fig. 1.
A1.6 cartridge seal—a completely self-contained assembly including seal, gland, sleeve, and drive collar or seal assembly & which can be assembled on to a pump as one unit.
A1.7 centrifugal separator—a device using centrifugal force to remove solids in a seal flushing liquid.
A1.8 diametral clearance—the difference between the diameters of two parts.
A1.9 double seal—two mechanical seals mounted back to back, or face to face, designed to contain a buffer fluid between the two seals. See Figs. 4-6.
A1.10 elastomer drive seal—a mechanical seal in which rotation of the seal assembly is accomplished through an elastomeric secondary seal.
A1.11 *end play*—movement along the axis or parallel to the center line of a shaft.

A1.12 *end face seal*—a mechanical seal that prevents leakage of fluids. Sealing is accomplished by means of a stationary seal ring bearing against the face of a rotating ring mounted on a shaft. Primary sealing is accomplished in a plane perpendicular to the shaft axis.

A1.13 *flush*—liquid that is introduced into the seal chamber in close proximity to the sealing faces.

A1.14 *gland gasket*—a static seal used between the gland plate and the pump casing.

A1.15 *gland plate*—a pressure-containing housing that is attached to the pump casing and holds the stationary part of the seal.

A1.16 *gland plate, solid*—a gland plate, according to A1.15, whose pressure retaining member is not radially split.

A1.17 *gland plate, split*—a gland plate that is split on a plane parallel to the axis of the shaft, with the result that the gland can be assembled around the shaft without requiring access over the end of the shaft.

A1.18 *inside mounted seal*—a mechanical seal assembly mounted inside the cavity which holds the fluid to be sealed.

A1.19 *light bands*—the horizontal distance between corresponding dark fringes on a reflective objective reference when viewed through an optical flat exposed to a monochromatic light source. For flatness measurement, the distance from one dark fringe to the next is 11.566 µin. for a helium gas light.

A1.20 *mating ring*—a precision lapped seal face normally mounted in a gland plate.

A1.21 *noncontacting seal*—a seal where the mating faces are designed to intentionally create an aerodynamic or hydrodynamic separating force to sustain a separation gap.

A1.22 *nonpusher seal*—a mechanical seal in which seal wear and end-play are compensated for by flexing a secondary seal element.

A1.23 *operating length*—the axial distance from the seal face to a reference plane. Also referred to as seal working height.

A1.24 *outside mounted seal*—a mechanical seal assembly mounted outside the cavity which holds the fluid to be sealed.

A1.25 *packing*—materials fitted into a stuffing box and compressed to form a seal between the shaft and the stuffing box bore.

A1.26 *positive drive*—mechanical means of providing rotational torque in a rotating seal element or preventing rotation in a stationary seal element by use of pins, tabs, keys, or set screws.

A1.27 *primary seal ring*—a precision lapped seal face which is held in the seal assembly.

A1.28 *pumping ring*—a simplified impeller within the seal cavity which circulates liquid for cooling.

A1.29 *pusher seal*—a mechanical seal with a dynamic secondary seal element.

A1.30 *quench*—a fluid that is introduced on the atmospheric side of the seal. Quench fluid is introduced through ports in the gland plate.

A1.31 *rotating seal*—a seal assembly in which the primary spring mechanism is rotated with the shaft.

A1.32 *seal cavity*—the space within a pump housing or gland between a stuffing box bore and a shaft in which a seal is installed.

A1.33 *seal nose*—the axial projection on the primary seal ring of an end face seal which forms the sealing surface.

A1.34 *secondary seal*—a device which provides dynamic sealing between the rotating element of a mechanical seal assembly and the shaft or sleeve. See Figs. 1 and 6.

A1.35 *shaft run-out*—twice the distance by which the center of the shaft is displaced from the axis of rotation.

A1.36 *shaft sleeve*—a cylinder placed over a shaft to provide protection of the shaft from wear and corrosion. It may be used to provide spacing for the impeller and as a device to provide a step in the shaft to achieve seal balance and/or positioning.

A1.37 *sleeve gasket*—a static seal used to prevent leakage between the shaft and the sleeve.

A1.38 *split seal*—a mechanical seal that has its elements split in a plane parallel to the axis of the shaft, with the result that instead of being continuous rings, they are essentially two semicircles.

A1.39 *split seal, partial*—a split mechanical seal in which only the rotating and stationary sealing face components and packing elements are split and replaceable by assembly around the shaft.

A1.40 *split seal, fully*—a split mechanical seal in which all of the rotating and stationary seal components are split, allowing the entire seal to be assembled around the shaft without requiring access over the end of the shaft.

A1.41 *static seal*—a seal between surfaces which have no relative motion.

A1.42 *stationary seal*—a seal assembly in which the primary spring mechanism does not rotate.

A1.43 *stuffing box pressure*—operating pressure for the mechanical seal.
A1.44 **tandem seal**—a multiple seal arrangement consisting of two seals mounted one after the other, with the faces of the seal assemblies oriented in the same direction. See Fig. 6.

A1.45 **throat bushing**—a bushing mounted at the bottom of the stuffing box that restricts flow into or out of the seal cavity. (See bushing.)

A1.46 **throttle bushing**—a bushing mounted in the gland to restrict flow of seal leakage or quench fluid to atmosphere. (See bushing.)

A1.47 **unbalanced seal**—a seal in which the total hydraulic pressure in the seal cavity acts on the faces of the mechanical seal.

**APPENDIXES**

*(Nonmandatory Information)*

**X1. SEAL ASSEMBLY INSTALLATION INSTRUCTIONS**

**X1.1 Before Installation of Seal:**

X1.1.1 Review the seal manufacturer’s installation drawings or instructions, or both.

X1.1.2 Verify proper equipment interface requirements as per 8.3.

X1.1.3 Keep the seal assembly clean and protected, especially the faces. If faces contain protective covering, leave the covering on until the last possible moment. If the rotary or stationary units must be touched, always cover the faces with a clean dry cloth.

X1.1.4 Check the secondary seals. Certain types require special lubricants or preparation before the placement in the equipment. PTFE wedges, V-, O-rings, and TFE-encapsulated O-rings may require special treatment before placement on shaft or in groove.

X1.2 **Seal Assembly Installation Procedures**—For cartridge or split seal designs, consult specific manufacturer’s installation instructions.

X1.2.1 Remove any loose matter in stuffing box and stationary cavity in gland plate with a cloth. Wipe these areas clean.

X1.2.2 Remove all burrs and sharp edges on shaft.

X1.2.3 Wipe shaft clean with a dry clean cloth.

X1.2.4 Lubricate the shaft and secondary seal.

X1.2.5 Elastomeric driven seals require the shaft to be lubricated with water or a very light grade oil. A nongranulated waterless soap is recommended. (Warning—Do not use petroleum jelly, TFE (tetrafluoroethylene), or silicone grease on an elastomer driven seal. EPR (ethylene propylene rubber) must not be lubricated with any petroleum base substance.)

X1.3 **Installing the Mating Ring:**

X1.3.1 Check to make sure that the cavity for the mating ring is clean and free of all foreign matter.

X1.3.2 Lubricate the mating ring static seal as in Paragraph X1.2.5.

X1.3.3 Carefully install mating ring by pressing it into the gland plate counterbore until it is bottomed and square.

X1.4 **Installation of the Seal and Mating Ring Assembly:**

X1.4.1 Slide the seal assembly on to the pump shaft. Make certain that it is properly positioned in relationship to the stuffing box and shaft. If set screws are used, verify installation reference to face of stuffing box. Tighten set screws.

X1.4.2 Before setting the seal compression, carefully and lightly wipe seal faces with a lint free cloth or remove face protective coverings.

X1.4.3 Install gland plate gasket.

X1.4.4 Bring gland plate into position and bolt it to the stuffing box face. (Warning—Excessive tightening of gland plate bolts could result in distortion and damage to the gland or the seal faces, or both.)

X1.5 **Reassemble the Pump.**

**X2. PART NUMBERING SYSTEM**

X2.1 Part numbers for mechanical seals shall include the number of this specification followed by a letter for the seal type and nine numerals to signify the grade, class, dimensions, metal component material, spring material, primary seal ring and mating ring material combinations, and elastomer component material. An example of this system is:

<table>
<thead>

</table>

X2.1.1 **Type:**

X2.1.1.1 A—Inside single mounted seals (4.1.1)

X2.1.1.2 B—Outside single mounted seals (4.1.2)
C—Double seals (4.1.3)
D—Tandem seals (6.2.1)
E—Special arrangements/applications vacuum or gas seal (4.1.6)

Grade:

1—Basic end face seal (4.1.7)
2—Cartridge seal (4.1.8)
3—Split seal (4.1.9)

Class:

0—All nonsplit seals (Grades 1 and 2) (4.1.10)
1—Partial split seal assembly, solid gland (4.1.11)
2—Partial split seal assembly, split gland (4.1.12)
3—Fully split seal assembly, solid gland (4.1.13)
4—Fully split seal assembly, split gland (4.1.14)

Seal Dimensions:

001 through 030—Commercial sizes starting at 0.375 in. and increasing in 0.125–in. size intervals to 4000 in.
101 through 130—Standard long mechanical seal (Table S1)
201 through 230—Standard short mechanical seal (Table S2)
301 through 304—Special cartridge seals Grade 2 (Table S3)
401 through 405—Special seals Grade 1 (Table S4)

Metal Component Material (Table 1 and Table S5):

1—316 stainless steel
2—NiCu, NiCr, NiCrMoCb, NiMo, NiMo (Alloy B), NiMo (Alloy C), NiCrFe, or NiCrMoCo
3—Special material

Spring Material (Table 1 and Table S5):

1—316 stainless steel
2—NiCu, NiCr, NiCrMoCb, NiMo, NiMo (Alloy B), NiMo (Alloy C), NiCrFe, or NiCrMoCo
3—Special material

Primary Seal Ring Material and Mating Ring Material Combinations (Table 2 and Table S5):

1—Carbon graphite and nodular or graphitic ductile nickel cast iron
2—Carbon graphite and tungsten carbide
3—Carbon graphite and silicon carbide
4—Siliconized carbon and tungsten carbide
5—Siliconized carbon and silicon carbide
6—Silicon carbide and tungsten carbide
7—Silicon carbide and silicon carbide
8—Tungsten carbide and tungsten carbide
9—Special materials

Elastomer Component Material (Table 3 and Table S5):

1—Fluorocarbon
2—Ethylene propylene
3—Nitrile
4—PTFE
5—Corrugated graphite ribbon
6—Chloroprene
7—Special material

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for
Fire Hose Nozzles

This standard is issued under the fixed designation F 1546/F 1546M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design, manufacture, and testing of fire hose nozzles intended for use with sea water or fresh water either in straight stream or adjustable spray patterns.

1.2 The values stated in SI units are to be regarded as the standard.

2. Referenced Documents

2.1 ASTM Standards:
   A 313/A 313M Specification for Stainless Steel Spring Wire
   A 580/A 580M Specification for Stainless Steel Wire
   A 582/A 582M Specification for Free-Machining Stainless Steel Bars
   B 117 Practice for Operating a Salt Spray (Fog) Apparatus
   D 395 Test Methods for Rubber Property—Compression Set
   D 412 Test Methods for Vulcanized Rubber and Thermoplastic Rubbers and Thermoplastic Elastomers—Tension
   D 572 Test Method for Rubber Deterioration by Heat and Oxygen
   D 1193 Specification for Reagent Water

2.2 NFPA Standards:
   NFPA 1963 Standards for Screw Threads and Gaskets for Fire Hose Connections

3. Terminology

3.1 Definitions:

3.1.1 ball shut-off—a spray nozzle configuration that stops the flow of water through the nozzle by rotating the ball through which the water flows so that the passage no longer aligns with the nozzle flow passage.

3.1.2 break apart—a feature that allows the nozzle tip to be disconnected from the nozzle body by virtue of a coupling identical to that on the hose end of the nozzle.

3.1.3 constant flow rate spray nozzle—an adjustable pattern nozzle in which the flow is delivered at a designed nozzle pressure. At the rated pressure, the nozzle will deliver a constant flow rate from straight stream through a wide angle pattern. This is accomplished by maintaining a constant orifice size during flow pattern adjustment.

3.1.4 constant pressure (automatic) spray nozzle—an adjustable pattern nozzle in which the pressure remains constant through a range of flows rates. The constant pressure provides the velocity for an effective stream reach at various flow rates. This is accomplished by means of a pressure-activated, self-adjusting orifice baffle.

3.1.5 constant/select flow rate feature—a nozzle feature that allows on-site adjustment of the orifice to change the flow rate to a predetermined value. The flow rate remains constant throughout the range of pattern selection from straight stream to wide angle spray.

3.1.6 free swivel coupling—a coupling between the nozzle and hose or between halves of a break-apart nozzle that is capable of being turned readily by hand; that is, a spanner wrench is not required to tighten the coupling to prevent leakage.

3.1.7 flush—a feature in a nozzle that allows the orifice to be opened so that small debris that might otherwise be trapped in the nozzle, causing pattern disruptions and flow variation, can pass through. When the flush feature is engaged, the nozzle pressure will drop and the pattern will deteriorate.

3.1.8 lever-type control—a control in which the handle operates along the axis of the nozzle.

3.1.9 pistol grip—a feature usually available as an attachment that allows a nozzle to be held like a pistol.

3.1.10 rated pressure—that pressure for which the nozzle is designed to operate at a specified flow rate(s).

3.1.11 rotational-type control—a control that rotates in a plane perpendicular to the axis of the nozzle.

4. Classification

4.1 Marine fire hose nozzles may be classified into four general construction types, as follows:

4.1.1 Type I—Pistol grip, lever-type control operated.
4.1.2 Type II—Nonpistol grip, lever-type control operated.
4.1.3 Type III—Break apart, pistol grip, lever-type control operated.
4.1.4 Type IV—Break apart, nonpistol grip, lever-type control operated.
4.2 Nozzle types may be subdivided into three general classes, as follows:
4.2.1 Class I—Constant flow rate.
4.2.2 Class II—Constant/selected flow rate.
4.2.3 Class III—Constant pressure.
4.3 Classes may be subdivided into two general sizes, as follows:
4.3.1 Size 38 mm, with free swivel base.
4.3.2 Size 64 mm, with free swivel base.

5. Ordering Information
5.1 The following shall be specified when ordering:
5.1.1 Quantity,
5.1.2 Type (see 4.1),
5.1.3 Class (see 4.2),
5.1.4 Size (see 4.3),
5.1.5 Material (see 6.1.2, 9.8.1 and 12),
5.1.6 Thread type.

6. Material and Manufacture
6.1 Materials:
6.1.1 All nozzle components and parts must be durable and demonstrate satisfactory operation during all performance tests in Section 9.
6.1.2 The nozzle body and any metal used in the construction of any part of the nozzle shall be corrosion resistant. Copper alloys containing more than 15 % zinc are prohibited in all parts that are in contact with the fluid flow. No aluminum alloys may be used except for nozzles being operated exclusively with fresh water. No ferrous material may be used except for the Type 300 series stainless steel for wire and springs in accordance with Specifications A 313/A 313M or A 580/A 580M and for screws and pins in accordance with Specification A 582/A 582M.
6.1.3 All nonmetallic materials or synthetic elastomers used to form a seal or gasket shall have the following properties:
6.1.3.1 uniform dimensions,
6.1.3.2 be of such shape, size, and resiliency as to withstand ordinary usage and foreign matter carried by water, including petrochemical solvents and high alkaline solutions such as those used for cleaning nozzles (see 6.2), and
6.1.3.3 be able to withstand ozone and ultraviolet light exposure if used on the external portion of the nozzle.
6.1.4 All materials shall have tensile set of not more than 5 mm as determined in accordance with 6.2.1, and compression set not more than 15 % as determined in accordance with 6.2.2.

6.2 Specific Requirements for Rubber Sealing Materials:
6.2.1 Tensile Strength, Ultimate Elongation, and Tensile Set Tests:
6.2.1.1 Tensile strength, ultimate elongation, and tensile set shall be determined in accordance with Test Methods D 412, Method A, except that, for tensile set determinations, the elongation shall be maintained for only 3 min, and the tensile set shall be measured 3 min after release of the specimen. The elongation of a specimen for a tensile set determination is to be such that the bench marks 25 mm apart become separated to a distance of 76 mm.
6.2.1.2 If a specimen breaks outside the bench marks, or if either the measured tensile strength or ultimate elongation of the specimen is less than the required value, an additional specimen shall be tested, and those results shall be considered final. Results of tests for specimens that break in the curved portion just outside the bench marks may be accepted if the measured strength and elongation values are within the minimum requirements.
6.2.2 Compression Set Test:
6.2.2.1 Type I specimens of the material shall be prepared and the test conducted in accordance with Test Methods D 395, Method B. The specimens shall be exposed for 22 h at 22°C.
6.2.3 Accelerated Aging Test:
6.2.3.1 Specimens shall be prepared in the same manner as for tensile strength and ultimate elongation and ultimate elongation tests, except for the bench marks 25 mm apart that shall be stamped on the specimen after the test exposure. The exposure shall be conducted in accordance with Test Method D 572.
6.2.3.2 All materials must retain not less than 70 % of the as-received tensile strength and ultimate elongation after the accelerated aging test.
6.2.4 Silicone rubber (rubber having polyorganosiloxane as its characteristic constituent) shall have a tensile strength of not less than 3.5 MPa and at least 100 % ultimate elongation as determined in accordance with 9.3.2.
6.2.5 Sealing material other than silicone rubber shall have a tensile strength of not less than 10 MPa and at least 200 % ultimate elongation as determined in accordance with 6.2.1.

7. Configuration
7.1 All nozzles shall consist of the following components and design:
7.1.1 Nozzle body,
7.1.2 Free swivel coupling,
7.1.3 Shutoffs,
7.1.4 Shutoff seats,
7.1.5 Shutoff handle,
7.1.6 Bumper guard,
7.1.7 Seals,
7.1.8 Flushing feature,
7.1.9 Piston grip (optional), and
7.1.10 Break apart feature (optional).
7.2 Nozzles shall be provided with a lever-type control shutoff handle which shall be in the closed position when the handle is closest to the discharge end of the nozzle. Lever-type control of the flow rate must also be by means of the shutoff handle.
7.2.1 The inside clearances of the shutoff handle shall be a minimum of 75 mm wide by 25 mm high.
7.2.2 The shutoff handle shall be of such a size that the operator’s hand in a fireman’s glove and closed on the handle does not interfere with the operation of the shutoff handle in any position.

7.3 Spray pattern adjustment shall be by means of rotational controls. Rotational controls shall traverse from a wide angle spray pattern to narrow angle, to straight stream in a clockwise manner when viewed from the hose coupling end of the nozzle. The wide and narrow angle spray patterns shall be enhanced with an impinging action by means of a minimum of one and a maximum of two rows of fixed or rotating teeth concentric to the discharge orifice.

7.4 Nozzles shall have a capability of clearing or flushing debris from the nozzle without shutting down the hose line. This may be accomplished either through the full open nozzle position or through a flush feature of the nozzle.

7.4.1 If used, the flush feature shall have a separate control, incorporate a detent, or shall required increased force to operate, to indicate to the firefighter when the flush feature is being engaged.

7.5 All features and controls shall be operable by one hand of the operator while the other hand is holding the nozzle.

7.6 A bumper shall be provided at the discharge end of the nozzle for protection against physical damage. The nozzle stem shall not extend past the bumper in any of the flow positions including flush.

7.7 The pistol grip, if one is provided, shall have four finger notches on the tip side and the minimum span and width shall be suitable for use with a hand wearing a typical fireman’s glove.

7.8 Couplings shall be of a free swivel type.

7.9 Each nozzle shall be provided with a resilient gasket fitted in the nozzle coupling recess. The gasket shall have dimensions in accordance with NFPA 1963. Type III and IV nozzles shall incorporate an additional gasket to accommodate the break-apart feature.

7.10 Nozzles for use with 38-mm hoses shall weigh not more than 5.9 kg. Nozzles for use with 64-mm hoses shall weigh not more than 4.53 kg.

7.11 Shutoff seats shall be self-adjusting or shall be adjustable without disassembly of the nozzle.

7.12 All features which incorporate a stop, detent, separate control, or increased force to engage shall be clearly labeled, including the open and shutoff positions, pattern selection, and flow rate selection.

8. Workmanship, Finish and Appearance

8.1 All parts and assemblies of the nozzle including castings, forgings, molded parts, stampings, bearings, machined surfaces and welded parts shall be clean and free from sand, dirt, fins, pits, spurs, scale, flux, and other foreign material. All exposed edges shall be rounded or chamfered.

9. Design Qualification Tests

9.1 Four first production run specimens shall be randomly selected and subjected to the tests described in 9.3 through 9.13 in sequential order.

9.2 The specimens shall exhibit no permanent deformation that interferes with their proper operation during any test.

9.3 Nonmetallic components shall be subjected to the following specific testing:

9.3.1 Aging Exposure:

9.3.1.1 Aging tests shall be performed before all other tests identified in this standard.

9.3.1.2 The specimens shall be subjected to air-oven aging for 180 days at 70°C and then allowed to cool at least 24 h in air at 25°C and 50 % relative humidity.

9.3.1.3 At the conclusion of the test, the specimens shall be inspected and all functions shall be operated to ensure they operate properly. Cracking, crazing, or any other condition that interferes with the proper operation of any specimen shall constitute failure of this test.

9.3.2 Ultraviolet Light-Water Exposure:

9.3.2.1 Nozzle designs with exposed nonmetallic parts shall be subjected to ultraviolet light and water for 720 h.

9.3.2.2 The ultraviolet light shall be obtained from two stationary enclosed carbon-arc lamps. The arc of each lamp is to be formed between two vertical carbon electrodes, 13 mm in diameter, located at the center of a revolvable vertical cylinder, 787 mm in diameter and 450 mm in height. Each arc is to be enclosed with a number PX Pyrex-glass globe.

9.3.2.3 The water shall conform to Type IV water in Specification D 1193.

9.3.2.4 The specimens are to be mounted vertically on the inside of the revolvable cylinder, arcing the lamps, and the cylinder continuously revolved around the stationary lamps at 1 revolution per minute. A system is to be provided so that each specimen in turn is sprayed with water as the cylinder revolves. During the operating cycle, each specimen is to be exposed to the light and water spray for 3 min and the light only for 17 min (total 20 min). The air temperature within the revolving cylinder of the apparatus during operations is to be maintained at 65°C.

9.3.2.5 At the conclusion of the test, the specimens shall be inspected and all functions shall be operated to ensure they operate properly. Cracking, crazing, or any other condition which interferes with the proper operation of any specimen shall constitute failure of this test.

9.4 Discharge Calibration Test:

9.4.1 Constant flow rate specimens shall flow the rated discharge, plus 10 %, minus 0 %, measured at rated pressure, through the entire range of pattern setting from straight stream to wide angle spray.

9.4.2 Constant/select flow rate specimens shall flow the rated discharge, plus 10 %, minus 0 %, measured at rated pressure, for each flow rate setting through the entire range of pattern setting from straight stream to wide angle spray.

9.4.3 Constant flow rate specimens and select flow rate specimens are to be installed on a piezometer fitting of the same size as the nominal inlet thread size, attached to a calibrated laboratory quality flow meter, and supplied with a source of pressurized water. The water flow rate in liters per minute is to be recorded through the full range of pattern selection.

9.4.4 Constant pressure specimens shall be tested beginning with the minimum rated flow. The pressure at this flow shall be recorded. The flow rate and nozzle pressure shall be monitored.
through the entire range of pattern selection from straight stream to wide angle spray. Any deviation over 2% in flow rate or pressure shall constitute failure of this test. The flow rate shall be slowly increased to the maximum rated flow while the pressure is monitored. At the maximum rated flow, the flow rate and pressure shall be monitored throughout the entire range of pattern selection. Any deviation over 2% in flow rate or pressure shall constitute failure of this test.

9.5 Flow Pattern Test:

9.5.1 Specimens shall develop discharge flow patterns varying from straight stream to wide angle spray while maintaining either constant flow rate or constant pressure.

9.5.2 The straight stream pattern setting shall provide a cohesive jet capable of delivering 90% of the rated flow within a circle 400 mm in diameter at a distance of 8 m from the nozzle.

9.5.3 The spray pattern settings shall provide a full and uniform spray pattern of small droplets, and the spray pattern adjustments shall provide spray pattern angles ranging from 25° for narrow angle spray through at least 120° for wide angle spray at maximum flow rate.

9.6 Flushing Test:

9.6.1 The specimens shall be held vertically, discharge end down, and the controls placed in the flush position. A 7-mm ball must pass through each specimen without changes in the flow of the stream to wide angle spray. Any deviation over 2% in flow rate and pressure shall be monitored throughout the entire range of pattern selection. Any deviation over 2% in flow rate or pressure shall constitute failure of this test.

9.7 Control Tests:

9.7.1 Lever-type controls:

9.7.1.1 Not more than 80 N nor less than 35 N shall be required to open or close the shutoff handle against a minimum of 700-kPa nozzle inlet pressure.

9.7.1.2 The specimens shall be mounted in the closed position and subjected to a static pressure of 700 kPa. A dynamometer, which records the maximum force reading, shall be attached to the shutoff handle, where the handle would normally be held during operation. The shutoff handle shall be moved from the fully closed to fully open position for the full range of pattern adjustment. The maximum force shall be recorded. Next, the specimens shall be placed in the full flowing position and the inlet pressure shall be adjusted to 700 kPa. With this new pressure adjustment, the dynamometer shall be used when moving the shutoff handle through the full range of positions and maximum force again measured and recorded. The maximum force recorded in both directions shall not be greater than permitted in 9.7.1.1.

9.7.1.3 The specimens shall be mounted without any water pressure being applied and the shutoff handle shall be placed in a closed position. The handle shall be moved from the closed position and the force required to move the handle shall be measured with the dynamometer. The force to move the handle shall not be less than permitted in 9.7.1.1.

9.7.2 Rotational-type controls:

9.7.2.1 Designs incorporating rotational controls shall have the torque required to rotate the sleeve determined while the specimen inlet pressure is 700 kPa.

9.7.2.2 A length of twine or string, not to exceed 2-mm diameter, shall be wrapped around each specimen at the point where each specimen would normally be held while rotating the sleeve. The string shall be of sufficient length to wrap around each specimen at least six turns. The first two turns will overlap the starting end of the string, and the balance of the turns will not overlap any other turn. A force gauge, which records the maximum force reading, will be attached to a loop in the free end of the string.

9.7.2.3 The sleeve shall be rotated by pulling the force gauge perpendicular to the center of the axis of each specimen. As the pattern sleeve rotates, the string will unwind, so that the force always remains tangential to the sleeve.

9.7.2.4 The sleeve shall be rotated in either direction through the entire range of rotation and the maximum torque shall be calculated. The torque shall not be more than 2 N-m nor less than 0.5 N-m.

9.7.2.5 Free swivel-type couplings shall be tested in accordance with 9.7.2.2 through 9.7.2.4. The force required to rotate each specimen once the swivel is tightened onto a coupling shall be at least 50 N not less than 5 N greater than the force required to rotate the specimen controls.

9.8 Corrosion Exposure:

9.8.1 This test is not required for aluminum nozzles because of the restriction on their use in fresh water service only.

9.8.2 The specimens shall be supported vertically and exposed to salt spray as specified by Practice B 117 for 120 h.

9.9 High Temperature Test:

9.9.1 The specimens are to be conditioned at 60°C for 24 h. Immediately after being removed from the heating chamber, the specimens shall be tested for proper function of all controls. There shall be no binding, sticking, or malfunction of any function.

9.9.2 Within 3 min of removal from the heating chamber, the specimens shall be subjected to the Rough Usage Test in 9.11.

9.10 Low Temperature Test:

9.10.1 The specimens are to be conditioned at −37°C for 24 h. Immediately after being removed from the cooling chamber, the specimens shall be tested for proper operation. There shall be no binding, sticking, or malfunction of any function.

9.10.2 Within 3 min of removal from the cooling chamber, the specimens shall be subjected to the Rough Usage Test in 9.11.

9.11 Rough Usage Test:

9.11.1 Two of the four specimens shall be connected to a dry hose and dropped twice from a height of 2 m onto a concrete surface such that the point of impact is on the lever and twice such that the point of impact is on a side 90° from the lever. The same two specimens shall then be dropped twice from a height of 600 mm such that the point of impact is squarely on the discharge end of the nozzle. The other two specimens shall be connected to a wet hose and placed in the shutoff position. The static pressure shall be increased to 700 kPa. The test from the 2-m height shall be repeated. Specimens equipped with
pistol grips shall also be dropped twice while unconnected so that the point of contact is on the grip.

9.11.2 Following the drop test, the specimens shall be examined for cracking, breaking, and deformation that interferes with their proper operation. Specimens developing cracks or broken sections or failing to operate properly are considered failed.

9.11.3 Following the drop tests, the specimens shall be subjected to the Leakage Test and Hydrostatic Pressure Test in accordance with 9.12 and 9.13, respectively.

9.12 Leakage Test:

9.12.1 The leakage test shall be conducted during the Hydrostatic Pressure Test.

9.12.2 At the point during the Hydrostatic Pressure Test in which the hydrostatic pressure is the greater of 4000 kPa or 1½ times the rated pressure, the shutoff shall be fully opened and closed. After the shutoff has been closed, the leakage shall be measured and recorded. The maximum leakage allowed through the discharge orifice is ½ mL per min. There shall be no leakage through any part of the specimens other than the discharge orifice.

9.12.3 The leakage shall be measured and recorded again when the specimens are subjected to the final hydrostatic pressure in 9.13. Increases in leakage shall not exceed 1 mL per min.

9.13 Hydrostatic Pressure Test:

9.13.1 The specimens shall be rigidly mounted in a closed position. The static pressure shall be increased to 350 kPa and held for 30 s. The static pressure shall be increased in 350-kPa increments and held for 30 s at each pressure to a maximum static pressure of 7000 kPa. The final pressure shall be held for 1 min without rupture of any specimen.

9.14 Operator Protection Test:

9.14.1 Each specimen shall be coupled to a hose and rigidly mounted at a height of 1 m to the center of the specimen body. The specimen may be slightly inclined to simulate the typical position during normal use. The pressure shall be increased to an inlet pressure of 700 kPa. The water must be clear and clean, such as that from a municipal water supply.

9.14.2 A cross or grid on which to mount radiometers shall be positioned 300 mm directly behind the specimen body. The structure shall be perpendicular to the vertical plane of the specimen.

9.14.3 Radiometers shall be mounted on the structure at a distance of 600 mm above the specimen, 300 mm to the right, 300 mm to the left, and 300 mm below the specimen.

9.14.4 A heat source, such as a grid, tree, or framework of natural gas nozzles, shall be positioned directly in front of the specimen. The heat source must be located at a horizontal distance from the specimen so that it will not be cooled when operating the specimen wide angle spray pattern.

9.14.5 The heat source shall be operated to obtain a heat flux value of at least 26 kW/m² measured by the radiometers. The specimen shall be set to the wide angle flow pattern, opened, and tested for each rated flow. The heat flux shall be recorded for each radiometer and the average calculated.

9.14.6 The average heat flux obtained during each test must be 5.7 kW/m² or lower, and no individual heat flux value may be greater than 8.0 kW/m².

9.15 Horizontal Distance:

9.15.1 The specimens shall be coupled to a hose, rigidly mounted at a height of 1 m in the open position. The flow pressure shall be set at 350 kPa.

9.15.2 The specimens shall be placed in the straight stream position. The specimens may be inclined to achieve the maximum reach. For 38-mm designs, the horizontal distance from the nozzle orifice to the center of the water pattern at its furthest point shall be at least 18 m. For 64-mm designs, this distance shall be at least 24 m.

9.15.3 The test shall be repeated with the inlet pressure increased to 700 kPa. For 38-mm designs, the horizontal distance from the nozzle orifice to the center of the water pattern at its furthest point shall be at least 27 m. For 64-mm designs, this distance shall be at least 36 m.

10. Quality Conformance Testing

10.1 Sampling for Quality Conformance Testing:

10.1.1 A quantity of completed specimens in accordance with Table 1 shall be randomly selected from each lot and subjected to the Discharge Calibration Test, Flow Pattern Test, and Leakage Test described in 9.4, 9.5 and 9.12, respectively. The Leakage Test shall be conducted using the rated pressure and the maximum leakage allowed through the discharge orifice is ¼ mL per min. If one or more defects are found in any specimen, the entire lot represented by the specimen shall be considered failed. If a lot is considered failed, the entire lot may be screened for the defective characteristic(s).

11. Certification

11.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples from each lot have been tested and inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

12. Product Marking

12.1 In addition to markings required by any other section, the name of the manufacturer, the manufacturer’s model number, the size (see 4.3), the thread type, and ASTM specification designation shall be marked on each nozzle. Furthermore, all nozzles manufactured with aluminum alloys shall be marked with the phrase “F.W. Only.” All required markings, whether embossed or attached, shall be permanent and legible.

13. Keywords

13.1 fire hose; fire protection; marine; nozzle; ship; shipboard equipment

Standard Guide Listing
Relevant Standards and Publications for Commercial Shipbuilding

This standard is issued under the fixed designation F 1547; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This guide is a compendium of relevant publications, standards, and other information related to commercial shipbuilding.

2. Significance and Use
2.1 This guide has been developed to aid naval architects, ship designers, material and equipment suppliers, buyers, ship owners and operators, and government agencies by providing pertinent information in one document that can be used during various stages of commercial shipbuilding. These stages include design, planning, purchasing, material fabricating, assembling, testing, quality assurance, and inspection.
2.2 This guide does not specify the use of a particular standard usage nor does it detail what the standard covers.
2.3 There may be more than one standard listed for a particular product, test, or specific application. However, this guide does not compare the different standards or specify which particular standard should be used.
2.4 A partial list of sources for obtaining various standards are included below. Other sources may be located by contacting various information centers such as those at ASTM, the National Institute for Standards and Technology (Codes Standards and Information), and the American National Standards Institute. Information is also available through various sites on the Internet World Wide Web (for example, http://www.webplus.net\Unisn). When ordering, organizations should consider obtaining the latest copies of standards as complete sets or portions of sets in whatever media are appropriate (for example, hard copy, CD-ROM, or microform since purchasing, quality assurance, and engineering departments are frequently looking for information about standards called out in contract specifications, and these standards vary from one contract to another. The abbreviations used in Table 1 are defined in 2.4. Some of the sources for ordering standards are:

- ABS Americas (ABS)
  A Division of the American Bureau of Shipping
  16855 Northchase Drive
  Houston, TX 77060

3. Standards and Publications

3.1 Table 1 lists standards and publications, subdivided into nine groups. If you do not find a standard in one group, check to see if it is in a related group.

4. IACS Member Societies

4.1 The International Association of Classification Societies (IACS) Member Societies are listed below. These Classification Societies have established IACS to promote the highest standards in ship safety and the prevention of marine pollution. IACS provides consultation and cooperation with IMO. The Member Societies are strictly bound by ISO based Quality Assurance Standards for Ship Classification and delegated statutory work.

Societies

American Bureau of Shipping (ABS)
ABS Plaza
16855 Northchase Drive
Houston, TX 77060
Tel: 281–877–6000

Bureau Verities (BV)
17 bis, Place des Reflets
La Defense 2
92040 Courbevoie, France
(Postal address: Cedex 44-92077 Paris-La-Defense, France)
Tel: (33-1) 42 91 52 91
Tlx: (842) 61538F BVSMG
Fax: (33-1) 42 91 52 93

China Classification Society (CCS)
40, Dong Huang Cheng Gen Nan Jie
Beijin 10006
China
Tel: (86-1) 513-6633
Tlx: (718) 210407 ZCBJ CN
Fax: (86-1) 513 0188

Det Norske Veritas (DNV)
Veritasveien 1
PO Box 300
N-1322 Hovik
Norway
Tel: (47-67) 57 99 00
Tlx: (856) 76 192 VERIT N
Fax: (47-67) 57 99 11

Germanischer Lloyd (GL)
Vorszetzen 32
PO Box 11 16 06
D-2000 Hamburg 11
Germany
Tel: (49-40) 361490
Tlx: (841) 212628 GLHH D
Fax: (49-40) 36149200

Korean Register of Shipping (KR)
1485-10 Seocho-Dong
Seocho-Ku, Seoul, Korea
PO Box 3229
Tel: (82-2) 5826001
Tlx: (787) 27358 K
Fax: (82-2) 5848813

Associates

Hravatski Registar Brodova (CRS)
Croatian Register of Shipping
Split 58000
Croatia

Fax: 585-746

Indian Register of Shipping
72 Maker Towers F, 7th Floor
Cuffe Parade
Bombay 400-005
Tel: (953) 83364 IRISIN
Fax: (91-22) 2181241

This ordering address applies to the following:
Code of Federal Regulations (CFR)
Department of Health and Human Services (DHHS)
4.2 Delegating Countries—The countries delegating statutory responsibilities to Classification Societies are listed in Table 2. We have received this information from only five of the IACS Member Societies. The abbreviations used are discussed at the end of Table 2.

5. IACS Member Societies with Offices in the United States—Publication Lists

5.1 ABS—American Bureau of Shipping & Affiliated Companies—Publications

5.1.1 For current prices and information concerning publications:

**ABS Americas:**

ABS Plaza
16855 Northchase Drive
Houston, TX 77060
Tel: 281–673-0700
Fax: 281–874-9551

**ABS Europe:**

ABS House, 1 Frying Pan Alley
London, E1 7HR England
Tel: (44-171) 247-3255
Telex: 865621
Fax: (44-171) 377-2453

**ABS Pacific:**

510 Thomson Road
No. 06-00, SFL Bldg.
Singapore 1129
Republic of Singapore
Tel: 65–353-5713
Telex: RS 34264
Fax: 65–353-3454

5.3.2.5 Certification Notes:
Quality Assurance Systems:
1.1 Conformity Certification Services—General Description, November 1988
1.2 Conformity Description, November 1988—Type Approval, January 1990
1.3 Conformity Certification Services—Quality System Certification, May 1990
1.5 Conformity Certification Services—Approval of Manufacturers, Metallic Materials, September 1990

Approval Schemes:
2.1 Approval and Survey Programs for Materials, October 1988
MAT 100—Approval of Manufacturers, Ferrous and Non-Ferrous Materials and Material Products
MAT 200—Manufacturing Survey, Ferrous and Non-Ferrous Materials and Material Products
MAT 300—Approval of Manufacturer and Manufacturing Survey, Mooring Equipment
MAT 400—Approval of Welding Consumables
MAT 500—Type Approval of Non-Metallic Materials and Material Products
MAT 600—Approval of Corrosion Protection Systems
2.4 Type Approval of Instrumentation and Automation Equipment, March 1988
2.5 Type Approval of Loading Instruments for Ships, June 1985
2.6 Certification of Offshore Mooring Chain, July 1985
2.7-1 Offshore Freight Containers, May 1989
2.8 On Board Stability Computers, February 1990
2.9 101 Type Approval, Valves, November 1991
102 Type Approval, Pipe Couplings, November 1991
103 Type Approval, Flexible Hoses of Non-Metallic Materials, November 1991
201 Approval Program, Approval of Hydraulic Cylinders
2.10 Diesel Engine Driven Power Plants—Certification, Testing, and Inspection, July 1991

Marine Operations:
3.3 Declarations on Lay-up of Ships, August 1983
3.4 Declarations on Preservation of Lay-up Ships, August 1976

5.3.2.6 Register Book
Det Norske Veritas’ Register Book (including 4 supplements)
5.3.2.7 Guidelines and Classification Notes:
Complete Volume (purchase basis)
Annual Subscription Fee (includes all new and revised notes issued)
Design and Classification of Roll-On/Roll-Off Ships, May 1980
Prevention of Harmful Vibration in Ships, July 1983
Internal Control, Mobile Offshore Units (Owners’ Control System) September 1983
Stability Documentation for Mobile Offshore Units Class and Statutory Services, November 1986
Documentation Required for SC Class, June 1988
Condition Assessment Program, September 1991
Safety and Quality Management, May 1992
Guidelines for Corrosion Protection of Ships, July 1992
4.1 Guidance Manual for Inspection and Repair of Bronze Propellers, October 1992
4.2 Guidance Manual for Inspection and Repair of Steel Propellers, October 1992
6.1 Fire Test Methods for Plastic Pipes, Joints, and Fittings, January 1987
7. Ultrasonic Inspection of Weld Connections, May 1980 (Reprint of November 1978)
10.1 Ships and Mobile Offshore Units, Alternative Survey Arrangements for Machinery and Automation Systems, August 1992
20.1 Stability Documentation—Ships (Newbuildings), February 1990
20.2 Lightweight Determination—Ships, February 1990
30.1 Buckling Strength Analysis, May 1992
30.2 Fatigue Strength Analysis for Mobile Offshore Units, August 1984
30.3 Spherical Shells Subjected to Compressive Stresses, October 1987
30.4 Foundations, February 1992
30.5 Environmental Conditions and Environmental Loads, March 1991
30.6 Structural Reliability Analysis of Marine Structures, July 1992
31.1 Strength Analysis of Hull Structures in Bulk Carriers and Container Ships, May 1980
31.2 Strength Analysis of Hull Structures in Roll-On/Roll-Off Ships, May 1980
31.3 Strength Analysis of Hull Structures in Tankers, October 1988
31.4 Strength Analysis of Main Structures of Column Stabilized Units (Semi-submersible Platforms), September 1987
31.5 Strength Analysis of Main Structures of Self-Elevating Units, February 1992
32.1 Strength Analysis of Rudder Arrangements, January 1984
32.2 Strength Analysis of Container Securing Arrangements, July 1983
41.2 Calculation of Gear Rating for Marine Transmission, August 1990
41.3 Calculation of Crankshafts for Diesel Engine, July 1988
42.1 Dual Fuel Arrangement for Diesel Engines with High Pressure Gas Injection, February 1989
5.3.2.8 Lists of Type Approved Manufacturers and Type Approved Products:
Approved Manufacturers:
100. Companies with Veritas Certified Quality Systems
101. Metallic Materials
Type Approved Products:
1. Nonmetallic Materials
2. Welding Consumables
3. Structural Equipment, Containers, Cargo Handling, and Securing Equipment
4. Machinery Components
5. Mechanical Equipment and Piping
6. Electrical Equipment and Systems
7. Instrumentation and Automation
8. Fire-Restricting Materials and Fire Technical Equipment
9. Drilling and Well Control Equipment
5.3.2.9 Rules for Other Objects:
Translation of Tentative Rules for the Construction and Classification of Vessels of Glass Reinforced Plastics (1972) Norwegian and English Editions
Tentative Rules for the Construction and Classification of Dynamic Positioning Systems for Ships and Mobile Offshore Units, 1977
Rules for the Construction and Classification of Floating Docks, 1977
Rules for Certification of Lifting Appliances, 1989
Rules for Certification of Freight Containers, 1981
Rules for Certification of Dividing Systems, 1988
Rules for Certification of Lifts, 1987
Rules for Certification/Classification of Submersibles, 1988
Rules for Lifeboats Based on SOLAS 1974 Amendment 83 Rev. Ch. 3, 1986

  - Fax: (212) 363–9610

**5.5.2 Lloyds Register (LR)—Publication List:**

- **5.5.2.1 Rules and Regulations (Marine):**
  - Rules and Regulations for the Classification of Ships 1993—Based on combination of long practical experience and advanced theory, the rules are constantly revised to take account of new developments in merchant shipbuilding. They are
intended primarily for use by naval architects, shipbuilders, and marine engineers. A complete set consists of seven separate parts contained in a Substantial binder.

The complete set, together with four-ring binder and LR's List of Approved Manufacturers of Materials, Recognized Proving Establishments, Class 1 Welding Firms and Firms Approved for Product Certification by Surveillance of Quality Systems.

All Parts from the Rules are available individually:

Part 3—Ship Structures—The basic structural philosophy of hull construction, longitudinal strength, aft end structures, superstructures, and so forth.

Part 4—Ship Structures—Hull construction requirements for specific ship-types—for example, tugs, ferries, bulk carriers, oil tankers, and containerships.

Part 5—Main and Auxiliary Machinery—Main and auxiliary machinery including shaft vibration and alignment, piping systems for oil and chemical tankers, and steering gear.

Part 6—Control, Electrical, Refrigeration, and Fire—Automation and control systems, electrical systems, refrigeration systems and fire prevention systems.

Part 7—Special Types—Highly specialized ships to which the format of the rest of the Rules cannot easily be applied—that is, nuclear ships; ships with installed process plant; fire fighting ships; dynamic positioning installed in ships; oil recovery ships; ship to shore ramps and linkspans; burning of coal in ships’ boilers; positional mooring systems and thruster assisted positional mooring systems.

Four-Ring Binder—With 55-mm capacity and blocked “Rules and Regulations.”

LR PASS (Plan Appraisal Systems for Ships)

Current Facilities

Rules programs for IBM/PC and compatible computers

Direct calculations programs for IBM/PC and compatible computers

Feedback and Improvement Procedure

Rules for Inland Waterway Ships—A complete set consists of the five parts contained in a substantial binder.

All parts are available individually:

Part 1—Regulations

Part 2—Materials for Ship and Machinery

Part 3—Ship Structure

Part 4—Ship Structure

Part 5—Main and auxiliary Machinery

Part 6—Control, Electrical and Fire

Binder—(With 55-mm capacity and blocked “Rules and Regulations.”)

Rules for Floating Docks 1987

Code for Lifting Appliances in a Marine Environment 1987—Requirements for ship derricks and deck cranes, offshore and floating cranes, lifts and ramps, launch and recovery systems for diving operations and mechanical lift docks.

5.5.2.2 Rules and Regulations (Offshore):

Rules and Regulations for the Classification of Mobile Offshore Units 1989—The Rules now appear in six Parts contained in a substantial binder (included in the price) and with Materials from the Rules and Regulations for the Classification of Ships.

Various Parts from the Rules are available:

Part 1—Regulations—Classification and periodical surveys.

Part 2—Materials—Conditions for manufacture, survey and certification, and requirements for high holding power anchors and special quality chain cable.

Part 3—Structure—Unit structural requirements, unit types, strength, mooring equipment, and steering arrangements.

Part 4—Stability, Watertight/Weather tight Integrity and Corrosion Control—Requirements for stability, load lines, watertight and weathertight integrity, guard rails, bulwarks and corrosion control.

Part 5—Main and Auxiliary Machinery—Main and auxiliary machinery including shaft vibration and alignment, piping systems, pressure vessels and steering gear.

Part 6—Control, Electrical, Hazardous Areas and Fires—Control systems, electrical systems, hazardous areas, fire fighting units and dynamic positioning systems.

Four-Ring Binder—With 40-mm capacity and blocked “Rules and Regulations.”

Rules and Regulations for the Construction and Classification of Submersibles and Underwater Systems 1989

Rules and Regulations for the Classification of Fixed Offshore Installations 1989—The rules are based on LR’s experience from the certification of over 600 platforms worldwide. Like all other LR rules, they are based on a mixture of experience and theoretical innovation. They are primarily intended for operators and designers in areas where national authorities have no requirements of their own. A complete set consists of eight parts contained in a binder.

All parts are available individually:

Part 2—Materials and Manufacturing Procedures—Material selection for both the jacket structure and machinery components. This part is accompanied by Materials of the Rules and Regulations for the Classification of Ships and includes a chapter covering Quality Assurance Scheme for the Construction of Fixed Offshore Installations.

Part 3—Environmental and Design Considerations—Approval of each installation is site specific including complete assessment of all environmental factors and ocean bed conditions. The jacket and module structures are examined for a variety of external loads imposed by the elements and the
distribution of weight on the platform. Also includes gravity
foundaiton design.

Part 4—Steel Structures—The structural arrangements of
each installation are independently examined and advice given
on acceptable analysis techniques, factors of safety and fatigue
design.

Part 5—Concrete Structures—All aspects of concrete struc-
tures including materials, fabrication, and assessment are
covered.

Part 6—Corrosion Protection—Active and passive cathodic
protection systems, coating and painting systems.

Part 7—Machinery and Process Systems—Regulations for
drilling and process equipment on platform and subsea, includ-
ing pressure vessels and pressure systems, heating, ventilation,
and air conditioning. Mechanical, electrical, control engineer-
ing, and hazardous areas are included.

Part 8—Fire and Safety Equipment—Passive and active fire
safety measures, both fixed and portable. Safety equipment
including lifesaving appliances and radio communications.

Four-Ring Binder—With 40-mm capacity and blocked
“Rules and Regulations.”

Container Certification Scheme 1988—Rules for the design,
construction, and inspection of general cargo containers, ther-
cmal containers (both insulated and refrigerated), tank contain-
ers and other portable tanks; container trailer/vehicle chassis;
in-service inspection of containers, tanks, and carrying tanks of
road containers; basic quality system requirements for manu-
facturer; ISO test procedures.

5.5.2.3 Approved Products:
LR-Type Approval System 1990—Advice to producers is
given in a series of documents which outlines the approval
procedure and test requirements to qualify for inclusion in the
list of LR-Type Approved Products.

LR-Type Approval System Procedure—describes system
operation.
LR-Type Approval System Test Specification No. 2—gives
marine environmental tests.
LR-Type Approval System Test Specification No. 3—gives
certain electrical product tests.
LR-Type Approval System Test Specification No. 4—gives
internal combustion engine tests.

List of Type Approved Products 1992—Includes details of
all products currently Type Approved in accordance with the
published Type Approval System. Available in four parts:
Part 1—Marine, Offshore and Industrial Equipment
Part 2—Electrical Equipment (Environmentally Tested)
Part 3—Control Equipment (Environmentally Tested)
Part 4—Fire Protection and Fire Fighting

List of Approved Type Tested Fuses (2nd Edition, 1987 plus
Addendum 1991)—Each entry in this publication carries
information essential in the selection of fuses for marine
installations and includes details of current ratings, together
with descriptions of fuse holders and bases.

List of Approved Type Tested Circuit Breakers (2nd Edi-
tion, 1987 plus Addendum 1991)—This publication has been
developed to assist in the selection of circuit breakers in
relation to their performance under short circuit conditions.

Approved Prefabrication Primers, Recognized Corrosion
Control Coatings, Accepted Fire Safe Paints 1992—This pub-
lication consists of two main sections covering prefabrication
primers and coatings approved for corrosion control in ships’
tanks. An additional section gives useful notes on procedures
for applying tank coatings. The publication lists approximately
400 products indexed under the name of the manufacturer.

List of Approved Welding Consumables for use in Ship
Construction 1992—This document, which is published annu-
ally, lists those welding consumables that have complied with
the approval requirements for use in ship construction set out
in LR’s rules. The document lists approximately 3500 consum-
ables in seven sections related to welding process and parent
material.

5.5.2.4 Approved Manufacturer:
List of Approved Manufacturers of Materials, Recognized
Proving Establishments and Class 1 Welding Firms 1992—
Also includes a list of manufacturers of steel, castings, forg-
ings, chain cable, wire ropes, and so forth.

5.5.2.5 Computer Data:
Rulefinder

5.6 Nippon Kaiji Kyokai (Class NK)—English Publications

5.6.2 Nippon Kaiji Kyokai (Class NK) Publication List:
5.6.2.1 Registers—Register of Ships (1995–96) with Quar-
terly Supplements—This book contains the principal particu-
lar and survey records of NK-classed ships.

5.6.2.2 Rules and Regulations/Guidances:

Regulations for the Classification and Registry of Ships (1997)
Conditions of Service for Classification of Ships and Registra-
tion of Installations (1997)
Regulations for the Issue of Statutory Certificates (1997)
Rules for Approval of Manufacturers (1997)
Rules for the Survey and Construction of Steel Ships
Part B—Class Surveys (1997)
Part C—Hull Construction and Equipment (1997)
Part U—Intact Stability (1997)
Part V—Load Lines (1997)
Part CS—Hull Construction and Equipment of Small Ships (1997)
Part D—Machinery Installations (1997)
Part H—Electrical Installations (1995)
Part K—Materials (1997)
Part L—Equipment (1997)
Part M—Welding (1997)
Part N—Ships Carrying Liquefied Gases in Bulk (1997)
Part P—Mobile Offshore Drilling Units, Workshops, and Special Purpose Barges (1997)
Part Q—Steel Barges (1997)
Part T—Submersibles (1997)
Rules for Installations of Ships
Rules for the Safety Equipment (1997)
Rules for the Radio Installation (1997)
Rules for Cargo Refrigerating Installations (1997)
Rules for Cargo Handling Appliances (1997)
Rules for Construction and Certification of Freight Containers (1994)
Rules for Floating Docks (1994)
Rules for High Speed Craft (1996)
Guidance for the Approval and Type Approval of Materials and Equipment for Marine Use (1997)
List of Approved Materials and Equipment (1997)

5.6.2.3 Other Publications
New Shipbuilding in Japan (issued quarterly)
Class NK Technical Bulletin Directory
Annual Report
Class NK Magazine

The following abbreviations in a flag administration’s box indicates that the Classification Society has been recognized and authorized to carry out all or some surveys and issue some international certificates under the above conventions. Please contact the Classification Society of your choice for more detailed information. Special authorization cases are not included. Classification Societies are not included if the country is not a signatory to the specific convention.

ABS—American Bureau of Shipping
BV—Bureau Veritas
DNV—Det Norske Veritas
GL—Germanischer Lloyd
LR—Lloyd’s Register
NK—Nippon Kaiji Kyokai
SOLAS—Safety of Life at Sea
MARPOL—International Convention for the Prevention of Pollution from Ships

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Designation: F 1548 − 01

An American National Standard

Standard Specification for the Performance of Fittings for Use with Gasketed Mechanical Couplings Used in Piping Applications

This standard is issued under the fixed designation F 1548; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification defines classification, materials, test requirements, inspection certification, marking and packaging of fittings for use with gasketed mechanical couplings complying to Specification F 1476.

2. Referenced Documents

2.1 ASTM Standards:

NOTE 1—See Table 1 for equivalency listing of applicable, equivalent specifications.

A 47 Specification for Ferritic Malleable Iron Castings
A 48 Specification for Gray Iron Castings
A 53 Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated Welded and Seamless
A 153 Specification for Zinc Coating (Hot-Dip) on Iron and Steel Hardware
A 216 Specification for Steel Castings, Carbon Suitable for Fusion Welding for High-Temperature Service
A 234 Specification for Piping Fittings of Wrought Carbon Steel and Alloy Steel for Moderate and High Temperature Service
A 312 Specification for Seamless and Welded Austenitic Stainless Steel Pipe
A 395 Specification for Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures
A 403 Specification for Wrought Austenitic Stainless Steel Piping Fittings
A 536 Specification for Ductile Iron Castings
B 26 Specification for Alumina-Silicon-Bronze Castings
B 75 Specification for Forged and Cast Ductile Iron
B 210 Specification for Aluminum and Aluminum-Alloy Drawn Seamless Tubes
B 369 Specification for Copper-Nickel Alloy Castings
B 580 Specification for Anodic Oxide Coatings on Aluminum
B 584 Specification for Copper-Alloy Sand Castings for General Applications
B 633 Specification for Electrodeposited Coatings of Zinc on Iron and Steel

8179 Ductile Iron Pipes—External Zinc Coating

3. Terminology
3.1 Definitions:
3.1.1 fabricated fitting—a fitting constructed by welding together sections of pipe or tube.
3.1.2 fitting—a device used in a piping system to change pipe direction, size, split or combine flows, or adapt to other joining methods.
3.1.3 grooved end—type of fitting or pipe end having a groove for use with grooved mechanical couplings (Type I) as defined in F 1476.
3.1.4 pipe—hollow tubular product conforming to Table 1 Specification Reference Nos. 19, 20, 22 and 13, Nominal Dimensions, or O.D. tube.
3.1.5 plain end—type of fitting or pipe end for use with a gasketed mechanical coupling (Type II) that is plain end as defined in Specification F 1476.
3.1.6 tangent—a section of straight pipe or tube integral to or welded to the end(s) of a fitting.
3.1.7 wrought fitting—a fitting made by shaping or shaping and welding.

4. Classification
4.1 These fittings are classified into the following design types:
4.1.1 Type I—Grooved end.
4.1.2 Type II—Plain end.

5. Ordering Information
5.1 Orders for fittings under this specification shall include the following:
5.1.1 Specification designation, title, number and year of issue.
5.1.2 Quantity.
5.1.3 Size and appropriate suffix (Example 8 in. IPS, 76.1 mm O.D.).
5.1.4 Fitting description (90° Elbow, Tee, Cross, etc.).
5.1.5 Type (I, II)—Type I must include groove style (that is, Standard, End Seal,\textsuperscript{12} AWWA Rigid, AWWA Flexible, or Copper).

5.1.6 Minimum pressure rating.

5.1.7 Material (ductile iron or steel, aluminum, copper nickel, copper, other, etc.) (see Section 6).

5.1.8 Finish (painted, galvanized, bare, plated, special coatings) (see Section 6).

5.1.9 Other requirements agreed to between purchaser and fitting manufacturer.

6. Materials and Manufacture

6.1 Ferrous Materials—Cast fittings shall be constructed of ductile iron in accordance with Table 1 Specification Reference 8 or 10 Grades 65–45–15 or 65–45–12 respectively or Malleable Iron in accordance with Table 1 Specification Reference 1 or steel in accordance with Table 1 Specification Reference 5 or Cast Iron in accordance with Table 1 Specification Reference 2. Wrought fittings shall be made in accordance with Table 1 Specification Reference 6. Fabricated fittings and tangents shall be constructed of steel in accordance with Table 1 Specification Reference 3.

6.1.1 Fitting shall be bare, coated with manufacturer’s standard preparation and paint, hot-dip galvanized in accordance with Table 1 Specification Reference 4 or other finish as agreed upon between purchaser and manufacturer.

6.2 Aluminum Alloy Materials—Fittings shall be constructed of aluminum alloy in accordance with Table 1 Specification Reference 12. Fabricated fittings shall be made from pipe in accordance with Table 1 Specification Reference 14.

6.2.1 Finish for aluminum alloy fittings shall be bare, anodized in accordance with Table 1 Specification Reference 16 or as otherwise agreed between purchaser and manufacturer.

6.3 Iron-Chromium-Nickel, Corrosion Resistance Materials—Fittings shall be constructed of iron-chromium-nickel alloy in accordance with Table 1 Specification Reference 11, or Table 1 Specification Reference 9. Welded tangents and fabricated fittings shall be in accordance with Table 1 Specification Reference 7.

6.3.1 Finish for iron-chromium-nickel shall be bare or as otherwise agreed between purchaser and manufacturer.

6.4 Copper or brass, cast fittings shall be constructed of brass in accordance with Table 1 Specification Reference 17. Wrought fittings shall be constructed of copper in accordance with Table 1 Specification Reference 13.

6.4.1 Finish for copper or brass fittings shall be bare or as otherwise agreed between purchaser and manufacturer.

6.5 Copper-nickel cast fittings shall be constructed of copper-nickel in accordance with Table 1 Specification Reference 15 as applicable.

6.5.1 Finish for copper-nickel fittings shall be bare or as otherwise agreed between purchaser and manufacturer.

6.6 Other Materials—Where other materials are required, the material, mechanical properties and finish of the products shall be as agreed upon by the fitting manufacturer and the purchaser.

6.7 Material Quality:

6.7.1 The material shall be of such quality and purity that the finished product shall have the properties and characteristics to meet the performance requirements of this standard.

6.7.2 The manufacturer is encouraged to use materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. The term “recovered materials” means: “Materials which have been collected or recovered from solid waste and reprocessed to become a source of raw material, as opposed to virgin raw materials.” Used or rebuilt products shall not be used.

7. Other Requirements

7.1 Design Requirements:

7.1.1 The design of the fittings may be qualified by mathematical analysis in accordance with piping codes agreed to by manufacturer and purchaser or by testing. Fittings that are tested shall be tested with gasketed mechanical couplings in accordance with the test requirements of Specification F 1476.

7.2 Qualification Requirements:

7.2.1 Mathematical Analysis:

7.2.1.1 A mathematical analysis, where appropriate, shall be performed as required by the governing piping code. Records of the analysis shall be available at the manufacturer’s facility for inspection by the purchaser.

7.2.2 Test:

7.2.2.1 The fittings shall be tested, where appropriate, with gasketed mechanical couplings in accordance with the requirements of Specification F 1476. Unless otherwise noted herein, all requirements of Specification F 1476 apply. Records of successful tests shall be available at the manufacturer’s facility for inspection by the purchaser.

7.2.3 Each type, pressure class, and material of fitting offered for sale must be qualified. Interpolation between qualified sizes is allowed as defined in Specification F 1476. Qualification of the fitting requires successful completion of the analysis or required testing. Each fitting design is only qualified for use with the GMC design on which it was tested or analyzed.

8. Dimensions, Mass and Permissible Variations

8.1 Fitting Dimensions—Fitting dimensions and tolerance shall be as specified by the manufacturer.

9. Workmanship, Finish and Appearance

9.1 All fitting surfaces shall be free from scale, blisters, fins, folds, seams, laps, burrs and cracks, which would affect the suitability for the intended service.

10. Inspection

10.1 Terms of Inspection:

10.1.1 Inspection of the fittings shall be in accordance with the manufacturer’s standard inspection procedure or as agreed upon between the purchaser and the manufacturer or supplier as part of the purchase contract.

10.2 Raw Material Inspection:

10.2.1 Raw material shall be inspected for compliance with its material specification.

10.3 Quality Conformance Inspection:

\textsuperscript{12} End seal is a registered trademark of the Victaulic Company of America.
10.3.1 Fitting samples shall be visually and dimensionally examined to verify compliance with the manufacturer’s appropriate drawings.

10.4 Process Control Inspection:

10.4.1 Fittings shall be inspected throughout the entire manufacturing and processing cycle. Methods of inspection shall be in compliance with manufacturer’s quality assurance procedures.

10.5 Inspection Records:

10.5.1 Inspection records shall be maintained by the manufacturer. The length of time on file shall be in accordance with the manufacturer’s quality assurance procedures.

11. Certification

11.1 Material Certification:

11.1.1 A certification of compliance shall be obtained from the materials supplier, when applicable. This certificate shall state that applicable requirements for the raw material have been satisfied.

12. Product Markings

12.1 Each fitting shall be marked with the manufacturer’s name or trademark, size, and markings traceable to the material and pressure rating.

13. Packaging

13.1 The fitting shall be boxed, crated, wrapped and otherwise protected during shipment and storage in accordance with manufacturer’s standard practice. Care shall be taken to properly protect the fitting from damage during shipment and storage.

14. Keywords

14.1 fitting; grooved; marine; ship; tangent
Standard Specification for Pressure-Reducing Valves for Steam Service

This standard is issued under the fixed designation F 1565; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers self-contained, internally operated, globe style, pressure-reducing valves for use in steam service. In these valves, the downstream pressure feedback is sensed by a spring-loaded diaphragm to position a pilot valve—the pilot valve uses the inlet steam pressure to position the main valve plug via an operating piston.

2. Referenced Documents

2.1 ASTM Standards:

3. Terminology

3.1 **accuracy of regulation**—the amount by which the downstream pressure may vary when the valve is set at any pressure within the required set pressure limit and is subjected to any combination of inlet pressure, flow demand, and ambient temperature variations, within the specified limits.

3.2 **design pressure and temperature**—the maximum pressure and temperature the valve should be subjected to under any condition. These are the pressure and temperature upon which the strength of the pressure-containing envelope is based.

3.3 **hydrostatic test pressure**—the maximum test pressure that the valve is required to withstand without damage. Valve operation is not required during application of this test pressure, but after the pressure has been removed, the valve must meet all performance requirements.

3.4 **lockup pressure**—the outlet pressure delivered by a pressure-reducing valve under shutoff conditions (that is, when the flow demand is reduced to a point where it is equal to or less than the allowable leakage as defined in 8.3).

3.5 **nominal pressure**—the approximate maximum pressure to which the valve will be subjected in service under normal conditions.

3.6 **set pressure**—the downstream pressure which the valve is set to maintain under a given set of operating conditions (that is, inlet pressure and flow). Ideally, the valve should be set at downstream pressure approximately equal to the mid-point of the set pressure limits (defined in 3.7).

3.7 **set pressure limits (range of set pressure adjustment)**—The range of set pressure over which the valve can be adjusted while meeting the specified performance requirements.

4. Classification

4.1 Valves shall be of the following compositions and pressure ratings, as specified (see Section 5 and 6.1.7). The pressure-temperature ratings shown below are applicable to the pressure-containing components of the valve. See Fig. 1 and Fig. 2.

4.1.1 **Composition B**—1¼ % chromium, ½ % molybdenum [maximum temperature 1000°F (see 6.1.7)].

4.1.2 **Composition D**—carbon steel [maximum temperature 775°F (see 6.1.7)].

4.3 **Pressure Ratings**—These shall conform to ASME Class 150, Class 300, Class 600, or Class 1500.

5. Ordering Information

5.1 Ordering documentation for valves under this specification shall include the following information, as required, to describe the equipment adequately.

5.1.1 ASTM designation and year of issue.

5.1.2 Valve specification code (see 6.1.14).

5.1.3 Composition and pressure rating required (see Section 4).

5.1.4 Trim materials where specific requirement is known (see Table 1, Footnote B, Note 2).

5.1.5 Whether internal or external reduced pressure sensing line is required (see 6.1.2.1).

5.1.6 Accuracy of regulation required if other than listed in 7.2.

5.1.7 Minimum and maximum inlet steam pressures (psig) (see 7.3 and S1.5).

5.1.8 Maximum inlet steam temperature (°F) (see S1.5).

5.1.9 Range of set pressure adjustment for valves, if other than listed in 7.4.

5.1.10 Maximum and minimum capacity required lb/hour.

5.1.11 Special tools, if required (see 6.1.15).

5.1.12 Supplementary requirements, if any (see S1 through S4).

6. Valve Construction and Coding

6.1 Valves shall incorporate the design features specified in 6.1.1-6.1.14.

6.1.1 **Materials of Construction**—Materials shall be as specified in Table 1. All materials shall be selected to prevent corrosion, galling, seizing, and excessive wear or erosion where applicable. Clearances shall prevent interference as a result of the thermal expansion. Cadmium plating is prohibited.
6.1.2 General Requirements:

6.1.2.1 Valves will be operated, maintained, and repaired on board ships and shall emphasize simplicity, maintainability, ruggedness, and reliability. Design shall permit access for adjustment and repair when working from either side of the valve and without requiring removal of the valve body from the line. Valves shall be of the self-contained, internal-operated type as described in 1.1.

6.1.2.2 The operating piston shall be separate from the main valve and fitted with one or more piston rings. The design shall prevent water buildup on the piston. The piston shall operate within a separate hardened steel cylinder liner located in the valve body so that removal of the valve bonnet provides access to the top of the piston assembly. The cylinder liner shall be held in place by way of the bonnet bolting or shall be permanently fabricated into the body. The requirement to locate the cylinder liner in the body may be waived where it is shown that an alternative location provides a satisfactory maintenance configuration. Pilot valve and diaphragm chambers shall be self-draining. The pilot valve shall be single seated with integral stem. The valve shall be controlled by a spring-referenced metal diaphragm and shall open against high pressure. A return spring shall keep the pilot valve in contact with the diaphragm at all times. The diaphragm shall not travel through center during any phase of operation. Edges contacting the diaphragm shall be rounded to prevent wear and damage. The diaphragm shall not travel against high temperature of the spring. A return spring shall keep the pilot valve in contact with the diaphragm at all times. The diaphragm shall not travel through center during any phase of operation. Edges contacting the diaphragm shall be rounded to prevent wear and damage. The diaphragm shall not travel against high pressure.

*If desired by the manufacturer, the higher grade bolting materials may be used in lower temperature categories (for example, Specification A 194/A 194M, Grade 4 may be used for Composition B, and so forth) and also higher grade body materials for Composition B and D valves (for example, Specification A 182/A 182M, Grade F 22 for Composition B, and so forth).

**Trim materials—Unless otherwise specified (see 5.1), the valve manufacturer shall select from the categories listed below the trim materials best suited to meet the requirements.

1. Main valve trim materials. Main valve trim (defined as consisting of the seat or seat ring and plug and the guide posts and bushings) materials shall be selected from the following:
   a) Stellite—Trim to be Stellite.
   b) Hardened corrosion-resistant steel—Hardened corrosion-resistant steel plug (400 series or 17-4 PH) and Stellite seat or seat ring. Guiding surfaces to be hardened corrosion-resistant steel or Stellite.
   c) Where Stellite is used, it shall consist of either wrought Stellite 6B, cast Stellite 6, or an inlay of Stellite (not less than %2-in. thickness for main seat and disk surfaces). Where inlays are used, welding rods shall be in accordance with Type MIL-RCr-A or MIL-R-17131.

2. Pilot valve trim materials. Pilot valve trim (defined as consisting of the seat, valve, and guiding surfaces) shall be made from one or a combination of the following materials:
   a) 400 series or 17-4PH corrosion-resistant steel-hardened.
   b) Stellite.
   c) Spring materials—Where the working temperature of the spring will exceed 600°F, either Inconel X-750 or A-286 alloy steel shall be used. Where the working temperature of the spring exceeds 450°F but not 600°F, Inconel 600 or tungsten tool steel may also be used. Where the working temperature of the spring will not exceed 450°F, 300 series corrosion-resistant steel may be used.

</tbody>
</table>

6.1.4 **Interchangeability**—Valve design shall permit interchangeability without individual modification of like parts between all valves. Each part shall have part number identity and shall be replaceable from stock or the manufacturer on a nonselective and random basis. With the exception of matched parts, parts having the same manufacturer’s part number shall be directly interchangeable with each other with respect to installation (physical) and performance (function). Physically interchangeable assemblies, components, and parts are those that are capable of being readily installed, removed, or replaced without alteration, misalignment, or damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.1.5 **Springs**—Springs shall not be fully compressed during any normal operation or adjustment of the valve. The working stress shall be such that relaxation shall not exceed 5% over a 1000-h period at the nominal operating temperature. Spring ends shall be squared and ground.

6.1.6 **Threads**—Threads shall conform to ASME B1.1. Where necessary, provisions shall be incorporated to prevent accidental loosening of threaded parts. Pipe threads shall not be used. ASME B18.2.1 hex-head standards shall be used.

6.1.7 **Pressure-Temperature Ratings**—Valve pressure-temperature rating shall be in accordance with ASME B16.34 except for maximum allowable temperature. Maximum temperature limitations shall be as follows:

- **6.1.7.1 Composition B**—1000°F.
- **6.1.7.2 Composition D**—775°F.

6.1.8 **End Preparation**—Valves shall be furnished with flanged ends in accordance with ASME B16.5. Flanges shall be cast or forged integral with the valve body, and the inlet and outlet flanges shall be of the same size and pressure rating.

6.1.9 **Bonnet and Bottom Cover Joints**—Bonnet and bottom cover (where applicable) shall be flanged for attachment to the body. Joints shall be secured by either of the following:

- (a) Through-bolts or studs threaded the entire length and fitted with a nut on each end. Threads on bolts, studs, and nuts shall be Class 2 fit in accordance with ASME B1.1.
- (b) Studs with interference fit at the tap end sufficient to preclude inadvertent backing out and a Class 2 fit at the nut end.

Bonnet and bottom cover shall be located by body guiding (that is, a close tolerance fit between machined diameters on the body, bonnet, and bottom cover) rather than depending on studs or bolts for location. Spiral wound gaskets shall be fully retained, and the joints shall have metal-to-metal take-up to provide controlled compression of the gaskets. To assure easy gasket removal, not more than two gasket-retaining faces for each gasket shall be formed on a single part. Joint design shall assure parallel alignment of the guide bushings. Sufficient bolting area shall be provided to maintain metal-to-metal make-up over at least a three-year period. Bearing surface of nuts and their respective surfaces on the valve shall be finished machined.

6.1.10 **Body Construction**—Valve bodies shall be machined from a one-piece casting or forging and shall be of basic globe configurations with in-line inlet and outlet ports. Steam lines, except for the external downstream pressure sensing line (where used), shall be internally ported in the body and bonnet. Body passages shall produce gradual changes in flow direction so as to reduce any effects of concentrated impingement and 90° turns. In portions of the valve subject to velocity increases and flow direction changes, such as immediately downstream of the seat, the design shall eliminate direct impingement against the walls at close range.

6.1.11 **Control Connections**—Where external downstream sensing is used, a ½-in. iron pipe size (i.p.s.) flanged connection, which is either cast or forged integral with the body or bonnet or welded, shall be provided.

6.1.12 **Internal Trim**—Internal trim (except welded or brazed-in seat rings) shall be readily replaceable without requiring removal of the valve body from the line. The main plug or disk shall be single seated. Guiding of the plug or disk shall prevent binding or seizing and ensure proper seating under all design conditions. This requirement shall be maintained with interchangeable parts and under any tolerance stack-up condition.

6.1.13 **Set Point Adjustment**—Means shall be provided for adjusting the set point through the specified range, with the valve under pressure. The adjusting or loading device shall be safeguarded against accidental change in set point.

6.1.14 **Valve Specification Coding**—Basic valve design features shall be specified and recorded using the following valve coding system. The valve specification code contains four fields of information, which describe the construction features of the valve. Each of these four fields are further assigned their respective codes per Tables 2-5.

6.1.15 **Maintainability**—Maintenance shall require standard tools to the maximum extent possible. Any special tools, which are not commercially available, required for adjustment or repair shall be identified and shall be supplied as part of the valve, if specified in the ordering information (see Section 5).

7. **Performance**

7.1 All valves shall meet the requirements of 7.1.1-7.8.

7.1.1 **Springs**—Springs shall not exhibit a set in excess of 0.005 in./in. of travel. Springs shall not be fully compressed during any normal operation or adjustment of the valve. Springs shall not be fully compressed during any normal operation or adjustment of the valve. Springs shall not be fully compressed during any normal operation or adjustment of the valve. Springs shall not be fully compressed during any normal operation or adjustment of the valve.

7.2 Accuracy of Regulation—The valve shall have an accuracy of regulation (see 3.1) of ±5% or ±2 psi, whichever is greater unless otherwise specified in 5.1.

7.3 Capacity—The actual steam flow capacity required, in pounds per hour (lbs/hour), based on the minimum inlet pressure and highest reduced outlet pressure setting under which the valve will be required to operate, shall be as specified (see 5.1). The valve shall meet the specified capacity requirement, or any intermediate capacity requirements down to 10% of the specified capacity requirement, and shall operate without hunting, chattering, or excessive noise or vibration, or exceeding the accuracy of regulation specified in 7.2, under all specified operating conditions.

7.4 Range of Set Pressure Adjustment (Set Pressure Limits)—Valve shall be capable of meeting the performance requirements specified in 7.2 and 7.3 when set at any point within the required range of set pressure adjustment. Unless otherwise specified (see 5.1), valve set pressure shall be adjustable over a range specified in Table 5.

7.5 Seat Tightness—With a dead-end downstream volume not exceeding the volume represented by 100 diameters of downstream pipe, any steam leakage from the inlet to the outlet of the valve shall be limited below a value which will cause a discharge pressure buildup of 10 psi in a 1-h period.

7.6 External Leakage—There shall be no external leakage which can be detected by use of a mirrored surface (for steam) or bubble fluid (for air).

7.7 Mechanical Shock and Vibration—Valve shall meet the mechanical shock requirements defined by Grade A, Class I of MIL-S-901, the HI-shock test guidance of MIL-STD-798, and the environmental vibration requirements defined by Type I of MIL-STD-167-1 up to and including 33 Hz.

7.8 Endurance—Valves shall be capable of passing the 5-h endurance test as outlined in S1.1.6.

8. Tests Required

8.1 Each production valve shall pass the tests outlined in 8.2-8.5.

8.2 Nondestructive Tests—Nondestructive tests shall be as specified in NAVSEA S9074–AR-GIB-010/278 and in accordance with NAVSEA T9074–AQ-GIB-010/271. Acceptance criteria shall be in accordance with MIL-STD-178. This shall include RT, MT/PT, pressure, and visual testing as delineated in the above specifications.

8.3 Hydrostatic Test—Valves shall be tested in accordance with ASME B16.34. There shall be no external leakage, permanent distortion, or structural failure.

8.4 Seat Tightness Test (Dead-End Test)—Using steam or air, with an inlet pressure equal to the nominal rating, the outlet pressure in a dead-end volume representing not more than 100 diameters of the downstream pipe shall not rise more than 10 psi in a 1-h period.

8.5 External Leakage Test—Pressure containing parts shall be tested with steam or air to the maximum working pressure to check for external leakage. There shall be no external leakage which can be detected by use of a mirrored surface (for steam) or bubble fluid (for air).

9. Marking

9.1 Body Markings—The manufacturer’s name or trademark and the body material composition shall be cast or forged integral with the valve body. The size, rating, and a flow arrow shall be cast or forged integral with the valve body or die stamped on raised metal pads (1/8-in. added wall thickness minimum), or stamped on the outside diameter of the flanges.

9.2 Identification Plates—An identification plate of corrosion-resistant metal shall be attached to the valve and shall list the following:

9.2.1 Manufacturer’s name.
9.2.2 Valve specification code.
9.2.3 Set pressure range.
9.2.4 ASME pressure class rating.
9.2.5 Manufacturer’s model or part number.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied. This system shall also ensure that all valves will perform in a similar manner to those representative valves subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

11. Keywords

11.1 marine; ship; steam; valves
SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1, S2, S3, or S4 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. Initial Qualification Testing

S1.1 Qualification tests shall be conducted at a facility satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.1.1 through S1.1.10 and delineated in the ordering data (see outline of tests in Table 2). The tests may be conducted on representative valve sizes and pressure classes to qualify all sizes and pressure classes of valves provided the valves are of the same type and design. Evidence of prior approval of these tests is acceptable.

S1.1.1 Qualification Test Sample—A sample valve(s) shall be submitted for each pressure rating for which qualification approval is desired (for sample size(s) required for shock qualification, see S1.1.7). Qualification approval, based on the examination and test of the sample, will then apply to all sizes of that pressure rating covered by this specification (see S1.1.1.1). Cross-sectional assembly drawings of all sizes of that type and rating shall be submitted with the test valve.

S1.1.1.1 Upon specific approval by the customer, valves of other sizes may be tested. Use of only one valve size for qualification of a type and rating under this specification only applies where the test valve is representative of the basic design features of all sizes of the pressure rating for which qualification is desired. The customer reserves the right to determine what are significant variations requiring separate qualification testing.

S1.1.2 Examination Before Testing—Upon receipt of the qualification test sample, the sample valve(s) shall be disassembled and visually and dimensionally examined to determine conformance with the requirements of this specification and complete dimensional conformance to the detailed engineering drawings.

S1.1.2.1 Upon satisfactory completion of the examination specified in S1.1.2, the valve(s) shall be tested as specified in S1.1.3 through S1.1.9.

S1.1.3 Spring Test—The spring from the disassembled sample valve shall be visually and dimensionally examined as follows:

S1.1.3.1 The free spring length shall be measured and an allowance of 0.010 in. per each inch of free spring length calculated. Fraction of inches of free spring length shall be prorated and added to the calculations for allowance.

S1.1.3.2 The spring shall be compressed to its working height and released.

S1.1.3.3 Ten minutes after release, the spring shall be measured again.

S1.1.3.4 The spring shall not exhibit a set in excess of the allowance calculated in S1.1.3.1.

S1.1.4 The valve shall be subjected to and must pass the tests outlined in 8.1-8.4 (nondestructive test, hydrostatic test, seat tightness test, and external leakage test).

S1.1.5 Performance Test—The performance tests shall be conducted with the valve set at the upper, mid-point, and lower setting of the adjustable set pressure range required by the application (see 5.1). Test medium shall be steam. The maximum inlet temperature, the range of operating inlet pressures, and the maximum flow capacity required shall be as specified (see 5.1) to meet the application requirements. The required accuracy of regulation shall be maintained. There shall be no evidence of hunting, chattering, or any other unstable or unsatisfactory operation of the valve during any portion of the required operational range of the valve.

S1.1.5.1 The flow shall be varied from lock-up to the maximum flow rating of the valve and back (see 5.1). This test shall be conducted under the following sets of conditions:

- Condition (a) Max inlet pressure − lowest set pressure.
- Condition (b) Min inlet pressure − lowest set pressure.
- Condition (c) Min inlet pressure − mid-point set pressure.
- Condition (d) Max inlet pressure − mid-point set pressure.
- Condition (e) Max inlet pressure − highest set pressure.
- Condition (f) Min inlet pressure − highest set pressure.

During each group of test conditions (that is, (a) and (b), (c) and (d), and (e) and (f), no alteration shall be made to the set pressure adjustment, or any other portion of the valve. The duration of the test at each condition shall not exceed 30 s.

S1.1.6 Endurance Test—The valve shall be subjected to a 5-h operational test to check functioning and performance. Test medium shall be steam. The 5-h test shall include not less than 25-min aggregate time within each of the following specific flow ranges: 95 ± 5 % maximum rated flow; 25 ± 3 % maximum rated flow; and 10 ± 2.5 % maximum rated flow.

The valve shall operate at all times without evidence of instability, without allowing delivered pressure to vary from specified limits, and without requiring any maintenance, repair, or adjustment effort. At the successful completion of the 5-h test, the valve shall be removed and completely disassembled. All parts shall be examined for signs of excessive wear or any other condition indicating impending failure or malfunction. Any such condition shall constitute grounds for failure of the valve to pass these tests, regardless of how satisfactorily the valve performed during the 5-h test. Impending failure or malfunction is defined as one which can be expected to occur within one year of operation.

S1.1.7 Shock Test—Sample size(s) for shock qualification testing shall be in accordance with MIL-STD-798. The valve shall be subjected to the high-impact mechanical requirements for Grade A, Class I of MIL-S-901 to determine its resistance to high-impact mechanical shock. The shock test shall be performed with the nominal hydrostatic pressure applied to the inlet port. During impact, an instantaneous, reversible pressure excursion is allowable.
S1.1.8 Vibration Test—The valve shall be vibration tested in accordance with Type I of MIL-STD-167-1.
S1.1.9 Maintenance Demonstration—The maintenance actions specified in 6.1.3 shall be demonstrated.
S1.1.10 Posttest Examination—After completion of the tests specified in 8.2-8.5 and S1.1.5 through S1.1.7, the test valve shall be disassembled and visually and dimensionally examined. Any damage, excessive wear, or signs of galling or pitting shall cause for rejection.

S2. Examinations
S2.1 Lot—All valves of the same type and size offered for delivery at one time shall be considered a lot for the purpose of sampling.
S2.2 Sampling for visual and dimensional examination. A random sample of valves shall be selected from each lot as shown below and shall be examined as specified in S2.3 and S2.4. Failure of any valve in a sample to pass the examination specified in S2.3 and S2.4 shall be cause for rejection of the lot.

S2.3 Visual Examination—A visual examination shall be made of the sample valves selected in accordance with S2.2 to verify conformance to the requirements of the specification.
S2.4 Dimensional Examination—A dimensional examination shall be made on the sample valves selected in accordance with S2.2 to verify conformance with the approved master drawing.

S3. Technical Data and Certification Requirements
S3.1 Drawings—Assembly drawings, information sheets, or catalog sheets of the pressure-reducing valve shall be provided to indicate the design and materials used in the valve.
S3.2 Technical Manuals—A technical manual or instruction booklet shall be supplied that provides a description of the valve, its operation and maintenance instructions, and illustrated parts breakdown. It shall also include wrench sizes and assembly torques (or equivalent) for all bolting and threaded assemblies, and step-by-step disassembly and reassembly procedures.
S3.3 Certification—Certification shall be provided indicating that the valve meets all requirements of the purchase order.

S4. Quality Assurance
S4.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.
S4.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.
S4.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.
S4.4 Review of quality assurance system. The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.
S4.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.
S4.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.
S4.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system that identifies inspection status of material throughout all stages of manufacture.
S4.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.
S4.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.
S4.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.
S4.11 Nondestructive Examination—Provisions shall be made to use nondestructive examination as necessary to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer and/or qualified by a recognized national body, and their authorizations/qualification records shall be made available to the inspection authority if required.
S4.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.
S4.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.
S4.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during all stages of manufacture and shall be able to distinguish between inspected and non-inspected material.

S4.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S4.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S4.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S4.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Specification for
Fabricated or Cast Automatic Self-Cleaning, Fuel Oil and
Lubricating Oil Strainers

This standard is issued under the fixed designation F 1567; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers automatic or continuously self-cleaning automatic strainers, or both, for use in fuel and lubrication oil systems. The strainer is designed to operate under positive pressure (discharge side of the pump). Strainers manufactured to this specification are suitable for use in any marine environment.

1.2 It is not the intent of this document to redefine existing filtration standards. The intent is to provide sound guidelines for purchasers and designers of lube oil and fuel oil systems. Nominal micron requirements and filter efficiencies shall be as agreed upon by the purchaser and manufacturer and stated in the purchase order document.

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 filter, or straining element—the replaceable component in a strainer that performs the barrier separation of solid particles from flowing fluid. It shall be removable for cleaning and servicing.

3.1.2 maximum allowable working pressure (MAWP)—the highest internal pressure that the strainer can be subjected to in service. The maximum non-shock working pressure for which a strainer is rated by the manufacturer on its nameplate.

3.1.3 maximum design temperature—the maximum temperature for which a strainer is rated by the manufacturer.

3.1.4 strainer—a device which, when installed in a pipeline, provides a mechanical means of removing suspended solids from flowing liquid.

3.1.5 Straining element open area. The net effective open area of the clean element through which the fluid can pass.

4. Classification

4.1 Strainers shall be furnished as Type I fuel oil or Type II lubricating oil. The strainers may be either hydraulic, electric, or pneumatic operated.

5. Ordering Information

5.1 Orders for strainers under this specification shall include the following:

5.1.1 This specification number,

5.1.2 Operating and design requirements for flow rate, pressure, temperature, nominal micron rating, fluid type, and viscosity. ASME Section VIII Division I Code Stamp requirements.

5.1.3 Flanged end connections class and type drilling, that is, ANSI, DIN, and so forth.

5.1.4 Orientation of inlet and outlet connections (see 6.2.9).

5.1.5 Repair spare parts package (see 14.1).

5.1.6 Quality criteria and test plan requirements.

5.1.7 Additional test or supplementary requirements (that is, ship motions and attitude constraints, see 7.3 and S1).

5.1.8 Strainer element open area if greater than requirements in 6.2.6.

5.1.9 Any special seal requirements.

5.1.10 Any special control requirements, that is, differential pressure gages, valves, control panels, motors and so forth.

5.1.11 Certified drawing requirements showing maintenance envelope and mounting details.

6. Materials and Manufacture

6.1 The strainer shall be designed to remove contaminating or unwanted solid particles, or both, from fuel oil and lube oil. The self-cleaning action shall be automatic, and shall have the ability to backwash, when required, the filtered fluid through the filter element in segments such that the contaminating particles are flushed free of the filter element. The self-cleaning action of each unit shall be driven by a motor (electric, pneumatic, or hydraulic.)

6.2 Components—Each strainer assembly shall consist of a housing with a removable cover, inlet and outlet connections, filter/straining element(s), self-cleaning mechanism(s), controls, and a differential pressure gauge. The strainer unit shall have suitable supports. The cross-sectional flow area throughout the unit shall be equal to or greater than that of the piping to which the strainer is connected.

6.2.1 Housing—The strainer housing, cover, flanges, and other items which form the pressure boundary shall conform to the requirements of the ASME Boiler and Pressure Vessel Code: Section VIII, Division 1, Pressure Vessels. Cast grey iron pressure retaining components shall not be used. Units requiring ASME stamp shall have it specified in the purchase agreement. The dirty oil inlet shall be located at the lower part of the body and arranged to help prevent contamination of the clean outlet side of the strainer during disassembly.

6.2.2 Cover—The removable cover shall be secured to the housing by threaded fasteners. Removal of the cover shall provide access to all internal components and shall not require unbolting the inlet and outlet strainer piping connections. Cover lifting devices with integral supports or lifting eyes shall be required for covers weighing more than 30 lb.

6.2.2.1 Antispray feature—The strainer cover shall contain a device to deflect fluid spray downward in the event of gasket failure. The spray deflector shall remain in position at all times when the cover is connected to the housing.

6.2.3 Gasket—The gasket or o-ring shall be capable of providing a positive seal under service and test conditions. The gasket shall be installed between the cover and strainer housing. This gasket shall be in place during the hydrostatic pressure test.

6.2.4 Pipe and Flange Dimensions—The inlet and outlet flanges shall be sized and drilled to conform with ANSI B16.5, Class 150 or 300, or as specified in the ordering data (see 5.1.3 and ANSI B 16.42).

6.2.5 Element Support—The filter element support shall not permanently deform when the assembly of the filter element and element support is subjected to the strength of internals test (see 9.3.3). The element support shall be designed to facilitate easy removal of the filter element and element support as one assembly. The element support must satisfy the flow area requirements of 6.2.6.

6.2.6 Filter Element—The filter element may be furnished in any corrosion resistant material compatible with the fluid in service. The filter element shall be attached to the element support in such a manner that it can be easily removed and replaced from the element support. The straining element open area shall be at least two to four times larger than the area of the strainer discharge connection.

6.2.7 Motor—The self-cleaning action of each unit shall be operated by a motor included as a part of the strainer. This motor can be hydraulic, electric or pneumatic.

6.2.7.1 Hydraulic motor—A motor exhaust connection sized to meet the strainer hydraulic motor shall be provided. This motor exhaust connection shall also be suitable for venting air during the initial fill and pressurization.

6.2.7.2 Electric motor—Electric motors shall be fractional horsepower, TEFC, NEMA design B, with a continuous rated
1.15 service factor or equivalent. Voltage, phase and cycle rating shall be stated in the purchase document.

6.2.7.3 Pneumatic motor—Design type shall be agreed upon between the purchaser and manufacturer.

6.2.8 Backflush Structure—The backflush structure shall periodically or continuously clean all of the filter element by backflushing system fluid through the element. The structure shall clean the filter element in segments so as not to disrupt the system flow through the strainer at any time. All impurities separated shall be isolated from the filtered liquid and discharged. All shaft penetrations shall require seals suitable for oil service.

6.2.9 Connections—The inlet and outlet connections shall be flanged. The inlet and outlet shall be permanently marked and identified.

6.2.9.1 Drain connections shall be provided. These connections shall be furnished with caps or plugs.

6.2.9.2 The unit shall have a suitable means of removing sludge from the strainer when it is isolated from service or during normal operation.

6.2.10 Lifting Attachments—Each housing and the cover shall be provided with suitable sling attachment areas for lifting in a normal position. If lifting eyes are used, each eye shall have the capability to carry the total weight.

6.2.11 Mounting—Free standing strainers shall be mounted by feet attached to the housing. Each foot must be provided with a suitable hole to accommodate one hold-down bolt.

6.3 Welding—Welding for nonpressure-boundary components shall be in accordance with the AWS Structural Welding Code. Welding for pressure boundary components shall be in accordance with the ASME Boiler and Pressure Vessel Code.

6.4 Treatment and Painting—The exterior of the strainer shall be treated and painted in accordance with standard commercial practice.

6.5 Material—Ductile iron, bronze, carbon steel, and stainless steel materials used in the fabrication of the automatic self-cleaning strainer shall not affect nor be affected by petroleum products. Materials shall be in accordance with ASTM or ASME specifications. Dissimilar metal connections shall be designed to provide optimum corrosion protection.

6.6 Seals—Strainer seals shall be elastomers suitable for this service.

7. Operating Requirements

7.1 Pressure—The strainer shall be suitable for operation in the range of 0.21 to 1.03 MPa (30 to 150 psi).

7.2 Temperature—The strainer shall be suitable for operation between 15 to 120°C (60 to 250°F) unless otherwise specified in the ordering data (see 5.1.2).

7.3 Shipboard Performance—Strainers shall be capable of operating in accordance with all requirements of this specification when subjected to the purchase agreement specified ship motion and attitude constraints (see 5.1.7).

7.4 Self-Cleaning Rate—The pressure drop through the strainer assembly shall not exceed the manufacturer’s maximum rated pressure drop during operation. Specifically, the self-cleaning mechanism shall be capable of maintaining the pressure drop below this value when contaminated fluid is being pumped through the strainer at the design flow specified in 5.1.2.

8. Workmanship

8.1 Workmanship—The strainer and its components shall be free from blow holes, porosity, hard spots, shrinkage defects and cracks. All surfaces shall be smooth and clean (reference MSS SP55). Where dimensions and tolerances affect interchangeability, operation, or performance or any combination thereof, they shall be held.

8.2 Cleaning—The strainer shall be cleaned of all extraneous material and dried.

9. Tests

9.1 Each strainer will have standard hydrostatic tests performed in accordance with Specifications F 1199 or F 1200 whichever is applicable. When specified as part of the purchase agreement, a detailed test plan may be submitted for approval. The performance, prototype and operational tests listed herein, shall be performed to prove the design. All strainers produced under this specification will meet these minimum requirements. Proof of test qualification shall be provided when specified in the purchase agreement.

9.2 Test Extensions—When the following conditions are satisfied, extension of a product test of one size to qualify another size is permitted (see Table 1):

9.2.1 Similar geometry and design characteristics.

9.2.2 Similar or stronger material than the tested unit.

9.2.3 Same pressure rating.

9.2.4 Similar or stronger end connections.

9.2.5 Similar sealing configurations.

9.2.6 Same mode of operation and operator attachment.

9.3 Operational Tests:

9.3.1 Flow Capacity Test—The test shall be performed in general accordance with Practice F 795. The pressure drop at the rated flow shall not exceed 0.07 MPa (10 psi) with a fluid viscosity of 250 SSU.

9.3.2 Inclined Flow Capacity Test—The flow capacity test in 9.3.1 will be performed at a list and trim angle of 30°.

9.3.3 Strength of Internals Test:

The filter elements shall be proven to withstand a minimum pressure differential of ten times the rated clean pressure differential or ⅓ of the maximum allowable working pressure (MAWP) of the housing, whichever is greater. The increased differential pressure shall be held or maintained for 30 min. The strainer assembly will then be disassembled and inspected.

(| TABLE 1 Test Extensions |

*Above 250 mm (10 in.), test extensions methods shall be agreed upon between the purchaser and the manufacturer and should be specified in the purchase agreement.*
Any permanent deformation or signs of damage shall constitute failure of the test. When testing methods are not practical, calculations or finite element analysis methods may be used as objective evidence that the strength of internals meet the requirements. The acceptance of these methods is to be a matter of contract and will be specified in the purchase agreement.

9.4 Self-Cleaning and Filtration Efficiency Test—The test fluid shall be an SAE 40 weight lubricating oil. The liquids viscosity should be either 250 or 500 SSU. This shall be clearly stated on the test report. The test report contaminants shall be silica sand with a known granular size and distribution.

The solids loading during the test shall be increased in intervals until a maximum value of 300 PPM is reached. Test data shall be recorded for a minimum of ½ h at each PPM loading.

Practice F 795 shall be used as a guide to performance testing and the reporting of test results.

10. Inspection

10.1 Responsibility for Inspection—The contractor is responsible for the performance of all inspection requirements. Except as otherwise specified in the contract or purchase order, the contractor may use his own or any other facilities suitable for the performance of the inspection requirements.

10.1.1 Responsibility for Compliance—Items must meet the requirements of Sections 6, 7, and 8, and, if so ordered, those of the Supplementary Requirements (see 5.1.7). The inspections set forth in this specification shall become a part of the contractor’s inspection system or quality program. The absence of inspection requirements in the specification shall not relieve the contractor of the responsibility of assuring that products or supplies submitted for acceptance shall comply with requirements of the contract. Quality conformance sampling does not authorize submission of defective material, nor does it commit the purchaser to accept defective material.

10.1.2 Quality Conformance Inspection—Quality conformance inspection shall consist of the visual and dimensional inspections specified in 10.1.3. Quality conformance inspection shall be accomplished on 100% of the assemblies offered. Only those assemblies which pass all inspections shall be delivered to the purchaser.

10.1.3 Visual and Dimensional Inspection—The visual and dimensional inspection shall consist of the inspection listed in Table 2.

10.1.4 Design Data Inspection—The contractor shall provide the purchaser with documentation to show that the requirements of Table 2 have been satisfied. This documentation may include drawings, engineering analyses, or test data, or any combination thereof. The inspections listed in Table 3 shall be verified by engineering review of the documentation provided.

11. Product Marking

11.1 Consult MSS SP25.

11.2 Identification—Identification plates, if required in the contract, shall be provided and shall include the following information:

11.2.1 The nominal pipe size of the inlet and outlet connections.
11.2.2 Design pressure, flow capacity.
11.2.3 The necessary operating instructions.
11.2.4 Weight when wet (operational weight).

12. Packaging

12.1 Protection—Strainer assemblies and their associated parts shall be individually preserved and packaged to afford adequate protection against corrosion, deterioration and physical damage from shipment between the supply source and the first receiving activity.

13. Supporting Documentation

13.1 Technical and Logistics Documentation—The contractor shall furnish the following publications applicable to the assemblies supplied under this specification:

13.1.1 Spare parts listing.
13.1.2 Maintenance, service, and repair manual.
13.1.3 Graph of expected pressure drop across the strainer assembly as a function of flow at various fluid viscosities. The maximum pressure drop allowed shall be indicated.
13.2 Test Report—Upon completion of the tests, a test report shall be prepared. The report shall be certified and signed by the contractor’s quality control representative.

14. Repair Parts

14.1 Repairs Parts Kit—When specified (see 5.1.5) a repair/spare parts kit shall be furnished and delivered with each assembly. The kit shall contain the parts and quantities specified in the contract.

15. Keywords

15.1 automatic self-cleaning strainers; fuel oil strainers; lubrication oil strainers; simplex strainers

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements apply only when specified by the purchaser in an order (see 5.1.7).

S1. Referenced Documents

S1.1 Government Specifications, Standards, and Handbooks—The following documents, of the issue in effect on the date of invitation for bids, form a part of this specification to the extent specified herein.

S2. Preparation for Delivery

S2.1 Preservation—Preservation shall be Level A or industrial, as specified.
S2.1.2 Level A—Cleaning, drying and preservatives shall be in accordance with MIL-P-116. Strainer unit shall be protected by Method I of MIL-P-116.
S2.1.2.1 Strainer assembly—All internal bare metal surfaces subject to corrosion shall be preserved using a preservative compatible to the system requirements. Unless otherwise specified. See S2.1, Type P2 of MIL-P-116 shall apply.
S2.1.2.2 External bare metal surfaces—Machined surfaces and unpainted corrodbile metal surfaces shall be coated with MIL-P-116 P-2 preservative and wrapped with greaseproof barrier material conforming to Type I, Grade A of MIL-B-121.
S2.1.2.3 Preservative protection—All equipment surfaces which are preserved shall be protected from direct contact with any blocking, dunnage, and shrouding by inserting one or more layers of barrier material conforming to Type I, Grade A of MIL-B-121 at points of contact.
S2.1.2.4 Openings—The open ends of all flanges and fittings shall be coated with MIL-P-116 Type P-2 preservative and sealed with similarly preserved blind flanges or plastic plugs/caps. The ends of the flanges and fittings shall be wrapped with greaseproof barrier material conforming to Type I, Grade A of MIL-B-121.
S2.1.2.5 Technical Publications—Technical publications, which accompany shipment prepared for Level A, shall be preserved in accordance with Submethod 1C-1 or MIL-P-116 and secured to the hardware package. Technical publications shall not be placed within the sealed barrier material used to enclose the strainer assembly. Technical publications, when shipped in bulk quantities shall be preserved to MIL-P-116 Submethod 1C-1 and packed in fiberboard containers in accordance with PPP-F-320.
S2.2 Packing—Strainers preserved as specified (see S3.1), shall be packed in exterior shipping containers for the level of packing specified in accordance with Table VII, exterior shipping container requirements, of MIL-STD-2073-1, and herein.
S2.3 Caseliners, Closure, and Gross Weight:
S2.3.1 Caseliners—Unless otherwise specified, shipping containers containing strainers preserved commercial shall be provided with waterproof caseliners in accordance with MIL-STD-2073-1.
S2.3.2 Closure—Container closure, reinforcing, or banding shall be in accordance with the applicable container specification or appendix thereto except that class-weather-resistant/fire-retardant fiberboard boxes shall be closed in accordance with Method V and reinforced with nonmetallic or tape banding and class-domestic/fire-retardant fiberboard boxes shall be closed in accordance with Method I using pressure-sensitive tape.
S2.3.3 Weight—Wood, plywood, and cleated type containers exceeding 200-lb gross weight (91-kg gross mass) shall be modified by the addition of skids in accordance with MIL-STD-2073-1 and the applicable container specification or appendix thereto.

S2.4 Industrial—Items prepared for shipment shall be packaged in accordance with Practice D 3951 (see 12.1).

S2.4.1 Container Modification—Shipping containers exceeding 200-lb gross weight shall be provided with a minimum of two 3- by 4-in. nominal (75- by 100-mm) wood skids laid flat, or skid- or all-type base which will support the material and facilitate handling by mechanical handling equipment during shipment, stowage, and storage.

S2.5 Marking—In addition to any special marking required, interior (unit and intermediate) packs and shipping containers shall be marked including bar coding and structural for shipment, stowage, and storage in accordance with MIL-STD-2073-1.

S3. Data Requirements

S3.1 Data Requirements—When this specification is used in acquisition and data are required to be delivered, the data requirements identified below shall be developed as specified by an approved Data Item Description (DD Form 1664) and delivered in accordance with approved Contract Data Requirements List (CDRL), incorporated into the contract. When the provision of DOD FAR Supplement, Part 27, Sub-Part 27.471-1 (DD Form 1423) are invoked and the DD Form 1423 is not used, the data specified below shall be delivered by the contractor in accordance with the contract or purchase order requirements. Deliverable data required by this specification are cited in the following paragraphs.

S3.1.1 Data item descriptions related to this specification, and identified in 5 and the Supplement will be approved and listed as such in DOD 5010.12-L, AMSDL. Copies of data item description required by contractors in connection with specific acquisition functions should be obtained from the Naval Publications and Forms Center or as directed by the contracting officer.

S3.2 Data Requirements Waiver Instructions—The data requirements of this specification may be waived by the contracting/acquisition activity upon certification by the officer that identical data were submitted by the officer and accepted by the Government under a previous contract for an identical item acquired to this specification. This does not apply to specific data which may be required for each contract regardless of whether an identical item has been supplied previously (for example, test reports). When specified in the contract or order, a certificate of compliance shall be prepared.

S3.3 Technical Manuals—The requirement for technical manuals and technical repair standards should be considered when this specification is applied to a contract. If technical manuals are required, military specifications and standards which have been cleared and listed in DOD 5010.12-L (AMSDL) must be listed on a separate CDRL (DD Form 1423), included as an exhibit to the contract. The technical manuals must be acquired under separate contract line item in the contract.

S3.4 Drawings—Drawings shall be prepared in accordance with S3.1. One set of reproducible (or microfilm) drawings shall be furnished to the contracting agency after first article inspection approval.

S3.5 Identification—Identification plates shall be provided in accordance with MIL-P-15024 and MIL-P-15024/5, and shall include the following information:

S3.5.1 The nominal pipe size of the inlet and outlet connections.
S3.5.2 Design pressure, flow capacity.
S3.5.3 The necessary operating instructions.
S3.5.4 National Stock Number (NSN).
S3.5.5 Weight when wet (operating weight).
S3.6 Technical, Logistics Documentation—The contractor shall furnish the following publications applicable to the assemblies supplied under this specification:

S3.6.1 Spare parts listing.
S3.6.2 Maintenance, service, and repair manual.
S3.6.3 Graph of expected pressure drop across the strainer assembly as a function of flow at various fluid viscosities. The maximum pressure drop allowed shall be indicated.

S4. Inspection

S4.1 Classification of Inspections—The inspection requirements specified herein are classified as follows:

S4.1.1 First article inspection (see S4.2).
S4.1.2 Quality conformance inspection (see 10.1.2).

S4.2 First Article Inspection—First article inspection shall consist of the visual and dimensional inspections and the design data inspections specified in Section 10, and the tests specified in 9.1, in that order. The strainer assembly must pass all inspections and tests specified to be considered acceptable.

S4.3 First Article—The contractor shall furnish a sample strainer for first article inspection and test (see S4.5).

S4.4 Inspection System—An inspection system program plan shall be prepared (see S4.1).

S4.5 First Article—When a first article inspection is required, the items shall be a first article sample. The first article shall consist of the units specified. The contracting officer should include specific instructions in acquisition documents regarding arrangements for examinations, approval of first article test results and disposition of first articles.

S4.5.1 Invitations for bids should provide that the Government reserves the right to waive the requirement for samples for first article inspection to those bidders offering a product which has been previously acquired and tested by the Government, and that bidders offering such products, who wish to rely on such production or test, must furnish evidence with the bid that prior government approval is presently appropriate for the pending contract.

S4.6 Reliability—The contractor shall provide, with the first article, an engineering calculation of the mean time between failure for the strainer operating under the conditions specified herein.
S5. Shock, Vibration, and Acoustic Requirements

S5.1 Mechanical Shock—The strainer assembly, including the differential pressure gauges, shall meet the high impact shock requirements of MIL-S-901 for Grade A, Class 1 equipment.

S5.1.1 Mechanical Shock Test—This test shall be conducted in accordance with MIL-S-901. All functions of the strainer assembly shall be unaffected by this test. Any unit not meeting MIL-S-901 shall be rejected.

S5.2 Vibration—The self-cleaning simplex strainers shall be designed and tested to function satisfactorily under the requirements of MIL-STD-167-1 Type 1 environmental vibration.

S5.2.1 Vibration Test—This test shall be conducted in accordance with MIL-STD-167-1. All functions of the strainer assembly shall be unaffected by this test. Any unit not meeting MIL-STD-167-1 shall be rejected.

S5.3 Acoustic Requirement—When operating, the strainer assembly shall conform to the airborne noise requirements of MIL-STD-740 for Grade C equipment.

S5.3.1 Acoustic Requirement Test—This test shall be conducted in accordance with MIL-STD-740. The sound energy limits imposed by MIL-STD-740 for Grade C equipment shall not be exceeded.

S5.4 Tests—Table S5.1 lists required tests; a test plan shall be submitted for approval before testing.

S6. Other Requirements

S6.1 Subcontracted Material and Parts—The packaging requirements of referenced documents listed in Section S1 do not apply when material and parts are acquired by the contractor for incorporation into the equipment and lose their separate identity when the equipment is shipped.

S6.2 Repair Parts—A repair parts kit shall be furnished and delivered with each assembly. The kit shall contain the parts and quantities specified in the contract.

S6.3 Depreservation Instructions—A set of instructions covering the depreservation of the equipment shall be furnished. Instructions shall show all information necessary for depreservation, such as, but not limited to: the addition of lubricants prior to operation, flushing of lines, removal of greaseproof barrier and the location of detached components. Instructions shall be packaged in a transparent waterproof plastic bag, minimum 4 mil (100 µm) thick. Closure shall be by heat sealing. The shipping container in which the instructions are packed shall be marked to so indicate.
Standard Practice for Preparing Shipboard Fire Control Plans

INTRODUCTION

Title 46 of the Code of Federal Regulations 35.10-3, 78.45-1, and 97.36-1 contain the requirements for fire control plans aboard Coast Guard inspected vessels. When required, foreign and U.S. vessels on international voyages must comply with the 1974 International Convention for the Safety of Life at Sea (SOLAS). Contained in Regulation II-2/20 and 41-2 of the 1974 SOLAS Convention are requirements for shipboard fire control plans. This practice provides guidance on the symbols to be used in shipboard fire control plans, and has been developed in general conformance with the International Maritime Organization’s Assembly Resolution A.654(16).

1. Scope

1.1 This practice sets forth the symbols to be used in shipboard fire control plans.

2. Referenced Documents

2.1 ASTM Adjuncts:
   F 1626 Shipboard Fire Control Plan

3. Significance and Use

3.1 The fire control plan is a set of general arrangement plans for each deck of the ship that contains information that will be of use to the ship’s crew and shoreside firefighters in the event of a fire. Experience has shown that in casualties involving fire, one of the most valuable assets on the ship is the fire control plan. Most of the information the ship’s crew and shoreside fire fighting personnel would need, such as general layout and dimensions, fire fighting systems, and other systems that have a direct impact on fire fighting, are included in the fire control plan. The fire control plan is also ideal for firefighters and marine inspectors to use as a guide when taking tours on ships, since it contains the location of most items they will be looking for. In addition, having a consistent set of standard fire control plan symbols will eliminate the need for shoreside fire fighting personnel to know each ship’s respective fire control plan symbols.

4. General Requirements

4.1 The fire control plan symbols should be displayed on a general arrangement-type plan. The general arrangement-type plan should show all spaces on each deck, and the symbols used should identify the information needed for use by shipboard or shore-based firefighters. The information required to be displayed on fire control plans should be in accordance with the 1974 SOLAS Convention, Regulation II-2/20, 41-2 or as determined by the vessel’s flag administration, or both.

5. Physical Requirements

5.1 Dimension—Shall be as required by scale.

5.2 Scale—The scale used on fire control plans shall allow for clear and legible representation of all symbols and lettering.

5.3 Color—Finish shall allow for good contrast and representation of the color symbols.

6. Symbols

6.1 A legend identifying all symbols and supplementary symbols or figures shall be provided.

6.2 Scale of the symbol shall be the same size in relation to all others.

6.3 The effectiveness of these symbols may be enhanced by the use of supplementary indicators. If such indicators are used, they may be placed inside of, or adjacent to, the symbol as seen fit.

7. Illustration of Symbols

7.1 The symbols are available separately in an adjunct.

8. Keywords

8.1 fire control plans; fire fighting; marine technology; shipboard fire; ships
Standard Specification for
Insulation Monitors for Shipboard Electrical Systems
[Metric]¹

1. Scope

1.1 This specification covers two (2) types of electrical system insulation monitoring devices.

1.1.1 Type I is an ac device intended as a permanently installed unit for use in the detection of ohmic insulation faults to ground in active ac ungrounded electrical systems up to 1000 VAC, having dc components up to 1500 VDC.

1.1.2 Type II is a dc device intended as a permanently installed unit for use in the detection of ohmic insulation faults to ground in dc ungrounded electrical systems up to 1500 VDC.

1.2 Limitations—This specification does not cover devices that are intended for operation in ac ungrounded systems without dc components.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The following precautionary caveat pertains only to the test methods portion, Section 7 of this specification: This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 UL Standard:
UL STD 840 Insulation Coordination Including Clearances and Creepage Distances for Electrical Equipment²

2.2 IEC Standards:
IEC 255-5 Insulation Tests for Electrical Relays³
IEC 364-4-41 Electrical Installations of Buildings/

Protection for Safety/Protection Against Electrical Shock³

2.3 Military Standard:
MIL-STD-1399 (NAVY) Section 300A Interface Standards for Shipboard Systems; Electrical Power, Alternating Current⁴

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 ac or dc ungrounded electrical system, n—a system that has no intentional connection to ground and can continue to perform normally if one conductor becomes connected to ground.

3.1.2 measuring signal, n—the output signal from the insulation monitor that is superimposed between the ac or dc ungrounded system to be monitored and ground.

3.1.3 response value, n—the adjustable or preset set-point value of the system insulation resistance at which an insulation monitor will provide an alarm indication.

3.1.4 system leakage capacitance, n—the total capacitance to ground of the system including all connected consumers.

3.1.5 touch voltage, n—the voltage appearing during an insulation fault, between simultaneously accessible parts. This term is used only in connection with protection against indirect human contacts, that is, no direct human contact with a live conductor. The International Electrotechnical Commission (IEC) limits the maximum prospective touch voltage which can be maintained indefinitely to 50 VAC rms or 120 V ripple-free dc.

4. Ordering Information

4.1 Orders for monitoring devices under this specification shall state the following information:

4.1.1 Type and quantity.

4.1.2 Nominal system voltage and frequency (for ac system).

4.1.3 Input supply voltage.

4.1.4 Response value/set-point range expressed in K-Ohms.

¹ This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.10 in Electrical.
² Available from Underwriters Laboratories, Inc., 333 Pfingsten Rd., Northbrook, IL 60062.
³ Available from American National Standards Institute (ANSI), 25 W. 43rd St., 4th Floor, New York, NY 10036.
⁴ Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5098, Attn: NPODS.
4.1.5 ASTM designation and year of issue.
4.1.6 System leakage capacitance or data from which an estimate of its magnitude can be determined.
4.1.7 Special requirements such as Test/Reset buttons, ohmmeters, visual indicators, memory fault retention, and so forth.

5. Materials and Manufacturing Methods
5.1 The materials and manufacturing methods used shall be such that the resulting products will conform to the properties and characteristics prescribed in this specification.

6. Performance Requirements
6.1 Response of Insulation Monitor to a Step Input—The insulation monitor measures the combined parallel resistance to ground from all power or circuit conductors. The time to respond to a step change in the actual resistance to a value less than or equal to 50% of the desired response value shall be governed by the expression:

\[ t(s) \leq 100 + 40(R_i \times C_s) \]  

where
\[ R_i = \text{internal resistance of monitor, ohm, and} \]
\[ C_s = \text{total system capacitance, farad.} \]

For example,
\[ t = 124 \text{ s if } R_i = 120,000 \text{ ohm and } C_s = 5 \times 10^{-6} \text{ farad.} \]

6.2 Measuring Signal Voltage Limits—The peak value of the measuring signal shall be limited to a magnitude deemed acceptable by applicable safety standards for the intended use. The peak value of the measuring signal shall be less than the touch voltage limits: 120 VDC ripple-free and 50 VAC rms.

6.3 Internal Impedance and Internal Resistance—The internal impedance and dc internal resistance shall be at least 30 ohms per volt nominal system voltage but in either case shall not be less than 12 K-Ohms.

6.4 Response Tolerance—The response tolerance of the monitor shall not exceed 0 to +50% of the upper value of the set point range when measured at a room temperature of 25 ± 5°C (72 ± 9°F), with an input supply voltage 80–115% of its nominal value and with a system leakage capacitance equal to the value at which the monitor is calibrated (1 µfd minimum).

6.5 Working Range of System Voltage and Frequency—The insulation monitor shall perform as specified when operating with a system voltage of 0–115% nominal over the frequency range 50–400 Hz.

6.6 Self-Test—The insulation monitor shall include a built-in test device or be equipped with connection provisions for a separate device that shall be furnished with the equipment which can verify the proper functioning for the monitor.

6.7 Output Relay—The insulation monitor shall have provisions for an external (remote) audible or visual alarm to operate when the insulation resistance value falls below the set-point value or a remote indication of the insulation resistance value of the ungrounded system, or both. Built-in relays contacts for connection to an external alarm shall have a continuous rating of at least 4 amperes at 250 VAC. The break capacity shall be at least 2 amps at 250 VAC (0.7 power factor) and 0.3 amps at 120 VDC.

6.8 Built-In Display of Insulation Resistance—If provisions are made to indicate (display) the current insulation resistance level, then the manufacturer shall provide information as to the accuracy of this indication during normal operating conditions.

6.9 Clearance and Creepage Distances—The insulation monitor shall have protective spacings through air (clearance) and over surface (creepage) as stated in UL STD 840 for the intended maximum circuit voltage.

6.10 Impulse Voltage Withstand Tests—The insulation monitor shall meet the IEC 255-5 Class III Impulse Voltage Withstand Test Requirements.

7. Operating Environment
7.1 The insulation monitor shall reliably function over an ambient temperature range of 0 to 50°C (32 to 122°F) and at a relative humidity of 95%. Storage temperatures of −20 to +60°C (−4 to 140°F) shall not damage the insulation monitor.

8. Test Methods
8.1 Conformance Test—Conformance testing of insulation monitors shall be performed to confirm that the response tolerances stipulated are not exceeded and that the requirements of Section 6 are met.

8.1.1.1 An insulation monitor with adjustable response shall be tested at the beginning, mid and end points of its range. These tests shall be done without connected capacitances. The test resistor must be decreased slowly to ensure that a static response value is read. If the measuring principle is dependent on the system leakage capacitance, the tolerances must be tested in accordance with 6.4. This test is done by increasing the test capacitance step by step to the value at which the monitor was calibrated.

8.1.2 Testing of Response Time—At a system leakage of 1 µfd, there shall be a step change in the insulation level from nearly infinity to 50% of the derived response value. The time for the output relay to react shall be measured.

8.1.3 Testing of Peak Voltage—Peak voltage measurements are taken to confirm that the requirements for 6.2 are met. The voltmeter’s internal resistance should have a minimum value not less than 20 times the dc internal resistance of the measuring circuit.

8.1.4.1 Testing the ac Internal Impedance—The ac internal impedance specified in 6.3 is verified without any input supply voltage, with an rms milliammeter and with an external power supply wired between the linked measuring terminals and the...
ground terminal. The power supply must have an ac output rated at nominal voltage, nominal frequency, a harmonic distortion of less than 5% and internal impedance of under 10 ohms. The monitor’s internal impedance is calculated as follows:

\[ Z_r = \frac{\text{Nominal System Voltage}}{\text{ac rms Current}} \]  \hspace{1cm} (2)

8.1.4.2 Testing the dc Internal Resistance—The external power supply must have a dc output rated at nominal system voltage. The monitor’s internal resistance is calculated as follows:

\[ R_r = \frac{\text{Nominal System Voltage}}{\text{dc Current}} \]  \hspace{1cm} (3)

8.1.5 Testing of Built-in Meters—If indication instruments are built into the insulation monitor, they must be checked so that they comply with the response tolerances laid down in 6.8.

8.1.6 Testing the Impulse Voltage Withstand Capabilities—These tests will follow the procedure outlined in IEC 255-5 Class III.

8.2 Routine Tests—Each monitor must undergo a test during production to prove that the insulation monitor functions correctly.

8.2.1 Testing of Response Value—Routine tests should be performed at room temperature 25 ± 5°C (72 ± 9°F) with rated input supply voltage. The insulation monitor must comply with the requirements of 6.4.

8.2.1.1 The response of the insulation monitor is to be tested at the beginning and end points of the range if it has a steplessly adjustable response value.

8.2.2 Testing of Self-Test Function—The internal and external test buttons must be checked according to 6.6. The built-in test device’s proper functioning must be verified.

8.2.3 Testing of Built-in Meters—If the insulation monitor has built-in indication meters, they must be checked so that they comply with the response tolerances according to 6.8. The test should be performed at room temperature with rated input supply voltage.

8.2.4 Voltage Test—A voltage test is performed on the monitor to verify that the monitor is able to withstand an ac test voltage equal to twice the nominal systems voltage plus 1000 V for a period of one second without breakdown or flashover. The test voltages shall be applied directly to the terminals. Unless obvious, the independent circuits are those which are so described by the manufacturer.

8.2.4.1 Link all terminals of each independent circuit. Note that circuits having the same rated insulation voltage may be connected together when conducting the test in accordance with 8.2.4.3.c.

8.2.4.2 Link all terminals of open-contact² circuits.

8.2.4.3 Apply test potential: (a) between linked independent circuits; (b) between linked-independent circuits and linked open-contact circuits; (c) between linked independent circuits and exposed conductive parts.

8.2.5 Verification of Markings, Labels and Manuals—Visual examination should verify appropriate markings as specified in Section 9.

9.1 The following data shall be included on all enclosures for insulation monitors:

9.1.1 Name of manufacturer.
9.1.2 Type of monitor.
9.1.3 Connection diagram.
9.1.4 Input supply voltage.
9.1.5 Nominal supply voltage and frequency (for ac systems).
9.1.6 Response value or response range.
9.1.7 Test resistance value.
9.1.8 Serial number or year of production.
9.2 Manufacturer’s equipment manual shall provide the following information in addition to the above requirement.
9.2.1 Description of operation.
9.2.2 ac internal impedance or dc internal resistance.
9.2.3 Connection diagram.
9.2.4 Nominal value of measuring signal.
9.2.5 Maximum measurement current.
9.2.6 Nominal contact voltage and current ratings for integral relays per 6.7.
9.2.7 A note advising that system leakage capacitance may influence the measurement.
9.2.8 A note advising that only one monitor may be connected per galvanic circuit and that one monitor must be disconnected when two ungrounded systems containing independent monitors are coupled together.

1. Scope

1.1 This specification covers the design, construction, testing and operating requirements for pressure-reducing manifolds for air or nitrogen systems, referred to herein also as manifolds. The term manifold constitutes the combination of all components and piping between, and including, the inlet and outlet ports (see Fig. 1 and Fig. 2).

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses (metric SI units) are for information only.

3. Terminology

3.1 Definitions:
3.1.1 accuracy of regulation—the amount by which the downstream pressure may vary when the manifold is set at any pressure within the required set pressure range and is subjected to any combination of inlet pressure, flow demand, and ambient temperature variations within the specified limits.
3.1.2 bubble-tight—No visible leakage over a 5-min period using either water submersion or the application of bubble fluid for detection.
3.1.3 external leakage—Leakage from the manifold which escapes to atmosphere.
3.1.4 flow rate demand—the amount of flow demanded at any given time by the system downstream of the manifold.
3.1.5 flow rate demand range—the range over which the flow demand can vary.
3.1.6 hydrostatic shell test pressures—the hydrostatic test pressures that the inlet and outlet sections of the manifold are required to withstand without damage. Manifold operation is not required during application of shell test pressure, but the manifold must meet all performance requirements after the shell test pressure has been removed.
3.1.7 inlet operating pressure range—the range over which the inlet pressure supplied to the manifold can vary under any operational conditions which the manifold can be subjected to in service.
3.1.8 internal leakage—leakage from higher pressure to lower pressure portions of the manifold and which does not escape to atmosphere.
3.1.9 manifold rated pressures—the inlet and outlet pressure ratings of the manifold. These rated pressures are selected from the applicable pressure ratings (see 4.2) and specified in the ordering information (see Section 5). The inlet pressure rating is applicable from the manifold inlet up to and including the seats of the outlet stop valve and bypass throttle valve. The
outlet pressure rating is applicable from the outlet side of the seats of the outlet stop valve to the manifold outlet and the bypass throttle valve to the manifold outlet.

3.1.10 manual valves—these are all the manually operated valves in the manifold which include handwheel-operated valves and wrench-operated valves. The handwheel-operated valves are the inlet and outlet stop valves, and the bypass throttle valve. The wrench-operated valves are the upstream and downstream bleed valves and the gage isolation valve. The requirements for any manually operated valves installed in the pressure-reducing valve are covered under 6.5.1.

3.1.11 maximum flow rate demand—the maximum amount of flow demanded of the manifold by the downstream system.

3.1.12 maximum inlet operating pressure—the highest pressure supplied to the inlet of the manifold in service.

3.1.13 maximum outlet operating pressure—the highest pressure at the manifold outlet in service. This is established by the accuracy of regulation of the pressure-reducing valve.

3.1.14 maximum set pressure—the highest set pressure at which the manifold can meet the performance requirements specified.

3.1.15 minimum flow rate demand—the minimum flow rate demanded of the manifold by the downstream system.

3.1.16 minimum inlet operating pressure—the lowest pressure supplied to the inlet of the manifold in service.

3.1.17 minimum outlet operating pressure—the lowest pressure at the manifold outlet in service. This is established by the accuracy of regulation of the pressure-reducing valve.

3.1.18 minimum set pressure—the lowest set pressure at which the manifold can meet the performance requirements specified.

3.1.19 operating pressures—the pressures within the manifold during service.

3.1.20 pressure-reducing valve—the component of the manifold which accomplishes automatic regulation of the downstream pressure. In this component, the upstream pressure is reduced to the desired downstream pressure.

3.1.21 pressure-relief valve—the component of the manifold which protects the manifold and downstream systems against downstream over pressurization.

3.1.22 set pressure—the outlet pressure delivered by the manifold at the time the pressure setting is made. For the
purposes of this specification, it will be assumed that the setting is made when there is no flow demand on the manifold ("lock-up" condition), and the manifold is at surrounding ambient temperature.

3.1.23 set pressure range—the range of set pressures over which the manifold can be adjusted while meeting the performance requirements specified.

3.1.24 wide open capacity—the flow rate when a valve is in a position which presents the least resistance to flow.

4. Classification

4.1 Configuration—Manifolds shall be of the following configurations and specified in the ordering information (see 5.1).

   Configuration 1-1 One reducer, one relief (see Fig. 1).
   Configuration 2-1 Two reducers, one relief (see Fig. 2).

4.2 Pressure Ratings—Manifolds shall have inlet-rated pressures and outlet-rated pressures selected from the following categories: 400-, 1500-, 3000-, and 6000-psig (2.8-, 10.3-, 20.7-, and 41.4-MPa gage pressure). The inlet and outlet pressure ratings selected shall be specified in Section 5.

4.3 End Connections—Manifolds shall have inlet and outlet end connections selected from those listed in Table 1 and specified in Section 5.

5. Ordering Information

5.1 Ordering documentation for manifolds under this specification shall include the following information, as required, to describe the equipment adequately:

   5.1.1 ASTM designation and year of issue,
   5.1.2 Size and type of inlet end connection (see 4.3 and 6.4.2),
   5.1.3 Size and type of outlet end connection (see 4.3 and 6.4.2),
   5.1.4 Size and type of end connections for pressure-reducing valve and pressure-relief valve,
   5.1.5 If tail pieces and union nuts are required (when required, their material of construction shall be per Table 1),
   5.1.6 Manifold configuration, inlet and outlet pressure ratings (see 4.1 and 4.2),
   5.1.7 Manifold inlet operating pressure range,
   5.1.8 Type of mounting required: bottom or back mounting (see 6.4.3),
   5.1.9 Set pressure and set pressure range, if other than specified (see 7.3),
   5.1.10 Flow rate demand range (see 7.1, S1.1.6),
   5.1.11 Accuracy of regulation required, if other than specified, or if set pressure is below 10 psig (see 7.2),
   5.1.12 Relief valve set pressure and accumulation pressure (if different from Specification F 1508),
   5.1.13 Ambient atmospheric conditions: temperature range, chemical contaminants, if any,
   5.1.14 Quality of inlet air/nitrogen gas: temperature range, moisture content, oil/lubricant contaminants, if any,
   5.1.15 Special tools required (see 6.7),
   5.1.16 Tamper-proof lead seal if required (see Specification F 1795, Section 5),
   5.1.17 Supplementary requirements, if any (S1 through S4), and
   5.1.18 Maximum vibration frequency, if other than specified (see S1.1.9).

6. Manifold Construction

6.1 Manifolds shall incorporate the design features specified in 6.2-6.11.

6.2 Materials of Construction—Material requirements for the assemblies in the manifold shall be as specified in the applicable component specifications referenced herein. Materials for all other parts, including the inlet and outlet manifold blocks, shall be 300 series corrosion-resistant steel (SS304, 304L, 316, or 316L) or other materials selected to provide weldability and corrosion resistance without requiring painting, coating, or plating. The inlet and outlet manifold blocks shall be weld repairable. Materials for contacting parts shall be selected to minimize electrolytic corrosion and galling. Metallic materials shall conform to applicable ASTM specifications. Nonmetallic materials shall be compatible with the line medium.

6.3 General Requirements—Manifolds shall incorporate the functional elements shown schematically in Fig. 1 or Fig. 2, as applicable, and delineated below:

   (a) Inlet and outlet stop valves,
   (b) Upstream and downstream bleed valves (for depressurization of all components and fluid cavities),
   (c) Pressure-reducing valve(s),
   (d) Pressure-relief valve,
   (e) Gauge isolation valve, and
   (f) Bypass throttle valve.

All components shall be part of a manifold assembly, as shown in Fig. 3 or Fig. 4, as applicable, which requires only one inlet and one outlet connection to the main flow path of the piping system in which it is installed. The inlet and outlet connections shall be in-line. The manifold shall be fabricated from inlet and outlet blocks, with interconnecting piping for the pressure-reducing valve(s) and bypass throttle valve flow paths. The manual valves shall be cartridge mounted into the inlet and outlet manifold blocks as shown in Fig. 3 or Fig. 4, as applicable. The pressure-reducing valve and the pressure-relief valve shall be mounted by way of takedown connections in accordance with Table 1. The manifold shall be capable of meeting all requirements of this specification and provide extended reliable operation when protected by a 5-µm nominal/
18-µm absolute filter installed upstream of the manifold inlet and when subjected to conditions specified in Section 5.

6.4 Design Construction Requirements

6.4.1 Pressure Envelope—The hydrostatic shell test pressures shall be 1.5 times the manifold rated inlet and outlet pressures.

6.4.2 Connections—The main-line inlet and outlet connections of the manifold, the inlet and outlet connections of the pressure-reducing valve(s), the connections for the bypass line, and the inlet and outlet connection to the pressure-relief valve shall be takedown joints (unions or other as specified) as specified in Table 1 based on rated pressures specified. Any exposed threads shall be protected by plastic caps for shipping. The main-line inlet and outlet connection of the manifold and the inlet and outlet connection for the pressure-reducing valve(s) shall permit axial adjustment to expedite proper installation of the manifold into the piping system and to facilitate replacement of the pressure-reducing valve(s) with one of another make or model or which is for some other reason not dimensionally identical to the originally installed pressure-reducing valve(s). The axial adjustment feature for the pressure-reducing valve(s) shall be included in that portion of the takedown joints that are connected to the inlet and outlet manifold blocks. If unions per Table 1 are specified for the pressure-reducing valve(s) inlet and outlet connections, the thread pieces shall be the portions of the unions that are attached to the pressure-reducing valve(s). The range over which each of the four adjustable connections noted above can be adjusted shall be as specified in Table 2. A positive and permanent means shall be incorporated to ensure that none of the four adjustable connections can be backed out beyond their minimum engagement position. The size of the main-line inlet and outlet connections of the manifold shall be as specified (see Section 5).

6.4.3 Manifold Mounting—The manifold shall be given structural integrity by means of a subplate provided as part of the manifold. The subplate shall be an angle form to provide an accurate mounting surface for both back and bottom mounting and shall be bolted to the inlet and outlet manifold blocks in such a way as to not interfere with mounting the manifold to a foundation plate. The manifold shall be drilled and tapped or through-drilled to allow either bottom mounting or back mounting as specified (see Section 5). All components shall be fully and easily accessible for operation, service, or removal from the manifold.

6.4.4 Threads—Threads shall be as specified in ASME B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock wire shall not be used.

6.4.5 Interchangeability—The entire manifold, including components and all associated piece parts, shall have part number identity and shall be replaceable from stock or the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s part number shall be directly interchangeable with each other with respect to installation (physical) and performance (function). Physically interchangeable assemblies, components, and parts are those that are capable of being readily installed, removed, or replaced without alteration, misalignment, or damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.4.6 Nonmetallic Element Interchangeability—Nonmetallic elements, including but not limited to, seat rings, poppet seat inserts, cushions, and O-rings, shall be treated as separately identified and readily replaceable parts.
6.4.7 Pressure Gage—The manifold shall be provided with a ¼-in. (DN 8) threaded gage connection port to permit attachment of a pressure gage for sensing the outlet pressure. The gage connection under all operating conditions shall be located to measure accurately pressure at the manifold outlet connection when using either the pressure-reducing valve or the bypass throttle valve to control flow. A gage isolation valve shall be provided in the manifold.

6.4.8 Bleed Valves—Bleed valves as shown in Fig. 1 and Fig. 2 shall be provided to allow depressurization of piping and components.

6.5 Component Requirements:

6.5.1 Pressure-Reducing Valve—Pressure-reducing valve(s) incorporated in the manifold shall be in accordance with Specification F 1795, Type I construction. The pressure rating shall be in accordance with 4.2 and shall equal the manifold inlet pressure rating.

6.5.1.1 Pressure reversal—The manifold shall withstand, without damage, a condition in which the pressure-reducing valve is subjected to a maximum reverse pressure differential. This can occur where the maximum set pressure exists at the pressure-reducing valve outlet, the pressure-reducing valve loading element is deactivated (that is, if it is a spring-loaded, pressure-reducing valve, the set spring adjustment is backed off fully; and if a gas-dome loaded pressure-reducing valve, the dome charge is vented off completely), and inlet pressure is vented off.

6.5.2 Pressure-Relief Valve—The requirements and definitions for the pressure-relief valve incorporated in the manifold shall be as specified in Specification F 1508.

6.5.3 Manual Valves—The requirements for the manual valves incorporated in the manifold shall be as specified in 6.5.3.1-6.5.3.6.

6.5.3.1 Mounting—All manual valves shall be cartridge mounted into the manifold blocks.

6.5.3.2 Seats—Each manual valve shall incorporate a non-metallic seating feature for tight shutoff.

6.5.3.3 Handwheel operating force—For hand-operated valves, the maximum permissible total tangential force required on the rim of the handwheel for operating, or seating/unseating the valves shall not exceed 50 lbs (220 N) when the valve is subjected to the maximum operating pressure.

FIG. 4 Components of Manifold Assembly
6.5.3.4 Bidirectional shutoff—All manual valves shall be capable of operation and tight shutoff when pressure is applied in either direction.

6.5.3.5 Pressurization rate—All manual valves shall be capable of being operated to limit the rate of downstream pressure buildup in a depressurized volume (with maximum pressure upstream) to 200-psig (1379-KPa gage pressure) per second. Downstream volumes for this pressurization rate requirement shall be taken as the applicable manifold volumes. For design and test purposes, a stop valve not more than ten diameters downstream of the manifold outlet connection shall be assumed.

6.5.3.6 Bypass throttle valve—The bypass throttle valve shall be sized to pass full-rated flow of the manifold and control the outlet pressure at all flow demands and inlet pressures within the range of the manifold.

6.6 Manifold Envelope Dimensions—Manifold envelope dimensions shall be as specified in Fig. 3 or Fig. 4 and Table 3, as applicable.

6.7 Maintainability—The manifold shall permit direct access for disassembly, repair, and reassembly of all internal working parts and subassemblies when mounted for operation on its subplate and installed into the system. Maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified and shall be supplied when ordered (see Section 5).

6.8 Reversibility—Seating inserts shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.9 Adjustments—There shall be no adjustments required in the manifold during or after assembly other than the axial positioning of the takedown connections for installation of the pressure-reducing valve into the manifold or installation of the manifold into the system and the set points of the pressure-reducing valve and the pressure-relief valve.

6.10 Reliability—Periodic maintenance of the manifold or any of its components shall not be required. There shall be no postassembly lubrication required.

6.11 Ruggedness—To the maximum extent practical, the manifold and its components shall be designed to prevent damage, malfunction, or leakage as a result of foreign particle or other line media contamination or from mishandling.

7. Performance

7.1 Manifolds shall meet the performance requirements of 7.2-7.7.

7.2 Flow Capacity—The maximum and minimum flow rate demand required shall be specified (see Section 5) in standard cubic feet per minute at 60°F (15.6°C) and 14.7 psia (101 kPa absolute). The manifold shall meet the specified maximum and minimum flow rate demand requirements, or any intermediate flow rate demand requirement, and shall operate without hunting or chattering under all specified conditions.

7.3 Accuracy of Regulation—Manifold regulated pressure shall be maintained within the accuracy of regulation limits specified in Table 4 (unless different limits are specified in Section 5) under all flow rate demand and inlet pressure conditions specified.

7.4 Range of Set Pressure Adjustment (Set Pressure Limits)—Unless otherwise specified in Section 5, the set pressure range shall be as follows: Where the manifold uses a mechanical spring, the set pressure shall be adjustable through a range of at least 5% or 2 psi (14 kPa), whichever is greater, on either side of the specified set pressure. Where the manifold uses a gas spring (dome loading), the set point shall be adjustable through a range of at least 25% or 10 psi (69 kPa), whichever is greater, on either side of the specified set pressure.

7.5 Accumulation—The pressure-relief valve shall be sized to pass at the maximum inlet pressure the wide open capacity of the pressure-reducing valve, or the wide open capacity of the by-pass throttle valve, whichever is greater, and limit the downstream pressure to the accumulation pressure. The accumulation (overpressure) limits shall be per Specification F 1508.

7.6 **Seat Tightness**—Handwheel-operated valves shall be bubble-tight in both directions when closed with a force not exceeding that specified in 6.5.3.3 (or the manufacturers’ recommendations, when less). The pressure-reducing valve shall meet the seat tightness requirements of 8.5. Where necessary, leakage measurement shall start after temperature stabilization.

7.7 **External Leakage**—Manifold external leakage shall be bubble-tight at operating pressure conditions over a 5-min period.

8. **Tests Required**

8.1 Each manifold shall pass the tests outlined in 8.2-8.6.

8.2 **Visual Examination**—The manifold shall be examined visually to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

8.3 **Hydrostatic Shell Test**—The manifold shall be hydro-statically tested by applying pressures equal to 1.5 times the manifold rated inlet and outlet pressures to the inlet and outlet ports, respectively, to check the structural integrity of the manifold. Pressure shall be applied for 5 min. Air or nitrogen may be used in lieu of water providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible fluid. There shall be no external leakage, permanent distortion, or structural failure.

8.4 **Relief-Valve Lift Test**—Pressure at the pressure-relief valve inlet shall be increased until the pressure-relief valve lifts. Pressure shall then be decreased until the pressure-relief valve resets. The pressure-relief valve shall lift and reseat within the limits specified in Specification F 1508. There shall be no evidence of operational instability or damage to the pressure-relief valve.

8.5 **Seat Tightness Test**—Handwheel-operated valves shall be seated with a torque not exceeding that specified in 6.5.3.3 (or the manufacturers’ recommendations, when less). Air, at the maximum inlet operating pressure each valve is subjected to in service, shall be used for seat leakage tests, using bubble fluid or immersing the outlet, or a line from the outlet, under water. The outlet stop valve shall also be tested in the outlet-to-inlet direction, applying pressure at the outlet of the valve equal to the maximum outlet-section rating of the manifold. Pressure-reducing valves shall be tested with an inlet pressure equal to the inlet rated pressure of the manifold. Pressure-relief valves shall be tested at the reseat pressure applicable to their setting in accordance with Specification F 1508. None of the valves shall show visible evidence of leakage over a 5-min period. The following procedure shall be used to check the pressure-reducing valve seat tightness: The valve shall be isolated downstream. The dead-ended volume shall be tight and shall not exceed ten diameters of downstream pipe. It shall be monitored with bubble fluid to assure tightness. With full-rated inlet pressure, there shall be no detectable rise in the outlet pressure over a 15-min period after manifold temperature stabilizes.

8.6 **External Leakage Test**—Air shall be applied at the appropriate rated pressure to each section of the manifold. External leakage shall be checked using bubble fluid or by submerging the manifold in water. There shall be no visible external leakage over a 5-min period.

9. **Marking**

9.1 **Identification Plate**—An identification plate of corrosion-resistant metal in accordance with Specification F 992; Types I, II, III, or IV shall be permanently attached to the manifold and shall include the following information (some or all information may instead be stamped or etched on the manifold blocks):

9.1.1 Manufacturer’s name,
9.1.2 ASTM designation and year of issue
9.1.3 Nominal operating conditions (inlet pressure, set pressure, and flow capacity), and
9.1.4 Manufacturer’s model/part number.

9.2 **Component Marking**—The pressure-reducing valve, pressure-relief valve, and each manual valve shall be marked or have an identification plate listing the manufacturer’s name and model/part number.

9.3 **Handwheel-Operated Valve Marking**—Each handwheel-operated valve shall be clearly marked to show its function in the manifold (for example, “Inlet Stop Valve,” “Outlet Stop Valve,” and “Bypass Throttle Valve”) and direction of operation of the handwheel movement to open or close the valve.

10. **Quality Assurance System**

10.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied. This system shall also ensure that all manifolds will perform in a similar manner to those representative manifolds subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the manifolds in the manufacturer’s plant to the extent specified on the purchase order.

11. **Keywords**

11.1 air systems; nitrogen systems; pressure-reducing manifolds
S1. Initial Qualification Testing

S1.1 Qualification tests shall be conducted at a facility satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.1.1 through S1.1.11 and delineated in the ordering data. The tests may be conducted on representative manifold sizes and pressure classes to qualify all sizes and pressure classes of manifolds, provided the manifolds are of the same type and design. Evidence of prior approval of these tests is acceptable.

S1.1.1 Examination Before Testing—The manifold shall be examined visually to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

S1.1.2 Relief-Valve Accumulation Test—The pressure-relief valve shall be tested for two conditions of accumulation capacity: (i) full-open pressure-reducing valve and (ii) full-open bypass valve. Maximum inlet operating pressure shall be maintained at the manifold inlet during this test. For the pressure-reducing valve portion, close the bypass valve, and block or otherwise modify the pressure-reducing valve to the wide-open fail condition. For the bypass valve portion, the pressure-reducing valve shall be isolated and the bypass valve fully opened. Under either condition, downstream pressure rise shall not exceed the accumulation pressure specified in Specification F 1508.

S1.1.3 Bypass Throttle Valve Functional Test—Minimum inlet operating pressure shall be maintained at manifold inlet. The pressure-reducing valve shall be isolated. The bypass throttle valve shall be opened until highest set pressure is maintained at maximum flow rate demand. Increase inlet pressure to maximum, then vary flow demand throughout the flow range of the manifold and verify ability of the bypass throttle valve to permit maintaining delivered pressure at the set point in a smooth, accurate manner.

S1.1.4 Bypass Throttle Valve Cycle Test—With maximum inlet pressure operating upstream, the bypass throttle valve shall be cyclic 100 times. There shall be no degradation to performance or evidence of damage or excessive wear. A cycle shall consist of a full opening and closing of the valve.

S1.1.5 Pressure Reversal Test—The manifold shall be tested to determine the susceptibility to damage when subjected to pressure reversal as specified in 6.5.1.1. It shall be set up with maximum inlet operating pressure and maximum set pressure. A separate means shall be included to insure that there is no loss of downstream pressure during this test. The reference load shall then be removed from the pressure-reducing valve set-point mechanism (if the pressure-reducing valve is spring loaded, all spring compression shall be backed off, if it is gas dome loaded, all dome charge shall be released). The inlet pressure shall then be released from the manifold, and this condition (no load on the pressure-reducing valve set point mechanism, zero pressure applied to the inlet side of the pressure-reducing valve seat, and maximum set pressure applied to the outlet side of the pressure-reducing valve seat) shall be maintained for a period of not less than 1 h. There shall be no leakage from the outlet to the inlet of the manifold. There shall be no evidence of damage to the pressure-reducing valve or any other portion of the manifold and no degradation to the performance capability of the manifold.

S1.1.6 Accuracy of Regulation Test—The manifold shall be tested for accuracy of regulation at each inlet pressure/set pressure combination defined below. At Condition D, flow shall be varied over the full range of flow rate demand as specified in Section 5. For Conditions A, B, and C, full-flow range testing is not required.

<td>maximum</td>
</tr>
</tbody>
</table>

During each sequence (changing from Condition A to Condition B and changing from Condition C to Condition D), no alteration shall be made to the set pressure adjustment, or any other portion of the manifold, and the accuracy of regulation shall be maintained as required by Table 4. There shall be no instability or other evidence of unsatisfactory operation of the manifold during these tests. Flow in each condition shall be maintained long enough to demonstrate that the above requirements are met.

S1.1.7 Pressurization Rate Test—With the rated inlet pressure upstream, and a depressurized downstream volume as specified in 6.5.3.5, each handwheel-operated valve shall be operated to demonstrate its ability to meet the pressurization rate as specified in 6.5.3.5.

S1.1.8 Shock Test—The manifold shall be subjected to and meet the high-impact shock tests for Grade A, Class I as specified in MIL-S-901 pressurized with water, air, or nitrogen. The inlet port shall be pressurized to the maximum inlet operating pressure and the outlet port pressurized to the maximum outlet operating pressure. There shall be no structural damage to the manifold or any components. There shall be no degradation to the performance capability of the manifold. Momentary loss in pressure is permissible.

S1.1.9 Vibration Test—The manifold shall be vibration tested in accordance with Type I of MIL-STD-167-1 pressurized with air or nitrogen. The inlet port shall be pressurized to the maximum inlet operating pressure and the outlet port pressurized to the maximum outlet operating pressure. At frequencies up to and including 33 Hz (unless otherwise specified in the ordering information, Section 5), there shall be
no resonance in the range of frequency tested. There shall be no structural damage or degradation to the performance capability of the manifold.

S1.1.10 Noise Test—The manifolds shall be tested for airborne noise in accordance with MIL-STD-740-1. The noise (sound pressure level) shall not exceed 85 dBA observed at 1-m distance from the manifold.

S1.1.11 Posttest Examination—The manifold shall be disassembled and examined for any evidence of excessive wear, degradation, or impending damage or breakage.

S2. Technical Data and Certification Requirements

S2.1 Drawings—Assembly drawings of the entire manifold and each component which clearly depict design shall be provided. The following shall also be included as part of the drawings content:

S2.1.1 Bill of material listing specification, grade, condition, and any other data required to identify fully the properties of the materials proposed. This shall include identifications, material and size designations, shore hardness, and any other data necessary to identify the parts fully.

S2.1.2 In cases in which standard commercial or military parts are or can be used, these shall be appropriately identified.

S2.1.3 Outline dimensions, disassembly space, location, and size of end connections and mounts.

S2.1.4 Estimated weight and center of gravity (vertical, longitudinal, and transverse).

S2.1.5 Recommended assembly torques or equivalent procedures for making up all joints and threaded assemblies.

S2.1.6 The following information shall be included:

S2.1.6.1 Regulation:
(a) Set pressure and adjustable range.
(b) Specified operating conditions—range of inlet pressures and required range of capacity.
(c) Fail-open capacity (for purposes of pressure-relief valve sizing) of the pressure-reducing valve.
(d) Wide-open capacity (for purposes of pressure-relief valve sizing) of bypass throttle valve.

S2.1.6.2 Overpressure Protection for Pressure-Relief Valve:
(a) Set pressure and adjustable range.
(b) Rated capacity—accumulation.
(c) Reset pressure.

S2.2 Technical Manuals—The following shall be included as part of the manual contents:

S2.2.1 The assembly drawings for the manifold, supplemented by additional illustrations where necessary to illustrate operation and maintenance adequately. These additional illustrations may consist of blowouts or partial or full sections and may eliminate extraneous lines and details to clarify the interaction of parts.

S2.2.2 Table listing wrench sizes and assembly torques (or other equivalent procedures) for making up all joints and threaded assemblies.

S2.2.3 Detailed disassembly and reassembly procedures. In addition to a section providing procedures for the complete disassembly and reassembly of the manifold, maintenance and troubleshooting sections shall contain, or refer to, only the limited disassembly and reassembly required to accomplish each particular operation. This is intended to reduce the possibility of unnecessary disassembly and unnecessary disturbance of adjustments when performing specific or limited maintenance or troubleshooting operations.

S2.2.4 Adjustment procedures for the pressure-reducing and pressure-relief valve. For the pressure-relief valve, provide the approximate relationship between turns of the adjusting screw and set pressure change.

S2.3 Certification—Certification shall be provided indicating that the valve meets all requirements of the purchase order.

S3. Quality Assurance

S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.

S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.

S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system that identifies status of material throughout all stages of manufacture.

S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.
S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.

S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.

S3.11 Nondestructive Examination—Provisions shall be made to use nondestructive examination, as necessary, to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer or qualified by a recognized national body or both, and their authorizations/qualification records shall be made available to the inspection authority if required.

S3.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.

S3.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.

S3.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during all stages of manufacture and shall be able to distinguish between inspected and uninspected material.

S3.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring, and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S3.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S3.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S3.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

S4. Special Material, Design, and Performance Considerations

S4.1 Recovered Materials—Unless otherwise specified herein, all equipment, material, and articles incorporated in the products covered by this specification shall be new and may be fabricated using materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. The term “recovered materials” means materials that have been collected or recovered from solid waste and reprocessed to become a source of raw materials, as opposed to virgin raw materials. None of the above shall be interpreted to mean that the use of used or rebuilt products is allowed under this specification unless otherwise specified.

S4.2 Pipe threads shall not be used in the manifold.

S4.3 Manifold performance shall not be adversely affected by the following line and ambient conditions:

S4.3.1 Ambient Atmospheric Conditions:
S4.3.1.1 Temperature: 40 to 120°F (4 to 49°C).
S4.3.1.2 Moisture content: Exposure to atmosphere containing salt-laden moisture.

S4.3.2 Quality of Inlet Air/Gas—Air or nitrogen moisture content between the limits of +20°F (−7°C) to −60°F (−50°C) dewpoint at 4500-psig (31.0-MPa gage pressure). Particulate contamination: Protected by 5-μm nominal/18-μm absolute filtration.

S4.4 Gage Connections—The ¼-in. (DN8) threaded gage connection (see 6.4.7) shall be in accordance with MS 16142.

This standard is issued under the fixed designation F 1716; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope
1.1 This guide covers a recommended plan for transition and acceptance of marine software that was developed by an activity other than the maintaining activity. It further provides a recommended iterative process model for managing and executing software maintenance activities.

2. Referenced Documents
2.1 ASTM Standards:
E 622 Guide for Developing Computerized Systems
E 919 Specification for Software Documentation for a Computerized System
E 1013 Terminology Relating to Computerized Systems

2.2 IEEE Standards:
100 Standard Dictionary for Electrical and Electronic Terms
610 Standard Glossary of Software Engineering Terminology
1063 Standard for Software User Documentation
1074 Standard for Developing Software Life Cycle Processes
1219 Standard for Software Maintenance

2.3 ANSI Standards:

2.4 Military Standards and Specifications:
MIL-STD 498 Software Development and Documentation

3. Terminology
3.1 The terminology used in this guide is defined in Terminology E 1013 and Guide E 622.
3.2 Other computer-related terms in this guide are defined in IEEE 100 and IEEE 610.12.

4. Significance and Use
4.1 This guide provides a recommended transition plan for a marine software maintainer, when the maintainer is other than the supplier, to develop the capability to make extensive changes or extensions to the programs. Further, this guide provides a recommended interactive process model for managing and executing software maintenance activities. This guide applies principally to the marine software that requires design effort and for which the product requirements are stated principally in performance terms.

5. Software Transition Plan
5.1 The software transition plan is developed when the software support concept calls for transition of responsibility from the developer to a separate support agent. The software transition plan identifies hardware, software, and other resources needed for life cycle support of deliverable software and describes the developer’s plans for transitioning deliverable items to the support agent. The developer shall identify all software development resources needed by the support agent to fulfill the support concept specified in the contract. The developer shall develop and record plans identifying these resources and describing the approach to be followed for transitioning deliverable items to the support agent. The planning shall include the following.

5.1.1 Software Support Resources—Description of the resources needed to support the deliverable software. These resources shall include items needed to control, copy, and distribute the software and its documentation, and to specify, design, implement, document, test, evaluate, control, and distribute modifications to the software. This includes needed
compilers, linkers, locators, mappers, and tools such as configuration utilities. In addition, include as applicable, any special operating systems.

5.1.2 Facilities—Description of the facilities needed to support the deliverable software. These facilities may include special rooms, mock-ups, special power requirements, and so forth.

5.1.3 Hardware—Identification and description of the hardware and associated documentation needed to support the deliverable software. This hardware may include computers, peripheral equipment, hardware simulators, stimulators, emulators, diagnostic equipment, and non-computer equipment. The description shall include:

5.1.3.1 Specific models, versions, and configurations.
5.1.3.2 Rationale for the selected hardware.
5.1.3.3 Reference to user/operator manuals or instructions for each item, as applicable.
5.1.3.4 Identification of each hardware item and document as acquirer-furnished, any item that will be delivered to the support agent, any item the support agent is known to have, any item that will be delivered to the support agent shall address the following:

5.1.3.5 When items must be acquired, information about a current source of supply, including whether the item is currently available and whether it is expected to be available at the time of delivery.
5.1.3.6 Information about manufacturer support, licensing, and data rights, including whether the item is currently supported by the manufacturer, whether it is expected to be supported at the time of delivery, whether licenses will be assigned to the support agent, and the terms of such licenses.
5.1.3.7 Privacy considerations or limitations.
5.1.4 Software—Identification and description of the software and associated documentation needed to support the deliverable software. This software may include computer-aided software engineering (CASE) tools, data in these tools, compilers, test tools, test data, simulations, emulations, utilities, configuration management tools, databases and data files and other software. The description shall include:

5.1.4.1 Specific names, identification numbers, version numbers, release numbers, and configurations, as applicable.
5.1.4.2 Rationale for the selected software.
5.1.4.3 Reference to user/operator manuals or instructions for each item, as applicable.
5.1.4.4 Identification of each software item and document as acquirer-furnished, any item that will be delivered to the support agent, any item the support agent is known to have, any item the support agent must acquire, or other description of status.
5.1.4.5 When items must be acquired, information about a current source of supply, including whether the item is currently available and whether it is expected to be available at the time of delivery.
5.1.4.6 Information about vendor support, licensing, and data rights, including whether the item is currently supported by the vendor, whether it is expected to be supported at the time of delivery, whether licenses will be assigned to the support agent, and the term of such licenses.

5.1.4.7 Privacy considerations and limitations.
5.1.4.8 Certification of virus protection measures taken including identification and version of software used.
5.1.5 Other Documentation—Identification of any other documentation needed to support the deliverable software. This list will include, for example, plans, reports, studies, specifications, design descriptions, test cases/procedures, test reports, user/operator manuals, and support manuals for the deliverable software, including the following:

5.1.5.1 Names, identification numbers, version numbers, and release numbers, as applicable.
5.1.5.2 Rationale for including each document.
5.1.5.3 Identification of each document as acquirer-furnished, any item that will be delivered to the support agent, any item the support agent is known to have, any item the support agent must acquire, or other description of status.
5.1.5.4 When a document must be acquired, information about where to acquire it.
5.1.5.5 Information about licensing and data rights.
5.1.5.6 Privacy and limitations.
5.1.5.7 Beta Testing and Verification and Validation Records—Records of Beta Testing and Verification and Validation shall be provided if applicable.
5.1.5.8 Description of significant problems and changes made during the development process.
5.1.6 Personnel—Description of the personnel needed to support the deliverable software, including anticipated number of personnel, and types and levels of skills and expertise.
5.1.7 Other Resources—Identify any other resources needed to support the deliverable software, including consumables.
5.1.8 Interrelationship of Components—Identify interrelationships of the components identified above. Figures may be used to show interrelationships.
5.1.9 Recommended Procedures—Describe any procedures, including advice and lessons learned, that the developer may wish to recommend to the support agent for supporting the deliverable software and associated support environment.
5.1.10 Training—Describe the developer’s plans for training support personnel to support the deliverable software.
5.1.11 Anticipated Areas of Change—Describe anticipated areas of change to the deliverable software.
5.1.12 Transition Planning—Planning shall be performed for all activities to transition the deliverable software to the support agent. Plans for transitioning the deliverable software to the support agent shall address the following:

5.1.12.1 The activities to be performed to transition the deliverable software to the support activity. These activities may include planning/coordination meetings; preparation of items to be delivered to the support agent; packing, shipment, installation, and checkout of the software support environment; packing, shipment, installation and checkout of the operational software; and training of the support personnel.
5.1.12.2 Designation of the roles and responsibilities for each activity.
5.1.12.3 The resources needed to carry out the transition activities and which party will perform each activity.
5.1.12.4 Schedules and milestones for conducting the transition activities.
5.1.12.5 Procedures for installation and checkout of the deliverable items of the support environment.

6. Software Maintenance
6.1 System software maintenance commences after the transition and acceptance of the developed software by the software support activity. Software maintenance can be identified by either user/customer or system maintainer. The processes of IEEE 1219 are recommended as a model for software maintenance.

7. Support Agent Software Process Maturity
7.1 The processes of the software support agent are recommended to be certified to at least Level Two as defined in the Software Engineering Institute (SEI) Capability Maturity Model for Software Version 1.1,6 equivalent to ANSI/ISO/ASQC Q 9000-3.

8. Keywords
8.1 computerized systems; marine technology; ships; software; software maintenance; software support

Standard Specification for
Rotary Positive Displacement Distillate Fuel Pumps

This standard is issued under the fixed designation F 1718; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the requirements applicable to the design and construction of rotary positive displacement distillate fuel pumps for shipboard use.

1.2 Lineal dimensions and units of force in this specification are expressed as inches and pounds respectively. A companion metric standard is in the process of preparation.

B 271 Specification for Copper-Base Alloy Centrifugal Castings
B 505 Specification for Copper-Base Alloy Continuous Castings
B 584 Specification for Copper Alloy Sand Castings for General Applications
D 1418 Practice for Rubber and Rubber Lattices—Nomenclature
D 2000 Classification System for Rubber Products in Automotive Applications
D 3951 Practice for Commercial Packaging
F 104 Classification System for Nonmetallic Gasket Materials
F 467 Specification for Nonferrous Nuts for General Use
F 468 Specification for Nonferrous Bolts, Hex Cap Screws, and Studs for General Use
F 593 Specification for Stainless Steel Bolts, Hex Cap Screws, and Studs
F 594 Specification for Stainless Steel Nuts
3. Terminology

3.1 Definitions:

3.1.1 capacity, \( n \)—the quantity of fluid actually delivered per unit of time at the rated speed, including both the liquid and dissolved or entrained gases, under stated operating conditions.

3.1.2 Discussion—In the absence of any gas or vapor entering or forming within the pump, the capacity is equal to the volume displaced per unit of time, less slip.

3.1.3 capacity, maximum, \( n \)—the quantity of fluid delivered that does not exceed the limit determined by the formula in 4.1.2.1.

3.1.4 capacity, rated, \( n \)—the minimum quantity of fluid delivered at the specified conditions of discharge pressure, inlet pressure and viscosity as shown in Table 1.

3.1.5 displacement, \( n \)—the volume displaced per revolution of the rotor(s).

3.1.6 Discussion—In pumps incorporating two or more rotors operating at different speeds, the displacement is the volume displaced per revolution of the driving rotor. Displacement depends only on the physical dimensions of the pumping elements.

3.1.7 dry operation, \( n \)—a brief run during priming or stripping with suction and discharge lines unrestricted and pump chamber wet with liquid but pumping only air or vapor available from the suction.

3.1.8 efficiency, mechanical, \( n \)—the ratio of the pump power output (hydraulic horsepower) to the pump power input (brake horsepower) expressed in percent.

3.1.9 efficiency, volumetric, \( n \)—the ratio of the pump’s capacity to the product of the displacement and the speed expressed in percent.

3.1.10 fuel, clean, \( n \)—fuel purified for direct use.

3.1.11 fuel, dirty, \( n \)—fuel before purification that may contain water and some solids.

3.1.12 net positive inlet pressure available (NIIPA), \( n \)—the total inlet pressure available from the system at the pump inlet connection at the rated flow, minus the vapor pressure of the liquid at the pumping temperature.

3.1.13 net positive inlet pressure required (NIIPR), \( n \)—the net pressure above the liquid vapor pressure at rated flow and pumping temperature and at the pump inlet connection required to avoid performance impairment due to cavitation.

3.1.14 pressure, cracking, \( n \)—sometimes called set pressure, start-to-discharge pressure, or popping pressure; the pressure at which the relief valve just starts to open.

3.1.15 Discussion—This pressure cannot be determined readily in a relief valve that bypasses the liquid within the pump.

3.1.16 pressure, differential, \( n \)—the difference between discharge pressure and inlet pressure.

14 Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.
15 Available from Society of Automotive Engineers, 400 Commonwealth Dr., Warrendale, PA 15096.
17 Available from American Gear Manufacturers Association, Suite 1000, 1901 N. Fort Myer Dr., Arlington, VA 22209.
18 Available from Standardization Documents Order Desk, Bldg. 4, Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.
3.1.17 **pressure, discharge, n**—the total pressure at the outlet of the pump; discharge pressure is sometimes called outlet pressure.

3.1.18 **pressure, inlet, n**—the total pressure at the inlet of the pump. Inlet pressure is sometimes called suction pressure.

3.1.19 **pressure, maximum allowable working, n**—the maximum continuous pressure for which the manufacturer has designed the equipment (or any part to which the term is referred) when handling the specified fluid at the specified temperature.

3.1.20 **Discussion**—This pressure should not be greater than two thirds of the hydrostatic test pressure of the pressure containing parts.

3.1.21 **rated condition, n**—defined by discharge pressure, inlet pressure, capacity, and viscosity.

3.1.22 **rotary pump, n**—a positive displacement pump consisting of a casing containing gears, screws, lobes, cams, vanes, shoes, or similar elements actuated by relative rotation between the drive shaft and the casing.

3.1.23 **Discussion**—There are no inlet and outlet valves. The rotors are characterized by their close running clearances.

3.1.24 **slip, n**—the quantity of fluid that leaks through the internal clearances of a rotary pump per unit of time.

3.1.25 **Discussion**—Slip depends on the internal clearances, the differential pressure, the characteristics of the fluid handled and in some cases, the speed.

3.1.26 **speed, maximum allowable, n**—in revolutions per minute, the highest speed at which the manufacturers’ design will permit continuous operation.

3.1.27 **speed, minimum allowable, n**—in revolutions per minute, the lowest speed at which the manufacturers’ design will permit continuous operation.

3.1.28 **speed, rated, n**—the number of revolutions per minute of the driving rotor required to meet the rated conditions.

3.1.29 **suction lift, n**—a term used to define a pump’s capability to induce a partial vacuum at the pump inlet.

3.1.30 **temperature, maximum allowable, n**—the maximum continuous temperature for which the manufacturer has designed the equipment (or any part to which the term is referred) when handling the specified fluid at the specified pressure.

3.1.31 **unit, pump, n**—the pump and motor assembly; it also includes a gear box, base, couplings, guards, as required.

### 4. Classification

4.1 Pumps shall be classified as follows:

4.1.1 **Types:**

4.1.1.1 **Type II**—Screws with timing gears.

4.1.1.2 **Type III**—Screws without timing gears.

4.1.1.3 **Type IV**—Impellers with timing gears.

4.1.1.4 **Type V**—External gear (spur, helical, herringbone, lobe).

4.1.1.5 **Type VIII**—Internal gear, internal rotary lobe.

4.1.1.6 **Type X**—Vane (sliding).

4.1.1.7 **Type XI**—Sliding shoe.

4.1.2 **Sizes:**

4.1.2.1 Standard pump sizes shall be as shown in Table 1. Rated capacity shall be based on 150-psig discharge pressure, 10-psig inlet pressure and 32-SSU viscosity (1034-kPa gage, 69 kPa absolute, and 2 centistoke, respectively). Rated capacity equals the minimum capacity. The maximum capacity shall not exceed the amount determined by the following formula:

\[ Q_{\text{max}} = Q \left[ 1 + \frac{1}{1 + G^4} \right] \]  

where:

\[ Q = \text{the rated capacity (minimum capacity)} \]  
\[ Q_{\text{max}} = \text{maximum allowable capacity, at 32-SSU viscosity} \]

4.1.2.2 **Discussion**—The minimum capacity shall be rounded to nearest whole number.

4.1.2.3 **Discussion**—The maximum capacity shall not exceed the amount determined by the following formula:

\[ Q_{\text{max}} = Q \left[ 1 + \frac{1}{1 + G^4} \right] \]  

where:

\[ Q = \text{the rated capacity (minimum capacity)} \]  
\[ Q_{\text{max}} = \text{maximum allowable capacity, at 32-SSU viscosity} \]

### 5. Ordering Information

5.1 The ordering activity is to provide the following information to the potential bidders:

5.1.1 **Title, number, and date of specification.**

5.1.2 **Type and size of each pump (see Section 4).**

5.1.3 **Quantity of each pump type and size (see Table 1).**

5.1.4 **Mounting configuration (vertical, horizontal).**

5.1.5 **Motor characteristics and specifications (see 7.6 and motor specification if applicable).**

5.1.6 **Discharge pressure.**

5.1.7 **System relief valve cracking pressure and full flow bypass pressure (see 7.6 and 7.15).**

5.1.8 **Preservation, packaging, packing, and boxing requirements (see Section 14).**

5.1.9 **Quantity of drawings (see 13.2).**

5.1.10 **Quantity of manuals (see 13.3).**

5.1.11 **Format and quantity of each type of test report (see 12.1.1.4 and S12.3.8).**

5.1.12 **Shock, noise, and vibration requirements, if applicable (see S12.3).**

5.1.13 **Types of certified data required (see 12.1.2).**

5.1.14 **Instruction plates and locations, if required.**

5.1.15 **Define shipbuilding specification, if applicable (see 13.1).**

### 6. Materials

6.1 Pump component parts shall be constructed of the materials shown in Table 2.

### 7. General Requirements

7.1 **Pumps shall be designed to pump distillate fuel and aviation turbine fuel with a viscosity range of 32 to 100 SSU (2 to 21 cSt).**

7.2 Pumps shall be capable of sustained operation during inclinations up to 45° in any direction.

7.3 The pumps shall be capable of withstanding environmental vibration induced by shipboard machinery and equipment in the frequency range of 4 to 25 Hz.

7.4 The internally excited vibration levels of the pump shall not exceed 0.003-in. (0.076-mm) displacement peak to peak during rated operation when readings are measured on the pump case near the coupling perpendicular to the pump shaft.

7.5 At the conditions in 4.1.2, the airborne noise level of the pump unit shall meet the requirements in Table 3.

7.6 The pump shall be driven by an electric motor. The driver shall be sized for maximum flow at the relief valve full flow bypass pressure, at maximum viscosity.
7.7 If a reduction gear is required between the driver and the pump, it shall be provided by the pump manufacturer. Reduction gears shall meet the requirements of the American Gear Manufacturers Association Gear Handbook Volume 1, AGMA 390.03. Minimum acceptable gears are AGMA Class 7 and minimum acceptable pinions are AGMA Class 8. Bearings shall be designed for a minimum L10 life of 15,000 h.

7.8 All pump units shall incorporate guards over couplings, belts, and other external rotating parts. The guards shall prevent personnel contact with the rotating elements. Guards shall be rigid enough to support a 200-lb (88-kg) person standing on it.

7.9 The seating surfaces of mounting bedplates, bracket mounting plates, or other mounting arrangements shall be machined.

7.10 Mounting bedplates, brackets, and plates shall be provided with holes of sufficient size and quantity to ensure adequate attachment to shipboard foundation or mounting structure. Means shall be provided for attaching lifting gear for installation or removal.

7.11 Vertical units with face mounted motors shall be arranged so there are four possible orientations of motor driver to pump. Other drivers are to be oriented per the ordering data.

7.12 Vertical units that are motor driven shall be assembled with the conduit box mounted over the pump inlet flange, unless otherwise specified.

7.13 Couplings between pump and driver shall be keyed to both shafts.

---

7.7 If a reduction gear is required between the driver and the pump, it shall be provided by the pump manufacturer. Reduction gears shall meet the requirements of the American Gear Manufacturers Association Gear Handbook Volume 1, AGMA 390.03. Minimum acceptable gears are AGMA Class 7 and minimum acceptable pinions are AGMA Class 8. Bearings shall be designed for a minimum L10 life of 15,000 h.

7.8 All pump units shall incorporate guards over couplings, belts, and other external rotating parts. The guards shall prevent personnel contact with the rotating elements. Guards shall be rigid enough to support a 200-lb (88-kg) person standing on it.
8. Pump Design

8.1 The pump inlet and outlet connections shall be flanged. Nonferrous material flanges shall be in accordance with ANSI B16.24 flat face, unless otherwise stated in the ordering data. Spool piece adapters (threaded and seal welded, or O-ring sealed to the pump case on one end and flanged on the other end) may be furnished to meet the flanged inlet and outlet requirement.

8.2 The pump cases shall be equipped with vent, drain, inlet, and outlet gage connections. The connection shall be straight thread with O-ring seal. Tapered pipe thread connections are prohibited. Small pumps do not require these connections.

8.3 The pumps shall be equipped with radial and thrust bearings as necessary to counteract any unbalanced forces in the pump and to ensure that the pump will operate satisfactorily under the conditions stated in 7.2.

8.4 The bearings shall be securely fitted (by snap rings or shoulders or other means) to prevent axial movement. Bearing housings shall be integral to the pump case or secured to the pump case in such a manner as to ensure alignment. Usage of bolts alone is not considered sufficient to ensure alignment.

8.5 The bearings may be sealed and self or externally lubricated or may be lubricated by the liquid being pumped.

8.6 The rolling contact bearings shall be selected in accordance with AFBMA standards and shall have a minimum L10 life of 15,000 h as calculated in accordance with AFBMA Standard 9 or 11 as appropriate.

8.7 The pumps shall be equipped with mechanical shaft seals in accordance with Specification F 1511. The installation shall ensure that adequate circulation of liquid at the seal faces occurs to minimize deposit of foreign matter and to provide adequate lubrication of the seal faces.

8.8 The mechanical seals shall be positioned or located on the shaft axially, by a positive means such as a stub, step, or shoulder positively located on the pump shaft. Set screws shall not be used to position seals or seal sleeves axially. An antirotation pin shall be provided for shaft sizes 1 in. and larger to prevent the mechanical seal-mating ring from rotation, if required by the ordering document.

8.9 The pump head or end covers, or both, shall be located to the pump case by a means such as rabbet, dowels, or pilot to ensure proper alignment.

8.10 The rotors and timing gears shall be machined and positively secured in position to maintain required clearances and prevent undue wear.

8.11 The fasteners shall be selected from Table 2, taking into consideration temperature of operation, mechanical properties, and corrosion resistance.

8.12 The pumps shall be provided with removable liners in pump sizes “C” or larger.

9. Performance Requirements

9.1 Pumps of each size shall deliver a capacity within the respective ranges shown in Table 1 when tested at 10-psia (69-kPa absolute) inlet pressure, 150-psi (1034-kPa) discharge pressure, and a fluid viscosity of 32 SSU.

10. Painting and Coatings

10.1 Painting—External unmachined and nonmating machined surfaces shall be thoroughly cleaned and painted with a fuel resistant, anticorrosive (lead and chromate free) primer and topcoat.

10.2 Painting external surfaces of nonferrous parts and components is not required but is permissible to avoid excessive masking. Identification and information plates should not be painted or over sprayed.

11. Equipment Identification Plates

11.1 The identification plates shall be made of brass or stainless steel and furnished on each pump unit.

11.2 The plates shall be secured to equipment with corrosion-resistant metallic fasteners.

11.3 The pump unit identification plates shall contain data as follows:

11.3.1 Manufacturer’s name.

11.3.2 Manufacturer’s model and type size.

11.3.3 Service application.

11.3.4 Manufacturer’s serial number.

11.3.5 Salient design characteristics if applicable.

11.3.5.1 Capacity.

11.3.5.2 Discharge pressure.

11.3.5.3 Pump rated speed (r/min).

11.4 Accessory units, such as the driver and gearbox, shall have an identification plate in accordance with the applicable equipment specification. If not specified, the manufacturer shall use its commercial nameplate.

12. Testing Requirements

12.1 The pump manufacturer shall perform the following tests at the manufacturing facility or approved test facility. Equipment for specified tests shall be provided by the manufacturer.

12.1.1 Performance Acceptance Tests—Each pump shall meet the following performance acceptance tests.

12.1.1.1 Mechanical Running Test—The pump shall be tested at rated condition of 150-psig discharge pressure, 10-psia inlet pressure, and 32 (+13/ −0) SSU viscosity to demonstrate that the pump is capable of delivering the required capacity as shown in Table 1.

12.1.1.2 Noise Tests—For pumps provided with drivers (units), each unit shall be tested to demonstrate the ability to meet the requirements of 7.5, if required by 5.1. The unit shall be operated at the discharge pressure (5.1.6) for these tests.

12.1.1.3 Hydrostatic Tests—Pressure-containing parts or the entire pump shall be tested hydrostatically with liquid to 225 psig for 10 min. The assembled pump shall be hydrostatically tested to 50 psig for 5 min. The tests shall be considered
satisfactory when no leaks are observed. Seepage past blanking plates and seepage of other sealing apparatus to perform the test is allowed. Operation of the hydrostatic test pump to maintain pressure is acceptable.

12.1.1.4 Test Reports—A test report shall be submitted for each test conducted. Quantity and format as defined in the ordering data.

12.1.2 Certified Data—Certified performance data shall be supplied when required. Testing and reporting as defined by ANSI/HI 3.6 for Type IV, Level A tests. See 5.1.13.

13. Technical Documents

13.1 General—Drawings and technical manuals shall be submitted in an electronic format that is ISO 9066 compliant. When this specification is invoked in a shipbuilding specification, the shipbuilding specification shall take precedence for technical documentation requirements. When this specification is used for spares, replacements, or requirements without technical documentation requirements, the following paragraphs apply.

13.2 Drawings:

13.2.1 Unit Drawings—An outline or top drawing of the unit (pump and driver) shall be furnished. Length, width, height, mounting details, and connections shall be dimensioned. Brackets, bedplates, guards, couplings, identification plates, rotation arrows, and so forth shall be shown on the drawing. The weight and center of gravity (calculated or actual) of the unit shall be indicated on the drawing.

13.2.2 Pump Drawings—Pump drawings shall include a sectional assembly drawing. The sectional assembly drawing shall contain a complete list of materials or reference to a list of materials drawing, which shall be provided. Any subassembly made up of parts that require special alignment or assembly methods that cannot be disassembled, repaired, and reassembled onboard ship without the use of special tools and jigs shall be indicated as a subassembly in the list of material. The weight and center of gravity (calculated or actual) of the pump shall be indicated on the drawing.

13.2.3 Associated Equipment Drawings—Drawings for driver and associated equipment shall be in accordance with their respective specifications.

13.2.4 Performance Curves—Complete performance curves shall be furnished. The curves may be on graphs that can be printed on notebook size paper. Format as defined by ANSI/HI 3.6.

13.3 Technical Manuals—Instruction books or technical manuals shall be prepared for each different type or size of pump installed. A single manual shall contain not more than one type or size of pump. However, when several pumps are installed in a ship that are identical except for type of driver, they may be included in a single manual. Piece (item or find) numbers of parts referred to in technical manuals shall match the piece numbers shown on pump drawings. Technical manuals shall contain reproductions of pump drawings.

14. Packaging and Preservation

14.1 Packaging—Pumps, pump units, and accessories shall be packaged per Practice D 3951 for warehouse storage and the following:

14.1.1 Packaging for Domestic Shipment—Pumps, components, and units to be used within six months may be packaged using standard commercial packaging. For storage of greater than six months or when multiple handlings are anticipated, package to ensure prevention of pilferage and resistance to damage from multiple handlings.

14.1.2 Packaging for Overseas Shipment—Packaging and marking for overseas shipments shall include sufficient protection from adverse atmospheric conditions and exposure to worst case handling and storage problems. All products shall be protected with water-resistant packaging material for the exterior shipping container, either treated corrugated cartons or boxes built from mildew resistant lumber, depending on the weight of the product or the configuration of the load.

14.2 Preservation—Items susceptible to deterioration or damage from environmental elements shall be preserved. Noncoated ferrous surfaces shall be preserved.

14.3 Cushioning and Bracing—Items susceptible to damage during shipment and handling shall be cushioned or shall be securely braced or blocked, or both, within the shipping container, to avoid damage.

14.4 Container Marking—Containers, boxes, or packages shall be clearly marked with the ship to address, contract or purchase order number, shipping point address, item nomenclature, and bar codes. The lifting points and orientation markings shall be clearly visible.

15. Quality Requirements

15.1 The manufacturer shall have a certified ISO 9001 quality system.

16. Keywords

16.1 distillate fuel pump; fuel pump; positive displacement pump; pump; rotary pump
The following supplementary requirements established by the U.S. Navy, Commander Naval Sea Systems Command (NAVSEA) shall apply when specified in the contract or purchase order. When there is a conflict between the specifications and this Supplement, requirements of the Supplement shall take precedence.

S6.2 Materials other than shown in Table 2 are considered exceptions and are subject to approval by NAVSEA.

S7.3 The pumps shall be capable of withstanding environmental vibration induced by shipboard machinery and equipment in the frequency range of 4 to 25 Hz and be in accordance with MIL-STD-167-1 Type I. Maximum single frequency displacement (double amplitude) in the 4- to 15-Hz range is 0.060 in. (1.524 mm) and in the 16- to 25-Hz range is 0.040 in. (1.016 mm).

S7.4 The internally excited vibration levels of the pump shall be in accordance with MIL-STD-167-1 Type II and shall not exceed 0.003-in. (0.076-mm) displacement peak to peak during rated operation when readings are measured on the pump case near the coupling perpendicular to the pump shaft.

S7.5 At the conditions in 4.1.2, the airborne noise level of the pump unit shall meet the requirements in Table 3 (see MIL-STD-740-1).

S7.6 At the conditions in 4.1.2, the structureborne noise level of the pump unit shall meet the requirements in Table S1.1 (see MIL-STD-740–2).

S7.19 Pumps shall meet the requirements of MIL-S-901 HI (High Impact) Shock, Grade A.

S8.7 Mechanical shaft seals shall be in accordance with Specification F 1511, including Supplement S1.

S12.3 Qualification Tests—The first pump of each size, type, or design shall meet the following qualification tests. All tests shall be performed with the motor size required at rated condition as indicated in 4.1.2.

S12.3.1 Performance Test—The pump shall be tested at rated condition of 150-psig discharge pressure, 10-psia inlet pressure, and 32 (+13/−0) SSU viscosity to demonstrate that the pump is capable of delivering the required capacity as shown in Table 1. Record all test data, including electrical power input, for comparison to performance retest results (see S12.3.7).

S12.3.2 Vibration Type II Test—The pump shall be tested to demonstrate the ability to meet the requirements of S7.4. Record all test data, including electrical power input, for comparison to performance retest results (see S12.3.7).

S12.3.3 Noise Tests—The pump shall be tested to demonstrate the ability to meet the requirements of S7.5 and S7.6. Record all test data, including electrical power input, for comparison to performance retest results (see S12.3.7).

S12.3.4 Vibration Type I Test—The pump shall be tested to demonstrate the ability to meet the requirements of S7.3.

S12.3.5 Shock Test—The pump shall be tested to demonstrate the ability to meet the requirements of S7.19.

S12.3.6 Endurance Test—The endurance test shall consist of a running test of not less than 500 h of actual running time at rated condition. The 500 h shall be broken by at least three rest periods of 8 h or more each. A minimum of ten start-stop cycles shall be performed during the course of the test.

S12.3.7 Performance Retest—Upon completion of the tests in S12.3.1 through S12.3.6, repeat the performance test (S12.3.1), the vibration type II test (S12.3.2), and the noise test (S12.3.3). Record all test data.

S12.3.8 Test Reports—A test report shall be submitted for each test conducted. Quantity and format as defined in the ordering data.
Standard Guide for
Marine Vessel Structural Inspection Considerations

This standard is issued under the fixed designation F 1754; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide covers information to develop and implement a marine vessel inspection process. It is intended to provide considerations for persons interested in planning, organizing, and implementing a structural survey plan for a marine vessel, especially during the design phase of the vessel. It is intended to be used in conjunction with any other required inspection or survey requirements but can form the basis for such planning in the absence of other such applicable requirements.

1.2 This guide provides owners, operators, shipyards, and designers with a plan for developing a detailed inspection process that covers all stages of the operating life of a marine vessel, including the design, construction, and in-service periods. This plan may be developed and used in concert with classification society and flag state surveys and inspections.

1.3 This guide also provides the basis for development of a recommended corrective action plan for typical structural deficiencies or deviations, or both.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

1.5 All portions of this guide may not be applicable to all vessels or shipyards since many yard-specific standards to ensure contracted level of quality are in existence.

2. Referenced Documents

2.1 ASTM Standards:  

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 blind spots, n—areas of a vessel’s structure that cannot be visibly or electronically inspected for failure.

3.1.2 large tanks, n—tanks of such dimension as to have uninspectable heights greater than 10 m.

3.1.3 telltale areas, n—areas of a ship’s structure identified by analyses and investigations during design development as being subject to higher stresses or more susceptible to fatigue than others, even though the higher stresses are still within allowable limits. Also, areas identified after the vessel is placed in service that continue to experience active or recurring cracking in the watertight envelope or that affect the structural integrity of the vessel.

4. Introduction

4.1 As stated earlier, the intent of this guide is to assist in the preparation of an inspection plan for a marine vessel during its design, construction, and in-service stages and to plan for inspection during the design. This guide should be used in the preparation of a specific inspection program for the construction of a specific marine vessel. It is not intended to set any stringent requirements for the structural inspections of any particular vessel. The suggestions for various inspection considerations in this guide are presented for the purpose of making available for review and use a broad set of guidelines.

4.2 This guide is applicable to all commercial and pleasure marine vessels. Although the references generally apply to steel and aluminum welded hulls, the overall aspects may be applied to any material or type of construction.

4.3 At any point of its construction or service life, the vessel may require classification society or flag state regulatory inspections, or both, as well as shipowner’s surveys. The surveys, depending on occasion, should consider the general condition of the vessel, provide a detailed condition assessment, obtain data to determine corrosion rate and damage, or obtain information for repair specification development, or a combination thereof. The inspection plan should take into account all of these types of information in its development. On occasions, the surveys also should obtain data on rate of coating breakdown.

4.4 Because of severe loadings, excessive wastage, poor structural design, improper use of materials, excessive fatigue cycling, and so forth, failure may occur at any structure component at some stress value that is much less than the theoretically allowable limit. Therefore, detection of such
conditions by careful analysis and by sufficient inspection throughout the entire process is consequently crucial for the prevention of failure. This guide describes generically the extent of and the procedures for inspections to be performed at each stage of a marine vessel’s life. Minor and major imperfections can be detected early in the construction process. Therefore, structural integrity can be maintained with periodic in-service inspections and appropriate and timely corrective measures to prevent any accumulation of defects or costly rework.

4.5 From construction and early service life inspections, a structural history of the vessel can be prepared forming the basis on which future in-service inspection results can be evaluated.

5. Inspection Considerations During Design Stages

5.1 To ensure the marine vessel’s structural integrity, the designers should consider the following inspection-related requirements during the design stages:

5.1.1 Inspectability of a Marine Vessel’s Structure During Construction and In-Service:

5.1.1.1 Background—During the life of any marine vessel, several inspections are conducted on the structure. These consist of two types that directly reflect their purpose, convenience and regulatory. In conducting either one, certain locations require access that are not readily accessible without climbing the structure or obtaining assistance from mechanical devices. When an inspection requires the use of mechanical means to access the structure, several options are available. They include anything from a simple platform elevated by a hoist connected at the overhead to a sophisticated ROV (Remote Operated Vehicle) that permits the inspector to remain outside the tank altogether. An issue that must be recognized is the definition of the “degree of inspection” has a direct bearing on the conclusions drawn from information presented herein.

5.1.1.2 For the purposes of this guide, the following assumptions are made relative to the degree of inspection:

5.1.1.3 The inspected structure must be in direct line of sight.

5.1.1.4 The inspected structure must be in clear and distinct view, taken as a distance of not more than 1.5 m (5 ft) from one’s eyes.

5.1.1.5 The structure is to be inspected to a degree that would reveal almost all fractures that have a length of 50 mm (2 in.) or more. This depends significantly on the cleanliness, lighting level, stress, and so forth, of the structure.

5.1.1.6 The inspection shall be conducted in a continuous manner such that the shortest amount of time is taken for it.

5.1.1.7 For the purposes of inspection, the structure should be broken down into discrete zones, such as those depicted in Fig. 1. Where the structure differs from that depicted in Fig. 1, an appropriate scheme of identifying zones for inspection should be adopted.

(1) Zone 1—The bottom and inner bottom shell structure including the turn of bilge and any structure attached to them.

(2) Zone 2—The deckhead structure, from ship’s side to ship’s side, including the stiffening attached to it.

(3) Zone 3—The side shell structure, including the side bulkhead structure for double hull vessels, including the stiffening attached to it.

(4) Zone 4—The longitudinal bulkhead structures that include the centerline and side longitudinal bulkheads, except a side bulkhead of a double hull structure.

(5) Zone 5—The transverse bulkhead structure, fore and aft sides, extending from the bottom shell to the deckhead.

5.1.2 Access Methods:

5.1.2.1 Fixed Staging—This method consists of poles, fittings, planks, and ladders that create a tower or walkway. This is the only method that permits access to all structural areas of a vessel. To achieve this coverage, however, it is very expensive and time consuming. A simple description of the method could be compared to an erector set. It is a straightforward method to which most people can relate. It may be a method that more people feel comfortable using than some. Accessing a deckhead structure that is 20 m (66 ft) or so above the bottom, however, is not a place for anybody with a fear of heights. This method has been a standard access method for conducting inspections and repairs to vessels for many years. The components are better designed and lighter in weight than ten or more years ago. Therefore, it is more easily constructed today.

5.1.2.2 Portable Staging—This method consists of a platform of sufficient size to carry at least one person. It also includes a winch that is attached to the platform. The wire on the winch is connected to the underdeck structure so that the platform raises towards the wire’s connection point at the underdeck. The size of the platform varies. Some are sized to lift only one person while others are sized to lift up to four or five persons. In fact, some platforms are similar to those used by window washers—lightweight and breakdown for portability. For industrial applications, the staging is built more rugged.
than typically used for window washers, such that the design load is higher. Persons on the staging should have individual safety harnesses attached to them. The Occupational Safety and Health Administration (OSHA) has become more active in verifying contractors perform their work in a safe manner. One high-risk aspect of using this staging is attaching the lifting wires to the overhead. This normally is accomplished by a person walking the deckhead. This person uses a set of stirrups each attached to one end of a short length of wire with some type of hook at the opposite end. The hooks fasten into the deckhead structure, then a person proceeds to walk across the deckhead while moving the stirrups and connecting the platform’s lifting wires to the deckhead. OSHA has become more aware of this activity due to fatalities. They now require these persons to wear safety harnesses connected to lifelines. An alternate method of attaching the lifting wires to the overhead, but not normally used, is by drilling holes into the deck and passing wires through them. The wire end is then secured to provide a holding point. The problem is that drilling holes into a deck is not a desired situation. It can become a source of future fracture problems if not properly done and might be located in an area of high stress.

5.1.2.3 Rafting—This is a straightforward system and may be the easiest to understand. It consists simply of rowing around in a rubber raft while the water level in the tank is changed in height. This method has been used for many years, not only for inspection reasons, but also for access to upper regions of a tank by the vessel’s crew for conducting repairs. In fact, there are various objects that can be used to provide buoyancy when access to high areas in a tank is needed and a rubber raft is not available. For structural inspections, normally two persons occupy a raft; this enhances the raft’s maneuverability and the inspection. All areas of the structure can be accessed easily from the level of the liquid. Vessels with deep transverse structures, however, prohibit safely accessing the deckhead structure. If the water rises, it traps the raft’s occupants between the structure and water level without a safe exit from the tank. This applies to any tank with a deckhead structure to some degree. An important aspect of this method relating to the thoroughness of an inspection is the rate of water level change. If the intervals are too great, such as 5 m (16.5 ft), relating to the thoroughness of an inspection is the rate of water structure to some degree. An important aspect of this method exit from the tank. This applies to any tank with a deckhead occupying between the structure and water level without a safe transverse structures, however, prohibit safely accessing the platform’s lifting wires to the deckhead. OSHA has become more aware of this activity due to fatalities. They now require these persons to wear safety harnesses connected to lifelines. An alternate method of attaching the lifting wires to the overhead, but not normally used, is by drilling holes into the deck and passing wires through them. The wire end is then secured to provide a holding point. The problem is that drilling holes into a deck is not a desired situation. It can become a source of future fracture problems if not properly done and might be located in an area of high stress.

5.1.2.4 Climbing—This method often complements one of the other methods mentioned in the preceding sections. It varies from climbing the structure a short distance to see a particular location better, to climbing the height of the tank with the aid of a safety harness. The latter, although demonstrated, is not typically used. There are hazards when climbing any height; the higher one goes, the greater the risk of severe injury if one falls. Prudent judgment, therefore, is necessary to prevent accidents. This includes a decision to not climb to any height if the circumstances so indicate, for example, slippery conditions, physical problems, and so forth.

5.1.2.5 Other—The inspection methods here are not considered to be primary methods but rather ones that can support and enhance one or more of the methods previously described. They serve a specific purpose.

5.1.2.6 Ziggy—This mechanical device consists of a mechanism positioned above the deck that raises and lowers, and rotates from side to side, with a steel column constructed of short, rectangular tubes. The tubes are lowered through a butterworth hole to the bottom. A horizontal beam is attached to the bottom end of the column, and a single-person basket is attached to the other end of the beam. As the column is raised or lowered, the person in the basket can extend oneself to a distance between 3 and 9 m (10 and 30 ft) from the vertical column. This device permits one to inspect the side and underdeck structure without building a tower of staging, climbing the side shell, or filling the tank with water to the underdeck. It can be operated from the basket or from the deck positions.

5.1.2.7 Remote Operating Vehicle (ROV)—An ROV is similar to a miniature underwater, unmanned vehicle. This method also requires filling the tank with water. Unlike the rafting method, however, it is important to fill the tank as close to 100 % as possible. The ROV typically is sphere-like and has small, external propellers running inside ducts for maneuvering. They all include a camera. Some models are capable of doing additional operations other than viewing the tank internals, such as thickness gaging, cleaning off the surface, and varying the light intensity. An operator controls the ROV outside the tank at a control console. There is a monitor alongside to follow the maneuvers and to view the structure. A video tape of the whole inspection or parts thereof can be made. The communication link between the control panel and ROV is by cables connecting the two. It is important, therefore, to understand the compartment size and extent of inspection expected by the unit. The operator must understand the tank space where the ROV is operating. A knowledge of the internals, protruding obstacles, pipelines, and tank boundaries, therefore, is necessary to prevent the unit from becoming tangled in them.

5.1.2.8 Maricam—This unit could be considered a hybrid of the ROV and Ziggy methods. It consists of a high-resolution video camera mounted on a vertical column extended into the tank space from the deck. It too is remotely operated by two persons on deck who control the camera’s movement, the light intensity, the lens’ iris, zoom, and focus features; document suspect areas by video taping or manually logging the data; and monitor the video screen.

5.1.3 Identification of Telltale Areas in a Marine Vessel’s Structure:

5.1.4 Determination of standard tolerances and acceptable levels for structural deviations on the basis of how they affect the structural performance as agreed upon by the owner, classification society, flag state, and shipyard

5.1.5 Selection of a corrosion protection system, such as coatings and cathodic protection, that will best protect the structure for the intended service under the maintenance plan. The selection of coatings should consider, in addition to
protecting the structure, the ability to properly inspect the structure after a period of service.

5.2 **Inspectability**—In addition to the considerations of inspection methods in 5.1.1, the following precautions should be taken during design and preparation of detailed structural drawings:

5.2.1 Provide appropriate transverse and longitudinal member spacings and member depths to facilitate safe access.

5.2.2 Avoid blind spots in the structural arrangements.

5.2.3 Provide access plates or holes for entering tightly arranged structures. In addition to providing minimum sizes for openings, other considerations such as footholds, escape routes, alignment, and means of ventilation should be considered. In large tanks, catwalks should be considered in order to reduce the need for constructing staging for inspections. Resolution A.272(VIII), as amended by A.330(IX) gives specific details for accessways for inspection.

5.2.4 Coordinating the selection of coating systems with the type of inspection program for the vessel. If removal of coatings will be necessary for random visual inspections, an acceptable program should be established in advance with the flag state and classification society.

5.2.5 Providing access to structural items subject to periodic in-service inspections, such as installing permanent rungs to facilitate access to otherwise uninspectable areas. These precautions could preclude the necessity of installing costly staging during in-service inspections.

5.2.6 The main objective is to ensure that structural design facilitates in-service and shipyard inspections. Toward this goal, a thorough review of structural design drawings to ensure proper consideration was given for structural inspections, which should be accomplished prior to structural fabrication.

5.2.7 Use of structural members that facilitate proper application of coating, such as bulb flats or flat bars, where access for coating application and corrosion removal is limited.

5.3 **Inspection Plan**—An inspection plan should be prepared for the vessel under design on the basis of analyses and investigations performed during the design stages. The plan should:

5.3.1 Provide accessibility instructions for parts to be inspected.

5.3.2 Identify telltale areas that should receive special attention during inspection activities. A separate set of plans should be included to identify these telltale areas. Specific inspection requirements should be given. NVIC 15-91 includes in its enclosures (2) and (3) a breakdown of necessary information to document these telltale areas (referred to in this guide as “critical areas”).

5.3.3 Include a listing of all structural elements to be inspected, as well as the type and extent of inspections for each. A typical summary checklist for primary strength members is given in Table 1. This list should be expanded to cover all primary, secondary, and structural details, as applicable, to the specific vessel to be constructed.

5.3.4 Upon contract signing with a shipyard, the designer should list or reference the applicable standard used to develop structural tolerances and acceptable levels of deviation from these standards. The levels adopted should either be one of existing compilations or a modification of one suitable for use in negotiations with the prospective builders prior to signing a construction contract.

5.4 Guidance on standard tolerances and acceptable deviations can be obtained from classification society Rules, IHI SPAIS, Production Standards of the German Shipbuilding Industry, VIS 530 or SSC 213 (3, 4, 5, 6), as well as Guide F 1053/F 1053M. Most of these publications also contain recommended repair and corrective action procedures for major deviations from acceptable levels. These recommendations may be used as a baseline in determining the specific corrective action procedures to be adopted for the specific ship to be constructed.

---

4 The boldface numbers in parentheses refer to the list of references at the end of this standard.
6. Inspection Activities During Construction

6.1 By specifying preplanned inspections in excess of what is necessary to ensure structural integrity of the completed vessel, a burden is imposed on the shipyards, and therefore, results in costs and delays to the owners. On the other hand, by specifying and then conducting an insufficient amount of inspection, some deficiencies in the structure may remain undetected and may result in added repair or renewal operations. Accordingly, agreement is needed on a reasonably balanced level of inspection among the parties concerned (shipowner, shipyard, classification society, flag state, and designer). The aforementioned inspection plan can serve as the vehicle for this agreement.

6.2 Owner’s Needs:

6.2.1 The owner of a vessel may need or desire to have conducted certain inspection activities and corrective measures that the shipyard may consider unnecessary or unwarranted from a structural strength viewpoint. An example is the desire of the owner of a high speed container ship to have all surface imperfections on the exterior hull plating, such as burrs, scars, spatter, removed even though these do not affect the ship’s structural integrity and could be considered as cosmetic repair. Such removal, however, is important to the shipowner in light of operational efficiency.

6.2.2 The owner also may have a preference for the type and extent of nondestructive examinations (NDE) to be employed in construction inspections in excess of that required by class or flag state requirements. In such instances, this preference must be clearly stated in the specification.

6.2.3 All the needs expressed by the owner should be discussed by the concerned parties and agreed-upon procedures made a part of the construction inspection plan.

6.3 Receipt Inspection of Materials:

6.3.1 Consideration should be given to the inspection of structural material upon arrival at the shipyard’s receiving area. Discussion with the class society, flag state authorities, the designer, and the shipyard should be conducted in order to determine any such inspection necessary, in addition to their requirements. Material certificates should always be confirmed with the material at delivery. Quality system procedures, in effect, may preclude intensive inspection with activity and record monitoring sufficing. During inspection of material, however, the following defects are those which must be spotted:

- Deviations from nominal dimensions.
- Surface defects, such as excessive pitting and flaking on plate and shape materials.
- Laminations on plates.
- Deviations from the specified type or grade of structural materials.

6.3.2 In order to detect these defects, visual inspections should be made and complemented by measurements for dimensional accuracy and by ultrasonic examinations to detect laminations as necessary. The extent of such examinations must be based on experience. In the last case, a review of mill certification for the plate is necessary.

6.3.3 Recommended tolerance standards and repair procedures for defects in excess of allowable levels are contained in Guide F 1053/F 1053M, SSC 273, and JSOS–Hull Part (7, 8). Repair procedures or acceptance criteria, or both, should be developed with classification society and flag state concurrence.

6.3.4 By reviewing these references, the minimum receipt inspection requirements should be established and included in the ship’s construction inspection program.

6.4 Construction Inspections:

6.4.1 In-process inspections should be performed by the shipyard production department supervisors as a self-inspection activity and by the quality assurance department inspectors for the purpose of assuring adequate control of quality during the ship construction process. The ship’s construction inspection program also should include notations as to the elements of construction required to be inspected by flag state and classification society representatives.

6.4.2 The specified procedures, methods, and organizational roles may vary depending on the shipyard where the construction will take place and on the type and size of the vessel to be constructed. In any case, however, particular visual inspection functions should be accomplished during specific stages of construction.

6.4.3 Visual inspections during subassembly, assembly, and erection stages shall examine carefully the structure with specific attention to the following:

6.4.3.1 Completeness—To make sure that all of the major structural and production members on the subassembly/assembly/module/ship are in place as required by the detail design drawing or in accordance with good marine practice if all areas are not addressed in the drawings.

6.4.3.2 Materials Used—To verify that only the correct materials as specified by the detail design drawings are used. Material identification color codes or markings can be used for this verification.

6.4.3.3 Accuracy—To pinpoint apparent deviations from specified dimensions with the purpose of assuring that subassemblies and assemblies fit together. A preplanned dimensional program is necessary with the purpose of assuring that subassemblies and assemblies fit together. A preplanned dimensional verification program is necessary to accomplish this.

6.4.3.4 Joint Preparation—To ensure accuracy in fit-up, root openings, alignment of members, cleanliness, removal of slag, beveling, and so forth.

6.4.3.5 Weld Layout—This layout is used to determine that weld sizes are correct and that continuous or intermittent welds, or both, are being used in accordance with the detail design drawings. Full penetration welds should be inspected from both sides.

6.4.3.6 Fairness—To observe any noticeably excessive unfairness in the completed unit for the purpose of requiring fairness measurements if necessary.

6.4.3.7 Structural Details—To verify compliance with design drawings of structural details such as clearance cutouts, collars, brackets, stiffener end connections, and so forth.

6.4.3.8 Supports/Braces—To verify that an adequate quantity and quality of supports, braces, and lifting pads are provided and properly located for use in moving and handling
the unit without damaging it or disturbing it, or both, to the point that alignment requirements are exceeded.

6.4.3.9 General Workmanship—To see that the completed structural unit is free of discontinuities, undercuts, weld pockets, sharp ragged edges, nicks, or other damage that may initiate or propagate cracks. To verify that all temporary fabrication/erection attachments that are not required during later stages of construction are properly removed if desired by the owner.

6.4.4 Detailed structural drawings, construction specifications, and the inspection plan prepared during the design process are the specific guidelines for use in judging the acceptability of structures on the basis of visual inspections. A lot depends on the knowledge and experience of the inspector. Whenever the inspector is in doubt as to the acceptability of any part of the inspection criterion, the inspector should refer to the standard tolerances and acceptable deviations contained in SSC 273, JSQS–Hull Part (7, 8), Guide F 1053/F 1053M, or IHI SPAIS (3), the specification or those that may be included in the ship’s inspection plan. If the inspector considers it necessary to have physical measurements or NDE made, the inspector should request them.

6.4.5 Dimensional accuracy and dimensional control activities should cover all stages of construction from mold loft to launching.

6.4.5.1 Mold Loft—Loft sheets, roll molds, furnace molds, and battens should be inspected for dimensional conformance and for completeness of detail with the latest revised detailed structural drawings. Steel tapes used in layouts and measurements should be inspected periodically for accuracy.

6.4.5.2 Plate Shop and Numerically Controlled Burning Area—In order to verify conformance with detailed structural plans, the following should be inspected during plate preparation:

1. Orientation of plate with respect to the molded line.
2. Center punching of frames, buttocks, and waterlines for dimensional accuracy. The centerline of the ship should be used as a master reference line.
3. Spacings and angularities of structural members.
4. Verification of a sufficient final cut allowance.
5. Bevels and collars, final dimensions, alignment, and fairness, after the final cut.

6.4.5.3 Subassembly/Assembly/Erection Areas—The following dimensional accuracy inspections should be accomplished during panel and subassembly fabrication, assembly/unit/module construction, and erection processes in platen areas, pre-outfitting areas, and in building basins or shipways:

1. Orientation of plate with regard to the molded lines.
2. Spacing and dimensions of frames, stiffeners, girders, headers, and so forth.
3. Alignment and fairness, conformance of welds with detail plans and specifications.
4. Squareness and distortion.
5. Ship’s principal dimensions (length, beam, depth).
6. Declivity and straightness of keel.

6.4.6 Alignment and Fairness—Excessive misalignment in structures may cause stress concentrations and, therefore, may lead to failure. Accordingly, alignment inspections should be made during all stages of construction and any excessive, that is, beyond acceptable levels, deviations should be noted, recorded, and reported for research as to its root cause, so that appropriate corrective measures can be taken.

6.4.6.1 Essentially, the alignment measurements for plate edges and structural shapes should be made, after welding, on the following:

1. Shell assemblies, including transverse and longitudinal framing and floors.
2. Longitudinal and transverse bulkhead assemblies.
4. Secondary structures, such as foundation, masts, rudders, tanks, trunks, and so forth.

6.4.6.2 Standard tolerances and acceptable levels for misalignment of various structural members are contained in SSC 273, JSQS–Hull Part, IHI SPAIS (3, 7, 8), or Guide F 1053/F 1053M.

6.4.6.3 The fairness of the plating, frames, beams, stiffeners, etc., should be checked and maintained within acceptable tolerances. Any unfairness found to be permissible should result in a generally fair curve across the plating panel or other structural members.

6.4.7 Weld Inspections—Weld inspections consist of visual surveys, physical measurements, and nondestructive examinations. Weld inspections should be performed no sooner than 24 h after the weld is completed and cool.

6.4.7.1 Weld inspections should be performed in the as-welded condition of the structure, that is, before coating. The weld to be inspected should be clean and all slag should be removed. Simple tools, such as a ruler, throat gage, undercut gage, or a fillet leg gage should be used in measurements to support visual examinations.

6.4.7.2 Tolerance standards and maximum levels of acceptability for welding defects shown as follows are contained, as are all other structural standards, in SSC 273, JSQS–Hull Part, IHI SPAIS (3, 7, 8), American Welding Society references, and classification society documents.

6.4.7.3 Methods, procedures, evaluation, and other requirements for NDE are provided by AWS, SSC–213, ABS (6, 9), and others.

6.4.7.4 Visual inspections and NDE examinations should be directed toward the detection of the following possible weld defects or deficiencies:

1. Errors in weld size per drawings.
2. Lack of fusion (NDE).
3. Undercuts.
4. Deviations from weld contour.
5. Fissures, cracks, or crack-like indications (NDE).
6. Porosity, NDE as well as visually.
7. Failure to wrap around fillet welds.
8. Visible evidence of arc strikes.
9. Sharp or ragged edges.
10. Excessive slag.
11. Slugged welds.
12. Incomplete welds.

6.4.8 NDE—NDEs should be performed according to the building specifications (detailed in the design inspection plan and as contained in the construction inspection program), and
the accompanying field sketches agreed upon by the shipowners, shipyard, and classification society surveyors.

6.4.9 Final Structural Surveys and Tightness Tests—Final structural surveys should be accomplished prior to completion of any unit, module, or the complete erection on the shipway. For all in-process inspections, but specifically for the joint final structural surveys, the preparation of the structure for inspection is very important.

6.4.9.1 During the final structural survey, all the structures should be inspected visually for completeness of all work, including attachments, penetrations, and all permanent access fittings and closures.

6.4.9.2 Tanks, compartments, cofferdams, and void spaces should be tested for tightness to prevent the spreading of flooding, fire, and gases. Tightness checks can be accomplished by means of hose tests, air pressure tests, hydrostatic tests, vacuum box tests, or weld boundary pressure tests. Tests should be carried out in accordance with a compartment testing diagram to be prepared by the shipyard’s engineering department.

6.4.10 Inspection by Classification Societies and Flag State Representatives—These inspections ensure the vessel’s structural integrity and its compliance with the rules and regulations from the standpoint of meeting minimum requirements.

6.4.10.1 Classification societies conduct their own inspections by resident surveyors during the vessel’s construction period. At the end of the construction period, resident surveyors prepare and submit a surveyor report, which is used as one of the inputs for classification society decisions relating to acceptability of the vessel for classification.

6.4.10.2 Flag states also conduct inspections of marine vessels intended to operate under their registration during construction to ensure compliance with the applicable regulations. At the end of the inspection, a file is prepared containing some of the initial plans and design calculations, which also are used in decisions later in the life of the vessel.

6.5 Common Structural Deficiencies:

6.5.1 Many shipyards already have in-house publications for use in identifying most frequently encountered structural deficiencies and recommended corrective measures. Publicly available documents also exist for this purpose. Some of the references that contain common deficiencies, standard tolerances, and standard corrective measures are Guide F 1053/F 1053M, SSC 273, JSQS–Hull Part, IHI SPAIS, Production Standards of the German Shipbuilding Industry, and VIS–530 (3, 4, 5, 7, 8).

6.5.2 Some commonly encountered structural deficiencies are illustrated in Figs. 2–11, which should assist inspectors in identifying them during surveys:

6.5.2.1 Misalignment, Figs. 2 and 3.
6.5.2.2 Excessive gap between members, Fig. 4.
6.5.2.3 Stiffener tilt, Fig. 5.
6.5.2.4 Improper distance between adjacent welds, Figs. 6–8.
6.5.2.5 Weld flaws.
6.5.2.6 Weld undercut.
6.5.2.7 Distortion, Figs. 9 and 10.
6.5.2.8 Deformation of plate, Fig. 11.

6.5.2.9 Cracks, dents, creases, and other damage.

6.6 Recording/Reporting/Evaluation Procedures:

6.6.1 Appropriate forms should be developed or adopted from similar forms used by others for requesting, recording, reporting (corrective action), analyzing, and processing structural inspections, and NDE. Caution should be used as forms developed and used by one shipyard may be different from those used by others, reflecting differences in the quality control organization. These forms should include the following information: record the inspection results, did the condition meet the specification, and, if not, what must be done to correct the situation, including requested assistance from outside bidders.

6.6.2 Dissemination of Inspection Results:

6.6.2.1 Findings from inspection activities, as they relate to specific parts of the ship’s structure, should be recorded on appropriate forms and maintained in the owner’s, ship’s, shipyard’s, or class society’s inspection file. Applicable forms should be distributed to the proper departments in the shipyard, to the owner’s representatives, and to classification society surveyors for review and execution or approval of the recommended corrective action. Each of these is a separate activity, but all in support of the owner.

6.6.2.2 Most important is the feedback of inspection results to the structural designer. By being aware of the deficiencies found and the corrective actions accomplished on the structure,
the designer can analyze the causes and consequences of the deficiency, decide whether the corrective action was sufficient, and determine if the original design should be modified to prevent recurrence of similar deficiencies in follow-on constructions. If such information is proprietary to the owner, the owner should provide such information to the designer.

6.6.2.3 Maintaining brief but clear records of all structural deficiencies and repairs will enable the shipyard to determine the as-built condition of the marine vessel’s structure.

6.7 A thorough review and analysis of all structural inspection reports and deficiency/corrective action records will enable the shipyard to prepare a structural history of the ship’s construction and the condition of its structure as built. This information should be compiled into a complete “Structure Condition Record” for use as a reference basis throughout the ship’s service life. It should record:
6.7.1 All inspected structure found to be within acceptable tolerances. 
6.7.2 The actual accepted tolerances, or deviations from standard, for the structures. 
6.7.3 Structure found to have deviations larger than allowable levels, but jointly accepted by yard, owner, classification society, and flag state inspectors as not requiring corrective action. 
6.7.4 The extent of actual deviations for these structures or structural elements. Structures found to have unacceptable deviations but repaired using standard corrective action procedures. 
6.7.5 Structure found to have unacceptably large deviations for which the original design had to be modified to avoid recurrences of deficiencies. 

7. Preparation of In-Service Inspection Program 
7.1 At the end of a ship’s construction period, the “Design Inspection Plan,” the “Construction Inspection Program,” and the “Structure Condition Record” should be prepared for structural inspections to be performed during the vessel’s operating life. This guide should reconcile the three aforementioned documents and include the following: 
7.1.1 Identification of telltale areas as determined in the “Design Inspection Plan.” 
7.1.2 Any changes to telltale areas due to built-in material deficiencies or accepted fabrication errors during the construction process. 
7.1.3 Other significant areas for inspection, not due to design allowance, but due solely to material or fabrication errors, or both, during construction. 
7.1.4 Prepare an inspection checklist based on the preceding considerations identifying all structures to be subjected to in-service inspections. The inspection checklist should include: 
7.1.4.1 Inspection frequencies. 
7.1.4.2 Methods and procedures for inspections. 
7.1.4.3 Tools and equipment to be used. 
7.1.4.4 Responsibilities for performance of inspections, that is, whether to be conducted by the owner’s representatives
while vessel is in service, by a shipyard crew while afloat, or by the yard crew during drydocking, and so forth.

7.1.4.5 Cargo to be carried.
7.1.4.6 Marine vessel’s service.
7.1.4.7 History of prior in-service inspections.

7.2 In-Service Inspections:

7.2.1 General:

7.2.1.1 The condition of the ship’s structure should be kept under constant surveillance by situational and periodical inspections throughout its operating life in accordance with an in-service inspection program. This plan is prepared during final stages of the construction period and should take into account necessary flag state- and classification-society required inspection and surveys.

7.2.1.2 Structural inspections conducted between those required by the flag state or classification society must be based on decisions by the owner, and it is his responsibility to provide trained personnel to conduct the inspections while the vessel is in service. Some periodic inspections may be performed by the crew, but some would require preparations or training beyond normally expected crew capabilities.

7.2.1.3 The in-service inspection program prepared during the construction period should include, among other things, the identified telltale areas for which the owner’s representatives should perform interim inspections. The program also should have flagged those structures that are considered significant due to design features or fabrication history, that is, built-in material/fabrication/workmanship variations.

7.2.1.4 The in-service inspection program should be updated during the vessel’s life to reflect the extent of coatings breakdown, service in which the vessel is operated, and how the structure has withstood that service. As problems develop during the life of the vessel, standard repair procedures for recurring problems should be developed and entered into the inspection program for the specific details. In subsequent inspections, these repairs should be inspected to verify that they have solved the preexisting problem. Repair procedures should be developed with classification society and flag state concurrence.

7.2.2 Owner’s Representatives Inspection:

7.2.2.1 In general, owner’s representatives will have some opportunity to inspect the structure while at sea. These inspections may reveal deterioration or damage to parts of the structure that may be repaired by the crew, riding maintenance persons, or if more detailed inspection and repair is needed, possibly in a shipyard. In some cases, parts of the ship’s structure may be uninspectable while at sea because the structure may be inaccessible due to existence of fuel, water, cargo, insulation, and so forth, in the spaces to be inspected. In this case, the owner should plan ahead for yard inspections.

7.2.2.2 Owner representatives’ inspections, when possible, can accomplish the following:

(1) Detect and repair minor damage and deterioration.
(2) Obtain an early warning of major structural problems.
(3) Keep corrosion control systems under surveillance.
(4) Identify areas for detailed surveys and plan and budget for shipyard availability.

(5) By doing all of the preceding, reduce overall survey and repair costs.

7.2.2.3 Some of the typical structural flaws that the owner’s representatives can detect are:

(1) Scale formation on plates and shapes.
(2) Pitting.
(3) Localized wastage.
(4) Resultant loss of thickness.
(5) Wastage of zinc anodes in tanks, if used.
(6) Poor condition of coatings.
(7) Buckling in structural members.
(8) Fractures, cracks.
(9) Other obvious damage, such as dents, creases, and so forth.

7.2.2.4 In addition to main structural elements, inspections also should cover miscellaneous structures, such as handrails, ladders, platforms, valve reach rods, and so forth.

7.2.2.5 Enhanced surveys of main structural members inspected by the owner’s representatives with the concurrence of the class society, to the extent possible, should include deck plating, underdeck girders and longitudinals, side shell plating and framing, transverse and longitudinal bulkheads with their stiffeners, and stringer platforms, if any, as well as other areas of concern as determined by IMO, IACS, or the particular class society or flag state.

7.2.2.6 Figs. 11-22 show some typical structural deficiencies, such as, fractures, buckling, and deterioration, that can be detected by owner representative’s inspections. These sketches are applicable to the design of a tanker. Similar sketches should be developed for the specific ship to be inspected and included in the in-service inspection program. The Tanker Structure Cooperative Form Guidance Manuals (10) are especially good sources for graphical representations.

7.2.3 Periodic Inspection by Classification Societies and Port and Flag State Representatives—These bodies conduct inspections of the marine vessel’s structure in accordance with well-established procedures requirements. It is the owner’s
responsibility to ensure the vessel is properly maintained. Sole reliance on these bodies’ minimum periodic inspections is not judicial. Typical procedures and frequencies are described in detail in the classification society rules as applicable to vessels of varying types and by flag state requirements.

7.2.4 Repair and Conversion Inspections:

7.2.4.1 The procedures to be followed in performing structural inspection for and during major repairs and overhaul availabilities, essentially, are combinations of construction and in-service inspection procedures. The repairs to any structure due to damage or deterioration should follow established repair procedures contained in the in-service inspection program. Whenever the damage is so extensive that removal of the existing structure and renewal with new materials is required, the construction inspection program requirements should be observed.

7.2.4.2 When alterations are to be made to the existing structure as necessitated by a conversion design, the areas to be modified should be structurally inspected in accordance with
in-service inspection requirements. The newly constructed parts or additional structures should be inspected in accordance with new construction requirements.

7.2.4.3 Special attention should be given to the continuity and compatibility of structures and materials for major structural renewals and for structural modifications or additions, or both.

7.2.5 Maintaining and Updating the Structure Condition Record:

7.2.5.1 The Structure Condition Record (SCR) prepared at the end of the construction period should be referred to before initiating periodic in-service inspection activities, even if the specific requirements from it have already been incorporated into an In-Service Inspection Program. The SCR should have descriptive background information to enable structural inspectors to understand better the reasons for special inspection requirements for the specific parts of the structure.

7.2.5.2 The SCR should be kept current by modifying the existing data or by adding new data, as applicable, from the results of any in-service inspections or any corrective measures, or both, taken on the basis thereof.

1. Scope

1.1 This specification provides the requirements for design, construction, performance, and testing of solid state bargraph-type indicating meters.

1.2 The solid state bargraph meters covered by this specification are intended for use in shipboard applications of electrical measurement. This specification covers the requirements and quality assurance provisions for solid state, panel-type (edgewise), and rectangular switchboard-type instruments, which use light-emitting diodes (LEDs) for bargraph indication and optional digital displays.

1.3 This specification’s requirements may be invoked for specialized measurement applications where another quantity, for example, position, weight, concentration of a trace element in an atmosphere sample, and so forth, is converted to electrical energy for display and measurement. Special dial markings shall be specified for such cases.

1.4 The values stated in metric units are to be regarded as the standard. The values given in parentheses are for information only.

2. Referenced Documents

2.1 ASTM Standards:
B 117 Practice for Operating Salt Spray (Fog) Apparatus
D 3951 Practice for Commercial Packaging
F 1166 Practice for Human Engineering Design for Marine Systems, Equipment and Facilities

2.2 Federal Specifications:
TT–E–529 Enamel, Alkyd, Semigloss, Low VOC Content

2.3 Federal Standards:
H28 Screw Thread Standards for Federal Services

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 accuracy, \( n \)—the accuracy is a number that defines the limit of errors expressed as a percentage of full-scale value.

3.1.2 center-zero meter, \( n \)—meter with display mode characterized by a sequentially illuminated string of LEDs starting at the center scale zero position and extending in either direction from zero, proportional to the polarity and magnitude of the input signal.

3.1.3 dual bargraph display, \( n \)—two completely independent bargraph displays included in a single enclosure.

3.1.4 end-scale value, \( n \)—the value of the actuating electrical quantity that corresponds to end scale indication. When zero is not at the end or at the electrical center of the scale, the higher value is used. See Table 1.

3.1.5 end-zero meter, \( n \)—meter with display mode characterized by a sequentially illuminated string of LEDs starting from a zero point, normally at the left for switchboard-style meters or horizontally installed edgewise meters, or the bottom of vertically installed edgewise meters, that extends in the direction of full-scale value.

3.1.6 full-scale value, \( n \)—full-scale value is the largest value of the actuating electrical quantity, which can be indicated on the scale. For instruments with zero between the ends of the scale, the full-scale value is the arithmetic sum of the values of the actuating electrical quantity corresponding to the two ends of the scale.

3.1.7 response time, \( n \)—the response time is the time required for the indicating means to display a new value after a step change has occurred in the measured quantity to a new constant value.

3.1.8 scale division, \( n \)—a scale division is the increment between the centers of two consecutive scale marks. The number of scale marks is one more than the number of scale divisions. For example, 10 scale divisions require 11 scale marks.

3.1.8.1 linear scale divisions, \( n \)—linear scale divisions are scale divisions that are spaced an equal distance apart and of the same value, for example, scale divisions spaced 5 \text{A} apart on a 100–A meter.

3.1.8.2 nonlinear scale divisions, \( n \)—nonlinear scale divisions are scale divisions of the same value spaced an unequal distance apart.

3.1.9 scale length, \( n \)—the scale length is the length of the path described by the pattern of the LEDs in moving from one end of the scale to the other. For multiple scale meters, the longest scale shall be used to determine the scale length.

3.1.10 scale visibility, \( n \)—scale visibility is the maximum horizontal or vertical viewing angle measured from a line normal to the scale from which all scale marks and arcs, but not necessarily all markings, may be seen.

4. Classification

4.1 Classification—Bargraph meters covered in this specification shall be classified by type and style as specified in 4.2-4.3.

4.2 Type—The type designation defines the physical configuration of the meter and the scale.

4.2.1 Rectangular/switchboard-type meters present angular displays from 90 to 270° scale for the measured parameter(s). Fig. 1 provides typical dimensional and mounting data for rectangular/switchboard-type meters.

4.2.2 Edgewise/panel-type meters present linear displays for measured parameters. Fig. 2 provides typical dimensional and mounting data for edgewise type meters.

4.2.2.1 Orientation of Meter—For edgewise/panel-type meters, the scale marking shall be specified either for a vertical or horizontal mounting condition.

4.3 Style—The style designation defines the meters display attributes as follows:

4.3.1 Bargraph Display—The bargraph display shall consist of light-emitting diode (LED) elements that illuminate to produce a bar image proportional to the input signal. The display designation defines whether the meter has single or dual bargraph displays.

4.3.2 Digital Display—The digital display designation defines the number of digits in the digital display as follows:

4.3.2.1 3-digit display.
4.3.2.2 3½-digit display.
4.3.2.3 4-digit display.
4.3.2.4 4½-digit display
4.3.2.5 No digital display.

5. Ordering Information

5.1 Purchase orders or inquiries for bargraph meters of this specification shall specify the following:
5.1.1 Title, date, and year of this specification.
5.1.2 Quantity.
5.1.3 Type and for edgewise meter, the orientation (see 4.2).
5.1.4 Style of display (single or dual, digital display) (see 4.3).
5.1.5 Window type (plastic or shatterproof glass) (see 7.5).
5.1.6 Dial colors (see 7.9.1.1).
5.1.7 Range(s) (see 7.9.2).
5.1.8 Power supply voltage (see 8.1.1).
5.1.9 Signal input (analog or digital) (see 8.1.2).
5.1.10 Color(s) of bargraph display (see 8.2.2).
5.1.11 Optional features available:

5.1.11.1 Anti-glare windows (see 7.5.1).
5.1.11.2 Splashproof or spraytight window (see 7.5.2).
5.1.11.3 Internal illumination (see 7.6).
5.1.11.4 External accessories (see 7.8).
5.1.11.5 Alarm set points (see 8.1.4).
5.1.11.6 Digital display:
5.1.11.7 Nonstandard range values (see 8.2.4).
5.1.11.8 Dot matrix display types (see 8.2.4).
5.1.11.9 Intensity control (see 8.2.5).
5.1.12 Certification requirements (See 10).
5.1.13 Packaging requirements.
5.1.14 Testing requirements (include only if tests other than the production tests required by this specification are to be performed).

6. Materials and Manufacture

6.1 Materials—All materials used in the construction of these bargraph meters shall be of a quality suitable for the purpose intended and shall conform to the requirements of this specification.

6.1.1 Metals—Metals and the treatment of metals shall be corrosion-resistant.

6.1.2 Plastics—Plastic, when used, shall be suitable thermoplastic or thermosetting material so molded as to produce a dense solid structure, uniform in texture, finish, and mechanical properties.

6.1.3 Glass—Glass used for the meter window shall be the shatterproof type.

6.1.4 Gaskets—Material used in gaskets shall not cause corrosion of metal parts with which they come in contact.

6.2 Manufacture:

6.2.1 Finishes:

6.2.1.1 External Finishes—The portion of the meter case exposed to view from the front of the panel or switchboard shall have a black semigloss finish. No nickel or bright trimmings shall be used. The external finish may be epoxy-coated, electro-coated, or painted in accordance with TT–E–529. Metal cases shall be rendered resistant to corrosion prior to the application of the final finish.

6.2.1.2 Internal Finishes—Internal finishes shall be of a material that shall not melt, crack, chip, blister, or scale as a result of the tests specified herein.

6.3 Threaded Parts—Threaded parts shall be in accordance with FED-STD-H28. Where practical, threads shall be in conformity with the coarse-thread series. The fine-thread series shall be used only for applications that might show a definite advantage through their use. Where a special diameter pitch combination is required, the thread shall be of American National Form and of any pitch between 16 and 36 which is used in the fine-thread series.

6.3.1 Locking of Screw-Thread Assemblies—Screw-thread assemblies shall not loosen as a result of the tests specified herein. When practicable, split-type lockwashers or equivalent means shall be provided under all nuts.

**NOTES:** All dimensions are in millimeters (inches are in parentheses and are nominal unless otherwise specified). For specific drilling information, contact the manufacturer.

**Fig. 2** Dimensional Characteristics of Edgewise Meters
6.4 Sealing—The meter case shall be sealed by means of gaskets, by fusing or soldering metal-to-metal or metal-to-glass, or other means which will enable the meter to withstand the tests specified herein.

7. Design and Construction

7.1 Dimensional Data—Typical physical dimensions for switchboard and edgewise meters are shown in Fig. 1 and Fig. 2.

7.2 Mounting—Bargraph meter shall be front panel mounted to simplify mechanical installation or removal for service, or both. Electrical connections locations shall be designed to facilitate meter removal. Typical mounting dimensions are indicated in Fig. 1 and Fig. 2.

7.2.1 Mounting Hardware—The necessary mounting hardware, such as mounting clips, nuts, washers, bolts, shall be supplied with each meter. The machine screws shall have the same finish as the external finish (see 6.2.1.1).

7.3 Maintainability—The meter shall be constructed so that no special tools are required for insertion or removal of the meter.

7.4 Cases—Cases shall be corrosion resistant. Cases shall be designed and constructed with close-fitting joints to minimize the entrance of dust and moisture (see 6.4).

7.5 Windows—The meter display shall be provided with a window of methyl methacrylate (MMA), polycarbonate (PC), or shatterproof glass. If the window is made MMA or PC, the external surface shall be treated to resist scratching. The window shall be free from detrimental defects that would prevent the display from being easily read or from meeting the luminous distribution and color requirement. Such defects include electrostatic effects, scratches, chips, cracks, or craze.

7.5.1 Anti-Glare Coatings—When anti-glare is specified, windows shall be coated with an anti-glare coating. The coating shall be uniform in quality and condition, clean, smooth, and free from foreign materials. The coating shall show no evidence of flaking, peeling, or blistering. The coating shall not contain blemishes such as discolorations, stains, smears, and streaks. The coating shall show no evidence of a cloudy or hazy appearance.

7.5.1.1 Specular Reflectance—The coating reflectance shall not be greater than 0.6 % for energy incident on the surface at an angle of 0 to 15° inclusive. The reflectance shall be not greater than 1.0 % at an angle of 30°.

7.5.1.2 Light Loss—The coating light loss shall be not greater than 2.0 %.

7.5.2 Splashproof/Spraytight Windows—When specified, splashproof or spraytight windows shall be furnished.

7.6 Internal Illumination—When specified, meters shall be equipped with internal illumination provided by a minimum of two lamps, so placed to illuminate the dial evenly.

7.7 Auxiliary Components—All connections from the shunts and resistors to the input terminals of the meters shall be insulated to prevent shock hazard.

7.8 External Accessories—External shunt, shunt leads, transformers, resistors, and other external accessories shall be furnished when required.

7.9 Meter Scales:

7.9.1 Dial—The dial shall be made of stiff material and shall be supported and secured firmly to the meter.

7.9.1.1 Dial Colors—The meter dial shall have white markings on a black background as standard.

7.9.1.2 Dial Markings—Dial legend markings shall be sharply defined and visible from the front of the case but not distract attention from the scale markings. Unless otherwise specified, the following information shall be marked on the dial or on an attached nameplate.

(a) Manufacturer’s name.

(b) Units of measurement.

(c) The quantity producing end-scale deflection. For end-zero meters, the dial markings shall be FS, indicating full scale, followed by the full-scale value and units of measurement, for example, FS-50 mV. For meters that are not end-zero meters, the dial markings shall be marked ES indicating end scale followed by the end-scale value and units of measurement, for example, ES-50 mV).

7.9.2 Ranges—For end-zero meters, the full-scale ranges shall be as specified. For meters that are not end-zero meters, the center and end-scale ranges shall be specified appropriately.

7.9.3 Scale Divisions—Unless otherwise specified, the value of each scale division shall be one, two, or five of the units measured or any decimal multiple or submultiple of these numbers.

7.9.3.1 Linear Scales—The total number of scale divisions shall be determined by dividing the total range by the smallest increment. For example; a 150-V scale with the smallest increment of 5 V is listed as having 30 scale divisions.

7.9.3.2 Nonlinear Scales—The total number of scale divisions shall be determined by dividing the total range by the smallest increment, although to avoid crowding scale marks, a portion of the scale shall not be marked. For example, a 100-A scale with the smallest increment of 2 A, but with no marks between 0 and 10 A, is listed as having 50 scale divisions.

7.9.4 Scale Visibility—The scale and characters shall be uniform visually in character brightness, legibility, and cleanliness of display with all elements of the meter illuminated. The entire meter scale shall be clearly visible from a distance of 1 m (3 ft) and from a viewing angle of 45° from normal; both vertically and horizontally. The scale visibility shall not deteriorate during the tests specified herein.

7.9.5 Scale Markings—Numerals, letters, and symbols shall be in accordance with Practice F 1166. Scale markings shall be as specified herein.

7.9.5.1 The orientation of numerals shall be tangential or erect for 90° scales, erect for 180 and 270° scaleplates, and erect for edgewise scales.

7.9.5.2 The sequence of scale divisions and numerals through the linear portion of the scale plate shall be uniform.

7.9.5.3 The scales shall begin and end with a numbered mark, including 0, when applicable.

7.9.5.4 There shall be not greater than five minor scale divisions between an intermediate or major scale division nor greater than three intermediate scale divisions between a major scale division.

7.9.5.5 The numbered markings shall be spaced uniformly and shall be expressed in the same units of measurement as
those of the end-scale marking. One, two, and five or decimal multiples thereof, shall be used when possible.

7.9.5.6 Scale division markings shall occupy not greater than 20 % of the space between a scale division mark and an adjacent mark.

8. Requirements

8.1 Electrical Requirements:

8.1.1 Power Supply Voltage—The meters shall operate from a voltage as specified as follows. A means of reverse voltage protection shall be provided:

\[
\begin{align*}
&5 \pm 0.25 \text{ V direct current (Vdc)} \\
&28 \pm 1.0 \text{ Vdc} \\
&115 \pm 8.0 \text{ V alternating current (Vac)}
\end{align*}
\]

8.1.2 Signal Input—The meters shall accept a digital or analog signal as specified.

8.1.3 Insulation Resistance—The insulation resistance shall be not less than 2 M\(\Omega\) between the external terminals and the meter case.

8.1.4 Alarm Set Points—When specified, the meter shall be furnished with adjustable visible set points with form-C relay contact outputs for control of external devices such as remote alarms. The hysteresis of set points shall be not greater than 1.0 % of full scale.

8.1.4.1 Setting—Set points shall be programmed from the front of the meter. Set points should be set to a point on the bargraph as standard and use of the digital display for setting exact numerical values is an option.

8.2 Displays:

8.2.1 Color Coding—The LED color coding shall conform to Practice F 1166.

8.2.2 Bargraph Display—The bargraph display shall consist of segmented LED displays of the colors specified, which illuminate to produce a bar image equal to the corresponding scale value of the input. LED display color selection includes red, green, amber or use of tricolor LED display as an option.

8.2.3 Power-On Indication—The zero LED shall be continuously illuminated to serve as a “power on” and as a “zero reference” even in the absence of a signal input.

8.2.4 Digital Display—When specified, the meter shall include a red LED digital display that shall display continuously a specified range of values. The standard digital display shall match the bargraph display. An optional feature of different range values for the digital and bargraph displays shall be available when specified. The standard nominal character height shall be 4.88 mm (0.192 in.) for edgewise types with 2.4 mm (0.095 in.) as an option. The standard nominal character height shall be 10.5 mm (0.41 in.) for switchboard-type meters. The display type shall be seven segment as standard with dot matrix as an option.

8.2.5 Intensity Control—When specified, dimming controls shall be provided to maintain appropriate brightness, legibility, and operator dark adaptation level. These controls shall apply to all LED displays and, when used, dial illumination. The display luminance value shall vary in direct proportion to ambient lighting, and the dial illumination in inverse proportion.

8.2.6 Adjustments—The meter shall contain provisions to adjust the zero-offset and full-scale range. The adjustment devices shall be accessible from the rear of the meter when connected to the input signal and power supply sources.

8.2.7 Set Point Visual Indication—Visual indication of the set point locations shall be shown on the bargraph display by illuminating that LED segment corresponding to the set value when the input signal is lower than the set point value. When the input signal is greater than the set point value, the LED segment corresponding with the set point value is off. When the signal level is one LED segment greater or lower than the set point value, the LED corresponding to the set point value will flash once a second (1 Hz). When the signal level and the set point value are the same, the LED corresponding to the location will flash twice a second (2 Hz).

8.3 Performance Requirements:

8.3.1 Zero Adjustment—The meter shall include provision for zero adjustment by automatic or manual means. Manual means for zero adjustments shall provide for a minimum excursion of ±1 % of full scale about scale zero. The means shall be designed such that scale zero does not change as a result of any of the tests specified herein.

8.3.2 Span Adjustment—The meter shall include provision for span adjustment that provides for a full-scale adjustment above and below full scale of not less than 1.0 % of the rated full scale. The span adjuster shall be designed to prevent it from shaking loose and changing adjustment when subject to tests specified herein.

8.3.3 Accuracy:

8.3.3.1 Bargraph Display—The required accuracy of the meter bargraph display shall be established using the following equation:

\[
\text{Bargraph display accuracy} = \frac{100}{\text{number of LED elements}} - 1
\]

8.3.3.2 Digital Display Accuracy—The error of the digital display shall be not greater than 1.0 % for 3- and 3½-digit displays and shall be not greater than 0.1 % for displays with 4- and 4½-digit displays.

8.3.4 Response Time—The response time of the meter shall be not greater than 2 s for a zero to full-scale step input or full scale to zero step input signal.

8.3.5 Display Illuminance:

8.3.5.1 Axial Illuminance—The bargraph segment shall have a minimum illuminance of 60 mcd (0.6 mfc) at a distance of 200 mm (3.8 in.).

8.3.5.2 Illuminance Variation—The illuminance variation of the bargraph segments and the digital displays shall be not greater than 2.4 to 1.

8.3.6 Chromaticity—The chromaticity for LEDs shall be as follows:

8.3.6.1 Red shall be standard high efficiency with a dominant wavelength of 626 ± 2 nm.

8.3.6.2 Green shall be standard high efficiency with a dominant wavelength of 574 ± 2 nm.

8.3.6.3 Amber shall be standard high efficiency with a dominant wavelength of 585 ± 2 nm.

8.3.7 Overload—The meter shall be able to withstand a momentary overload of 200 % of full scale. The meter shall withstand a sustained overload of 20 % of full scale. During an overload, the digital display shall indicate the full-scale value
and all LED display elements shall illuminate except the most significant LED element shall flash. The meter shall meet the accuracy requirements of 8.3.3.

8.4 Environmental Requirements:

8.4.1 Temperature—The meter shall operate in an ambient temperature range from 0 to +65°C, and shall withstand, without damage, a nonoperating (storage) temperature range of −55 to +85°C. The temperature error shall be not greater than the accuracy requirements of 8.3.3.

8.4.2 Vibration—The meters shall show no evidence of breakage, permanent deformation, or loosening of parts and shall retain their serviceability. The meter shall meet the accuracy requirements of 8.3.3.

8.4.3 Salt Fog—The meter shall show no evidence of salt penetration into the meter encasement nor evidence of corrosive effects, peeling, flaking, or color change in material.

8.4.4 Temperature-Humidity Cycling—The meter shall show no evidence of deterioration of parts or materials, loosening of finishes, physical distortion, corrosion of metals, moisture entrapment, or separation of bonded surfaces. The meter shall meet the accuracy requirements of 8.3.3.

9. Conformance and Production Tests

9.1 Conformance testing of a random sample may be requested by the purchaser to verify that selected performance characteristics specified in this standard have been incorporated in the meter design and have been maintained in the production bargraph meters supplied. These tests would not normally be performed unless specifically required. Production tests are routine tests performed on production units, or samples thereof, to ensure that basic requirements are met.

9.2 Reference Conditions—Reference conditions for testing meter performance shall be as follows:

9.2.1 Temperature: 23 ± 2°C.

9.2.2 Relative humidity: 40 to 60%.

9.2.3 Atmospheric pressure: 575- to 800-mm mercury.

9.2.4 Position: on vertical panel.

9.2.5 External magnetic field: of the earth’s field only.

9.2.6 Waveform (ac meter only): sinusoidal.

9.2.7 Warm-up time: 30 min.

9.2.8 Frequency (for ac meters other than frequency meters): rated ±3%.

9.2.9 Voltage (for meters other than volunteers): rated value.

9.3 Zero Adjust—Meters shall be set to zero with use of the zero adjuster at the completion of each test.

9.4 Number of Scale Readings—Scale reading shall be taken at approximately six equidistant points on the scale including the end-scale points.

9.5 Calibration—A calibration inspection shall be conducted when specified in the individual test. It consists of applying known values of excitation to the meter, with not less than five equally spaced intervals over the full range of the meter and recording the correspondingly displayed values.

9.6 Conformance Tests:

9.6.1 Accuracy—The accuracy shall be determined for the bargraph and digital displays under reference conditions (see 9.1) as follows:

9.6.1.1 Apply excitation to illuminate the exact end-scale LED mark and record the value of excitation.

9.6.1.2 Within 15 min, reduce the value of excitation to illuminate LEDs of not less than five other approximately equidistant scale marks including the zero mark. Measure and record the value of excitation at each scale mark.

9.6.1.3 The difference between the reference and measured conditions shall be calculated, in percentage of full scale, for each measured point. The accuracy of the meter shall be verified by using the greatest difference, in percentage, that was calculated.

9.6.2 Response Time—A photodetector with known response characteristics, having adequate sensitivity and resolution to respond to one element of the display, shall be positioned at the 80% element of the meter display. The photodetector output shall be monitored with a storage oscilloscope or other suitable means. A signal input not less than 80% of the meter range shall be applied to the meter input in less than 10 ms and held constant. This signal shall also be used to trigger the oscilloscope. Response time required for the display element at 80% to illuminate shall be determined.

9.6.3 Insulation Resistance—The insulation resistance of the meter shall be determined by applying a test voltage (V₁) between the external terminals and the meter case, through a 1000-Ω resistor. The type of current applied (ac or dc) is dependent upon the terminal’s normally applied excitation. The level of V₁ for circuits whose normally applied level is less than 50 V shall be 250 V. The level of V₁ for circuits whose normal excitation is 50 V and higher shall be 10 times the normal excitation or 1000 Vdc (707 V rms), whichever is less. The current flowing through the terminals to ground is determined using the following:

\[ E_M = \frac{V_M}{R_M} \]

where:

- \( E_M \) = Voltage drop across resistor;
- \( R_M \) = Resistance, 1000 Ω; and
- \( I_M \) = Current through terminals to ground.

The insulation resistance can be determined using \( I_M \) in the following equation:

\[ \frac{V_T}{I_M} - 1000 \Omega = IR_M \]

where:

- \( IR_M \) = Insulation resistance of meter.

9.6.4 Display Illuminance—Illuminance shall be measured with instrumentation having a response that is within 2% of the International Commission on Illumination (CIE) photopic curve over the specified color region.

9.6.4.1 Axial Luminance—The illuminance shall be measured with no ambient lighting, with all segments of the meter’s display illuminated. All readings shall be taken to and at a distance of 200 mm from the plane of the front surface of the display elements, centered on the horizontal and vertical axes of the bargraph display. The luminance measurements shall be taken with a calibrated photometer and recorded.

9.6.4.2 Luminance Variation—Measure the illuminance of each segment on the center of its display surface in accordance with 9.6.4.1. Record the highest and the lowest readings...
obtained. The luminance variation \( (D_L) \) shall be determined using these readings in the following equation:

\[
D_L = \frac{\text{highest reading}}{\text{lowest reading}}
\]

9.6.5 Chromaticity—The bargraph meter chromaticity shall be determined by using one of the following three methods:

9.6.5.1 Method I—Spectrophotometer—Chromaticity shall be determined using a spectrophotometer, flat slab material of the same density and thickness of the shaped filter, and necessary calibration filters.

9.6.5.2 Method II—Spectroradiometric—Chromaticity shall be determined using a spectroradiometer, a completely illuminated meter, calibrated lamps of specific color temperature, and necessary calibration filters.

9.6.5.3 Method III—Visual Comparator—Chromaticity shall be determined by a color comparator, necessary high and low limit plastic or glass filters of known chromaticity, and calibrated light sources of specific color temperature.

9.6.6 Overload:

9.6.6.1 Momentary Overload—The voltage/current circuits of ac and dc meters shall be subjected to an application of 200 % of the rated full-scale value for 2 min. After 30 min at reference conditions (see 9.1) following the test, the meter shall be reset to zero and the change in indication shall be determined. The accuracy requirements of 8.3.3 shall be verified.

9.6.6.2 Sustained Overload—The meter shall be subjected for 8 h to an application of voltage/current 20 % greater than full-scale value. After 30 min at reference conditions (see 9.1) following the test, the meter shall be reset to zero and the change in indication shall be determined. The accuracy requirements of 8.3.3 shall be verified.

9.6.7 Temperature—The meter shall be tested, without alignment or adjustment, throughout the following temperature cycle:

9.6.7.1 Hold ambient temperature at 0 ± 2°C for not less than 24 h.

9.6.7.2 Increase ambient temperature in steps of 10° each, at 30 min/step, until 65 ± 2°C is reached, and hold at that temperature for not less than 4 h.

9.6.7.3 Reduce ambient temperature in steps of 10° each, at 30 min/step, until 25 ± 2°C is reached, and hold at that temperature for not less than 4 h.

9.6.7.4 At each temperature plateau (0, 65, and 25°C), a calibration cycle (see 9.5) shall be made. The temperature error is calculated as the change in indication caused by a temperature change of ±10°C from the three temperature points (0, 65, and 25°C).

9.6.8 Vibration—The meter shall be subjected to a simple harmonic motion in the X plane having an amplitude of 0.23 to 0.25 mm (0.46– to 0.50-mm total excursion), the frequency being varied uniformly between 500 and 2500 cycles/min for 20 min. The entire frequency range, from 500 to 2500 cycles/min and return to 500 cycles/min, shall be transversed at a rate of change of frequency of 200 ± 25 cycles/min. During the test, an input equal to 80 ± 5 % of the meter span shall be applied to the meter. After the test, the meter shall be examined visually and the accuracy verified in accordance with 9.6.1. Repeat for the Y and Z planes.

9.6.9 Salt Fog—The meter shall be tested in accordance with Practice B 117. The exposure time shall be 48 h followed by a 48-h drying period. The meter shall be examined visually after the test.

9.6.10 Temperature/Humidity Cycling—The meter shall be tested as specified in the following paragraphs. No adjustments during the test shall be made, other than the accessible controls employed for operation of the equipment.

9.6.10.1 Conditioning—To establish a reference condition, the meter shall be dried at a temperature not less than 40°C or greater than 50°C for not less than 2 h.

9.6.10.2 Calibration Cycles—Following the conditioning, a calibration cycle shall be performed as specified in 9.5 to indicate the satisfactory performance of the meter. This calibration cycle shall be conducted at 25 ± 5°C and 50 ± 5 % relative humidity. In addition, axial luminance shall be measured as specified in 9.6.4.1, except that only five segments of the display shall be measured. Throughout this test, the same five segments shall be monitored.

9.6.10.3 Temperature Cycling—Meters shall then be subjected to five 24-h cycles of temperature variation consisting of not less than 16 h at 65 ± 5°C and approximately 8 h at 25 ± 5°C. The relative humidity shall be maintained above a minimum of 95 % during the steady-state conditions. The transitions between temperatures shall be accomplished within 8-h period so that the time at the high temperature is not less than 16 h. Each transition shall be not greater than 1½ h if the meter remains in the chamber. If a two-chamber method is used, both chambers shall be stabilized at their appropriate settings before transferring the test units. The relative humidity need not be controlled during the transition periods. The chamber(s) used shall be proven able to maintain uniform temperature and humidity throughout the chamber.

9.6.10.4 Measurements—During the second cycle the measurements specified in 9.5 shall be taken at 65 ± 5°C with the meter remaining in the chamber. The meter shall be energized for as brief a period as required to complete the measurements. A warm-up period shall be permitted in which previous tests indicate a definite period is required for the meter to attain thermal stability. After the five complete cycles, the measurements specified in 9.5 shall be performed at 25 ± 5°C with the meter remaining in the chamber.

9.6.10.5 Conditioning—Upon completion of the tests, the meter shall remain inoperative for not less than 12 or greater than 24 h at a temperature at 25 ± 5°C and 50 ± 5 % relative humidity.

9.6.10.6 Humidity Cycling—The meter shall be operated continuously with an input equivalent to 80 ± 5 % of the meter span in an ambient temperature of 50 ± 5°C for a period of 8 h. The relative humidity shall be increased from 50 ± 5 % to 95 ± 5 % during the final 2 h.

9.6.10.7 Measurements—The meter’s calibration shall be checked and recorded (see 9.5) at 2-h intervals, for a total of four checks. At each check, the same five input values shall be used.

9.6.11 Workmanship—Meters shall be manufactured in such a manner as to be uniform in quality. The interiors of the meters shall be free from metal filings, grease or oil, foreign material,
dust, or other loose particles that will affect the performance, serviceability, or appearance of the meter.

9.7 Production Tests:
9.7.1 Visual, Mechanical, and Workmanship Examination—Meters shall be examined visually and mechanically to verify that materials, design, construction, physical dimensions, workmanship, and markings are as specified in this specification.

10. Certification Requirements
10.1 When specified in the purchase order or contract, a producer’s or supplier’s certification shall be furnished to the purchaser that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

11. Marking Requirements
11.1 Meter markings—Each meter shall be provided with an identification plate. Plastic identification plates shall be used when attaching to other than a flat surface. Unless otherwise specified, the following shall be marked on the identification plates:

11.1.1 Manufacturer’s name.
11.1.2 Manufacturer’s type or model number.
11.1.3 Manufacturer’s serial number.
11.1.4 Year of manufacture.
11.1.5 Country of origin.

12. Packaging Requirements
12.1 Product shall be packaged, boxed, crated, or wrapped to provide suitable protection during shipment and storage.
12.2 Preservation of meters shall be in accordance with Practice D 3951.

13. Quality Assurance
13.1 The manufacturer of the solid state bargraph meters shall maintain the quality of the meters that are designed, tested, and marked in accordance with this specification. At no time shall a meter be sold with this specification designation that does not meet the requirements herein.

14. Keywords
14.1 analog display; bargraph meter; digital display; edge-wise meter; electrical measurement; light-emitting diode; switchboard meter; solid state meter

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements are applicable to DoD procurements and shall apply only when specified by the purchaser in the contract or purchase order.

S1. Referenced Documents
S1.1 Military Specifications:
MIL–S–901 Shock Tests, H.I. (High-Impact), Requirements for Shipboard Machinery, Equipment, and Systems

S1.2 Military Standards:
MIL–STD–167–1 Mechanical Vibrations of Shipboard Equipment (Type I–Environmental and Type II–Internally Excited)
MIL–STD–461 Electromagnetic Emission and Susceptibility Requirements for the Control of Electromanetic Interference

S2. Dial Colors
S2.1 Dial Colors—For U.S. Navy applications, the dial color combination shall have black on a white background as standard (see 7.9.5). This color scheme optimizes visibility of meter in conditions of low ambient lighting, such as red-out locations.

S3. Vibration Tests
S3.1 Vibration Tests—The meter shall be tested in accordance with MIL–STD–167–1, Type I. During the test, an input equal to 80 ± 5 % of the meter span shall be applied to the meter.
S3.2 Examination After Vibration Tests—The meters shall show no evidence of breakage, permanent deformation, or loosening of parts and shall retain their serviceability. The meter shall meet the accuracy requirements of 8.3.3.

S4. Shock Tests
S4.1 Shock Tests—The meter shall be tested in accordance with MIL–S–901, Grade A, Class I, Type A. During the test, an input equal to 80 ± 5 % of the meter span shall be applied to the meter.
S4.2 Examination After Shock Tests—The meter shall show no evidence of screws, windows, or other parts being loose, cracked, or excessively damaged. The meter shall meet the accuracy requirements of 8.3.3.

S5. Electromagnetic Interference (EMI) Requirements
S5.1 The meter shall meet the following requirements of MIL–STD–461 for surface ships and submarines: CE 101, CE 102, CS 101, CS 114, CS 116, RE 101, RE 102, RS 101, and
RS 103. The applicable electric field levels for requirements
RS 103 shall be as follows:

<table>
<thead>
<tr>
<th>Frequency</th>
<th>E-field level</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 kHz – 2 MHz</td>
<td>10 V/m</td>
</tr>
<tr>
<td>2 MHz – 30 MHz</td>
<td>50 V/m</td>
</tr>
<tr>
<td>30 MHz – 18 GHz</td>
<td>10 V/m</td>
</tr>
</tbody>
</table>

S5.2 **Electromagnetic Interference Tests**—The meter shall
be tested in accordance with the applicable procedures in
MIL–STD–462.

S6. **Terminals**

S6.1 The meters shall be furnished with terminal connectors
in accordance with MIL-C-24308. The connector pin assign-
ments shall conform to S6.1.1 and S6.1.2

S6.1.1 **Digital Input**—The meter shall include two connec-
tors, which shall be as follows:

S6.1.1.1 M24308/4–1
S6.1.1.2 M24308/4–3.

S6.1.2 **Analog Input**—The meter shall include a connector
conforming to M24308/24–43 complete with jack screw hard-
ware, M24308/26–1. The connector pins shall be as follows:

S6.1.2.1 Input signal (+).
S6.1.2.2 Input signal (−).
S6.1.2.3 LED test input signal, if applicable.
S6.1.2.4 LED test input return, if applicable.
S6.1.2.5 Power supply.
S6.1.2.6 Power supply.

This standard is issued under the fixed designation F 1756; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide provides an overview and guide for the selection and implementation by shipowners and operators of a Fleet Management System (FMS) network of computer services in a client/server architecture (see Fig. 1). The FMS is based upon a wide area enterprise network consisting of an unspecified number of Shipboard Information Technology Platforms (SITPs) and one or more shoreside Land-Based Information Technology Platforms (LITPs), which provides management services for the shipping enterprise. The FMS can be understood as a computer system comprised of one or more LITPs and one or more SITPs. It can be characterized as mission critical 24 × 365 (24 h/day, 365 days/year).

1.2 The SITP (see Fig. 1) provides a set of software services, including:

1.2.1 Communications Services, to communicate between vessels and with shore via multiple wireless communication technologies;

1.2.2 Data Acquisition Services, providing access to shipboard system data as required for use by other systems and management purposes; and,

1.2.3 Executive Services, providing software process administration and control.

1.2.4 In total, the SITP provides the capability for multiple shipboard computer systems to share data with each other and to communicate with shore-based management or other vessels or both.

1.3 The SITP is understood to consist of integrated hardware, software, a data repository, and standardized procedures, which provide the ability to send, receive, process, transfer, and store data or messages in digital form in a common mode from shipboard systems or administrative utilities or both, and from designated sources outside the network, for example, systems accessed through wireless communication services, such as satellite, VHF, HF, and so forth. Shipboard systems include navigational, machinery control and monitoring, cargo control, communications, and so forth. The SITP also will provide the capability for the remote administration and maintenance of associated computer systems aboard the vessel.

1.4 The SITP requires an underlying hardware and network infrastructure, including a shipboard computer local area network (LAN), file servers, workstations, wireless communications transceivers, cabling, other electronic and optical devices, video display units, keyboards, and so forth.

1.5 The SITP also requires underlying system software providing network operating system (NOS) services, DBMS services, and other system software.

1.6 There also is a layer of shipboard application systems, which are designed to capitalize on the FMS infrastructure to share data with other shipboard systems and management ashore. Those systems also would be able to capitalize on the remote management capabilities of the FMS.

1.7 The LITP is an asset that can exchange operating and administrative data from individual ships and maintain a DBMS to support fleet management and other maritime applications. The LITP will support data repositories, file servers, workstations or personal computers (PCs), and a communication hub providing connectivity to distributed satellite services, VHF (very high frequency), HF/MF (high frequency/medium frequency), and land lines. The DBMS makes possible the development of knowledge-based “decision aids” by providing the ability to retrieve, process, and analyze operational data.

1.8 This guide does not purport to address all the requirements for a SITP, which forms a path for data for direct control of the operation or condition of the vessel or the vessel subsystems.

1.9 In all cases, it shall be possible for all units of navigation equipment resident on the Navigation Equipment Bus to operate and display essential operating data independently of the FMS.

1.10 In all cases, it shall be possible for all units resident on the Control, Monitoring, and Alarm Bus to operate and display essential operating data independently of the FMS.

1.11 In all cases, it shall be possible for all units resident on the Communications Bus to operate and display essential operating data independently of the FMS.

1.12 Values shown in this guide are in SI units.
1.13 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

3. Terminology

3.1 Definitions: Definitions of terms in this guide and described below are in accordance with Terminology E 1013 and ANSI X3.172 and X3.172a.

3.1.1 application program, n—a computer program that performs a task related to the process being controlled rather than to the functioning of the computer itself.

3.1.2 application programming interface (API), n—an API is a set of rules for linking various software components of a network.

3.1.3 automatic information system (AIS), n—automatic distribution of a ship’s voyage information to all interested parties, that is, other ships, port state, owner, and so forth.

3.1.4 baseband network, n—only one transmission can be on the network at any given time.

3.1.5 black box test, n—black box tests are based on the design specification and do not require a knowledge of the internal program structure.

3.1.6 certification, n—the process of formal approval, by an authority empowered to do so, of arrangements or systems for the reception, storage, or transmission of data and intelligence relative to the management, operation, or control of vessels.

3.1.7 client server database engine, n—a commercial data base management system serving as a repository for all critical ship operating and configuration information.

3.1.8 computer program, n—a set of ordered instructions that specify operations in a form suitable for execution by a digital computer.

3.1.9 computer system, n—a functional unit, consisting of one or more computers and associated software, that uses common storage for all or part of a program and also for all or part of the data necessary for the execution of the program.

3.1.10 configuration manager, n—utilities that determine the data to be collected, the processing and storage rules, the standard software functions that facilitate the interfaces between systems and the FMS process servers and other configuration parameters.

3.1.11 data replicator/message processor, n—a software module that is responsible for receiving, decoding, and storing communications and transmissions received from ships. This module also prepares data for transmission to a ship through the land-based communications hub.

3.1.12 document management system, n—an application that allows procedures manuals to be stored and accessed electronically on shipboard and to be updated electronically.

3.1.13 electronic mail system, n—a messaging and file transfer system for both ship and shore.

3.1.14 fault tolerance, n—the built-in capacity of a system to provide continued correct execution in the presence of a limited number of hardware of software faults.

3.1.15 fleet management system (FMS), n—a system of computer services in a client/server architecture, based on a wide area enterprise network consisting of an unspecified number of SITPs and the LITP. The FMS can be understood as an integrated system of software, hardware, communication protocols to be stored and accessed in the FMS database in a standard format.

3.1.16 independent, n—independent as applied to two systems means that either system will operate with the failure of any part of the other system excluding the source of power.

3.1.17 interface, n—the interface attribute describes the methods and rules governing interaction between different entities.

3.1.18 integration tests, n—tests performed during the hardware/software integration process before computer system validation to verify compatibility.

3.1.19 land-based communications hub, n—a land-based system that provides uniform access to multiple maritime satellite services, as well as access to public telephone networks, e-mail, and the internet.

3.1.20 local area network (LAN), n—a network that connects computer systems resident in a small area. For purposes of this guide, the SITP is considered a shipboard LAN with access to similar shoreside and shipboard units through radio and satellite telecommunication services.

3.1.21 MSAT—satellite communications service covering North America.

3.1.22 multitasking, n—the capability to handle more than one task at a time.

3.1.23 NAVTEX, n—a system for the broadcast and automatic reception of maritime safety information by means of a narrow-band direct-printing telegraphy.

3.1.24 network interface unit (NIU), n—the network interface units (NIUs) provide for connection and message translation to enable data streams from systems, both hardware and software, which may use various standard and proprietary communication protocols to be stored and accessed in the FMS database in a standard format.

3.1.25 ship information technology platform (computing), n—an integrated system of software, hardware, communication links, and standardized procedures that provide the ability to collect, process, and store information in digital form.

3.1.26 ship earth station, n—a mobile earth station for maritime service located aboard a ship. Typically, a small lightweight terminal with omnidirectional antenna with interfaces for a personal computer or any other data terminal equipment for message generation and display, for example, Inmarsat C, or a steerable antenna mounted on a stabilized platform, for example, Inmarsat A and B and M.

3.1.27 single failure criterion, n—a criterion applied to a system such that it is capable of performing its safety task in the presence of any single failure.

3.1.28 software, n—programs, procedures, rules, and associated documentation pertaining to the operation of a computer system.

3.1.29 software cycle—the software cycle typically includes a requirements phase, a design phase, an implementation phase, a test phase, an installation and checkout phase, and an operation and maintenance phase.

3.1.30 validation—the test and evaluation of the integrated computer system, hardware and software, to ensure compliance with the functional, performance, and interface requirements.

3.1.31 verification, n—the process to determine if the product of each phase of the digital computer system development process satisfies the requirements set by the previous phase.
3.1.32 voyage data recorder (VDR), n—a store of information, in a secure and retrievable form, concerning the position, movement, physical status, command, and control of a vessel over the period leading up to a marine casualty.

3.1.33 white box test, n—white box tests require a knowledge of the internal program structure and are based on the internal design specification.

3.1.34 workstation, n—a computer and associated visual display unit (monitor) configured as an I/O unit to perform certain tasks.

4. Significance and Use

4.1 Competent information management is essential for safe and productive operation and regulatory compliance. A short list of the functions affected includes decision aids for navigation, communications, ship handling, machinery control, cargo operations, maintenance and repair, personnel records, and environmental protection.

4.2 The shipbuilding and shipping industries have identified a need to develop comprehensive standards and guides for implementing computer-based shipboard data management systems.

4.3 The FMS may include single or multiple SITPs and single or multiple LITPs and provides the means to integrate shipboard and shore-based computer systems with multivendor connectivity, distributed processing, and electronic data interchange between noncompatible networks, computers, workstations, and peripherals and maintain databases, which promote safety of life at sea, protection of the environment, and operational efficiencies throughout the life cycle of the vessel/fleet. The FMS may incorporate satellite gateways to coastal communication hubs providing access to land-based networks, such as telephone lines, facsimile, e-mail, and expanded satellite services through land earth stations.

4.4 The SITP can be configured to provide the ship’s control center with access to local control centers, such as for cargo operations, which may be located on the main deck.

4.5 This guide has provisions relevant to all components of the FMS platform including the ship earth station, interface devices for subsystems and administrative systems connected to or forming part of the network, communication services, and certain land-based facilities under the direct control of the ship’s management.

4.6 It is the intent of this guide to provide guidelines for the design and implementation of open client/server architecture for computer and communication networks for shipboard and shore-based applications.

4.7 This guide is intended to assist vessel owners, designers, shipyards, equipment suppliers, and computer service providers in the development of contract technical specifications, which detail the services to be supported, performance required, and criteria for acceptance for specific FMS installations.

5. FMS Architecture

5.1 Network Design—There is an underlying computer network to support the FMS. The functions of the FMS enable a communication network that provides for the exchange of information between nodes or devices capable of transmitting or receiving information in the form of electronic or optical signals. The process is enabled by communication protocols, which define the rules that must be implemented in the hardware and software. The text of this guide is predicated on a network architecture conforming to the Open Systems Interconnection Reference Model (OSI/RM). See Guide F 1757.

5.2 Network Management:

5.2.1 The FMS is based upon a wide area network (WAN) consisting of a number of LANs, which are dispersed geographically over large areas and are linked through wireless communications by bridges and gateway devices. The group responsible for managing the FMS will normally be located in the principal shoreside office. The primary task of the network management system is to oversee and report on the operation of the network, which may comprise products from many different vendors.

5.2.2 Security—A security function should be provided that is responsible for the following:

5.2.2.1 Data confidentiality;
5.2.2.2 Data integrity;
5.2.2.3 Data authentication; and,
5.2.2.4 Access control.

5.3 Database Model—Database maintenance and availability are key features of the FMS. Each SITP and the LITP will maintain separate databases. Each FMS site will incorporate a database management system, including replication capability, as part of each SITP and LITP installation.

6. Shipboard Information Technology Platform (SITP) Connectivity

6.1 A key objective of the SITP is to facilitate sharing of data among shipboard systems (see Fig. 2). The shipboard systems, which are candidates for connection to an SITP include, but are not limited to, the following:

6.1.1 Shipboard Operating Systems—Shipboard operating systems are active systems and may acquire information from sensors or databases and exercise control internally or transmit data for administrative purposes or for application in knowledge-based decision aid systems.

6.1.1.1 Integrated Bridge System—This system comprises the integrated bridge system bus, the navigation equipment bus, and the control, monitoring, and alarm bus.

6.1.1.2 Integrated Bridge System Bus—The integrated bridge system bus provides connectivity for the navigation equipment bus and the control, monitoring, and alarm bus and is a controlled gateway to the administrative network.

6.1.1.3 Navigation Equipment Bus—The navigation equipment bus provides systemwide connectivity for any or all of the following or any additional units associated with the navigation of the vessel: gyro compass/autopilot; global positioning system (GPS); dead reckoning (DR) navigation system; speed and distance indicator (Doppler log); sonic depth finder; electronic chart system (including, but not limited to, ECDIS); rate of turn indicator (ROTI); radar/ARPA (automatic radar plotting aids); radio direction finder; and voyage data recorder (VDR).

6.1.1.4 Control, Monitoring, and Alarm Bus—The control, monitoring, and alarm bus provides systemwide connectivity for any or all of the following or any additional units associated...
Shipboard Operations Administrative Network:

Integrated Bridge System Bus

- Ballast Control
- Mach. Control
- Liquid Cargo
- Fire Control

Trim & Stab.
Interior Comm.
Reefer Controls
HVAC Controls

Navigation Equipment Bus

- Gyro/Autopilot
- Global Pos. Sys.
- Radar/ARPA
- Depth Finder

- DR Position
- Speed & Dist.
- ECDIS
- Rate of Turn

Control, Monitoring & Alarm Bus

Integrated Bridge System (IBS)

FIG. 2 SITP Data Flow (Typical)
directly with control of the vessel: machinery control, monitoring, and alarm; liquid cargo control; inert gas control; ballast control; fire detection and alarm; loading (trim and stability; hull stress); internal communications; WT door and fire door controls; controls for refrigerated cargo; and HVAC controls.

6.1.2 Communications Bus—The communications bus provides connectivity for any or all of the following or any additional units providing communication facilities on board the vessel: Inmarsat A, B, M; Inmarsat C; VHF radiotelephone; MF/HF SSB radiotelephone; cellular; and GMDSS (Global Maritime Distress Safety System—see Appendix X3).

6.1.3 Administration System:

6.1.3.1 Ship-to-Shore Communications:

Electronic mail and file transfer, Connection to local telephone systems, and Sailing instructions (weather routing).

6.1.3.2 Cargo Planning:

Stability and trim, Container ordering, Cargo manifests, Custody transfer procedures and records, and International Maritime Dangerous Goods Code.

6.1.3.3 Fuel Management—Speed/Distance/Consumption:

Fuel rate, Running inventory, Fuel quality records, Bunkering checklist, Bunker planning—grades and quantities, and Cargo heating.

6.1.3.4 Inspections, Maintenance, and Repair:

Inspection schedules, Maintenance and repair (M and R) schedules and records, and Spare parts inventory control (use, ordered, received, and cost).

6.1.3.5 Quality Management:

ISM Code compliance, Quality procedures and records (ISO 9000), and Auditing.

6.1.3.6 Personnel and Safety Management:

Employment records management—payroll, Training and certification, Hazard communication (benzene, asbestos), Respiratory protection, and Occupational health monitoring.

6.1.3.7 Ship’s Documents:

6.1.3.8 Reports:

Automatic information system (AIS) and Voyage data recorder (VDR).

7. Shipboard Information and Technology Platform (SITP)

7.1 The SITP consists of the software and hardware required to support a distributed computing network based on the client/server model. In general, the SITP will be optimized to respond to a single LITP. For cases in which the SITP will respond to multiple shoreside platforms, a hierarchy should be defined. The SITP consists of layers of computer services and underlying layers of system services, including a network operating system and a database management system.

7.1.1 Computing Model—Client/server computing is expected to be the computing model for the SITP. Client/server is a joint operation in which specific computers perform specific tasks. Server tasks generally involve file sharing, database management, communications management, and so forth. Client tasks, on the other hand, are generally active and are defined by the application.

7.1.1.1 Server(s):

(a) Comprises software that is resident on an intelligent machine (a computer);
(b) Is a provider of services. The services may include database services (DBMS), communication services, and processes;
(c) Is a shared resource. One server can serve several clients;
(d) Is transparent to the user. Clients and servers communicate by a messaging interface; and,
(e) Is normally a dedicated PC.

7.1.1.2 The client(s) is normally software that is resident on a PC or work station.

7.1.1.3 Quality—Design, development, modification, replication, and installation should be subject to a documented quality plan. At a minimum, the areas of responsibility, performance, and acceptance criteria should be addressed in the quality plan.

7.1.1.4 The design and testing of the computer services should ensure that:

(a) The implementation satisfies the applicable requirements, which may also include statutory and classification requirements;
(b) Design documentation will show that specification requirements can be traced through all levels;
(c) Module interfaces and dependencies are clearly defined and identified;
(d) Estimates of memory capacity, central processor unit, and bandwidth are reliable and can support hardware selection;
(e) Test procedures are defined and carried out in parallel with the design process; and,
(f) Documentation is subject to formal review.

7.1.2 Required Underlying System Services:

7.1.2.1 Network Operating System—A network operating system supports the following services that should be transparent to the user:

(a) Initialization of the system services;
(b) Enables applications throughout the network;
(c) Provides for multiple user access to programs and database and file services;
(d) File and print services—remote access, read, write, download, and upload;
(e) Gateways to independent networks—the ability to access a remote system; and,
(f) Network management.

7.1.2.2 Security Management—Security management provides an integrated platform-wide, including network operating system and compliant applications, security system that includes:
(a) Discretionary access control (DAC) in which the users may protect their own objects;
(b) Mandatory access control (MAC) in which users may read or write objects for which they have clearance. Users may read objects at the same or lower class and write objects at the same or higher class;
(c) Isolation of the security kernel from noncritical systems;
(d) User authentication/identification;
(e) Audit and log of security-related transactions—log-ins, read or write operations on objects, and log-outs;
(f) System testing;
(g) Users’ guide;
(h) System manual; and
(j) System documentation.

7.1.2.3 Encryption—Radio communications between SITPs and LITPs are exposed to electronic monitoring, and messages transmitted in clear text will be exposed to eavesdropping and intrusion. Data encryption is the most effective protection against such intrusions and should be available for security-sensitive communications. The encryption protocol should provide for multiple algorithms and the assignment of separate algorithms for different types of data. A critical element of the encryption program is the control of data encyphering and data decyphering keys, a key management system. This system is responsible for key origination, application, recording, assignment, and deletion.

7.1.2.4 Virus protection—Includes programmed virus scanning software and floppy disk control.

7.1.2.5 Miscellaneous—Includes automatic checking and reporting of memory errors and automatic reset and reboot after power interruption.

7.1.3 Database Management System:
7.1.3.1 The database management system supports a data repository that provides for storage of data in digital form and manages:
(a) Data acquisition and storage;
(b) Data replication on demand, scheduled or event driven;
(c) Integration of information at multiple remote sites;
(d) Open database connectivity;
(e) Query language;
(f) Concurrency/multiple users; and,
(g) Referential integrity.

7.1.3.2 Database Security—The DMBS should incorporate protection against improper access, improper modification of data (ensure data integrity), and improper denial of access. It should provide for:
(a) Operational Integrity—This addresses the serialization and isolation properties of transactions. Serialization means that the concurrent run of a set of transactions will give identical results as a sequential run of the same set of transactions.

(b) Logical Integrity of Data—Allowed range.
(c) Accountability and Auditing—Record of all read or write access to data.
(d) Privacy—Control of employment, medical records, and so forth.
(e) Delimitation—Control of information transfer between programs.

7.2 SITP Services

7.2.1 The SITP services, as shown in Fig. 1, are required to provide overall command and control of the SITP. The executive has overall responsibility to monitor the SITP and control the distributed processes that operate as platform services. The SITP executive itself is a series of services each of which are responsible for specific tasks. The SITP provides a layer of insulation and control between high- and low-level processes. It uses a set of structured APIs and internal communication channels for message exchange.

7.2.2 Executive Services—The following sections describe the services provided by the SITP executive. These services are each responsible for the orderly registration, control, audit, and monitoring of SITP compliant software processes on the server and supported workstations for their specific function.

7.2.2.1 Process Management—Process control refers to starting, staging, pausing, resuming, and stopping. An SITP process may be an SITP internal process, network operating system process, or an SITP compliant application. The process management interfaces with the SITP compliant process through the SITP APIs and with the process management database. Each physical computer within the SITP will have a process management function. All SITP processes are registered in the SITP process management database that describes the important attributes of the process. All process information is available to the SITP compliant applications.

7.2.2.2 Health Management—Health management is used to check, on an ongoing basis, the current health of all SITP compliant processes and record that finding in the health management database. This information is available to SITP compliant applications.

7.2.2.3 Performance Management—Performance management is used to observe the efficiency of any particular entity in the system. It is through the SITP performance management facilities that a process can make application-specific data available for monitoring. Furthermore, the data is modeled in such a way as to allow a general purpose monitoring application to display performance data for any participating monitored object.

7.2.2.4 Logging Management—The logging management interfaces with the SITP compliant process through the SITP APIs and with the logging management database. An SITP compliant process, locally or remotely, may send unsolicited events to the logging management database. The logging management directs the logging management database to store the event in the event history.

7.2.2.5 Alarm Management—The alarm management interfaces with the SITP compliant process through the SITP APIs and with the alarm management database. An SITP compliant process, locally or remotely, may send an unsolicited alarm of
a particular alarm type to the alarm management for processing. The alarm management directs the alarm management database to store the alarm in the alarm history.

7.2.2.6 Schedule Management—The SITP schedule management will define a standard API for applications to schedule future running of programs, either as one-time or recurring jobs. A history of requests and execution will be maintained. Compliant applications will have access to this data for display, reporting, audit, or diagnostic purposes. Programs can be scheduled to run based on several criteria, such as time and data, or a range of times. Programs also can be configured to run on a recurring basis. The SITP schedule management also will keep a history of execution.

7.2.2.7 Time Management—The SITP will define a standard API for applications to synchronize with a master clock. This will counter the time drift encountered in computer real-time clocks and allow for the synchronization of time stamps for remote systems. In a shipboard system in which distributed systems execute autonomously, synchronization of events is a critical function. The time management is responsible for maintaining the master clock and providing an API for various SITP services to access that information. To present a uniform reference point, the time management should operate in Z (Zulu) Time and date stamp in an accepted international format and arranged to display world local times on demand.

7.2.2.8 Localization Management—The SITP localization management interfaces with the SITP compliant process through the SITP APIs and with the localization management database. An SITP compliant process can request localization information, such as language type, collating sequence, date and money formats, system messages, application strings, and any other locale-related information.

7.2.2.9 Debug Management—The SITP debug management interfaces with SITP compliant processes through the client APIs and with the debug management database. An SITP compliant process can send debug data to the debug management for processing. The debug management will record this debug information in the debug management database.

7.2.2.10 Backup Management—The backup management will service client backup requests. It interfaces with SITP compliant processes through the client APIs and with the backup management database. The SITP platform will define a standard API for the backup and restoration of application files and file sets. A history of backup and restore operations for volumes and sets will be retained. Compliant applications will have access to this data for display, reporting, audit, or diagnostic purposes.

7.2.2.11 Test Management—The testing management will intervene between client test requests and targets. It interfaces with the SITP compliant process through the client APIs and with the testing management database. An SITP compliant process can request test execution or test history information.

7.2.2.12 Messaging Management—The SITP messaging management will define a standard API for applications to transport data among all registered entities on the global SITP network. This will allow applications to send and receive arbitrary data to and from any other SITP application. This includes ship to shore, ship to ship, and shore to ship. A hierarchical naming scheme is supported by the messaging management allowing for orderly classification of communication endpoints. The messaging management will use communications facilities as a transport mechanism for interapplication messages. The communication abstraction provided by the messaging management allows for additional transport mechanisms to be used in the future.

7.2.2.13 Replication Management—The SITP replication management is a generalized mechanism that may be used by SITP application providers to build distributed applications that operate within the SITP environment. The services provided by this facility include the following:

(a) Rules-Based Distribution—Configurable distribution of transactions, at the table level, between ship- and shore-based system sites. SITP can be configured to send all, or selected subsets of, information between system sites at flexible intervals. Further, a redistribution feature allows transactions to be forwarded to multiple sites based on system configuration parameters.

(b) Distribution Control Mechanisms—To maintain data integrity, strong control mechanisms are required to serialize, log, and archive all incoming and outgoing transmissions. Disaster recovery mechanisms are required to resend failed transmissions or allow a complete refresh synchronization between system sites. Confirmation of sent and received transmissions must be passed between system sites to ensure data integrity.

(c) Batched Distribution—As sustained real-time connections between system sites can be costly, the platform will support batched groups of transactions to be transmitted in compressed packets during low-cost time windows.

7.2.2.14 Enterprise Management—Several of the services offered by the executive system provide a means of managing various aspects of the SITP system. The enterprise management allows SITP interfaces to be available for use by remote users. The enterprise management would enable a user at a shore site to invoke SITP APIs on a specific ship.

7.2.2.15 Configuration Management—The configuration management handles requests from client processes via API calls. These requests will either request particular configuration settings or a change to a configuration setting. These client processes can be any SITP compliant process. This service is responsible for updating the configuration database as required and notifying other processes affected by the configuration change.

7.2.3 Data Acquisition Services:

7.2.3.1 The SITP data acquisition module is responsible for communicating with the various shipboard control systems or data collection units to acquire data. The SITP data acquisition is responsible for the orderly registration, control, audit, and monitoring of SITP compliant software processes on the server and supported workstations for data acquisition. The SITP data acquisition will provide a framework in which custom interfaces can be developed to a variety of control systems and data acquisition units.

7.2.3.2 Data acquisition from the monitoring and control bus and the navigation equipment bus generally will be read only. A gateway will be interposed between the integrated
bridge system bus and the administrative and communications networks. The gateway will provide the necessary hardware and software to enable dialog between the integrated bridge system and the administrative and communication networks platform and to enforce the one-way communication where required. Data flow on the administrative and communication networks generally is unrestricted except as may be limited by the security mode. Access to the integrated bridge system bus will be regulated as noted.

7.2.4 Communications Services—The communications manager must serve both remote and local users. To avoid connect-time client server blocking, it should provide for asynchronous dialog with the database server that queues client requests, establishes a link, confirms receipt, and satisfies the queries according to priority without blocking either the client or server. The communications manager provides a common systems interface and support for:

7.2.4.1 Multiple wireless communication services, which may include Inmarsat A, B, M and C; MSAT; ARGOS; Orbcamm; and Mobile Datacom.

7.2.4.2 Radio communications include VHF, HF/MF, and cellular.

7.2.4.3 Route diversification, least cost routing, and carrier choice.

7.2.4.4 Message log and cost allocation.

7.2.5 SITP Compliance—SITP compliance is required for software applications to have access to the services of the SITP. APIs will allow SITP compliance for third-party software applications. An SITP compliant software entity will allow for seamless integration into the platform. There will be four levels of compliance based upon the extent of SITP services used:

7.2.5.1 Level 1:
- Process management,
- Logging management,
- Messaging management, and
- Replication management.

7.2.5.2 Level 2—Includes Level 1 plus the following:
- Alarm management,
- Time management, and
- Configuration management.

7.2.5.3 Level 3—Includes Level 2 plus the following:
- Debug management,
- Backup management,
- Test management, and
- Enterprise management.

7.2.5.4 Level 4—Includes Level 3 plus the following:
- Health management,
- Performance management,
- Schedule management, and
- Localization management.

7.3 Application Programming Interfaces—APIs will be required for third-party applications to use SITP services.

7.3.1 Overview of APIs—The term “application programming interface” (API) is defined as a software tool kit that can be used as a building block that facilitates connections primarily between applications and other constituent network software, but that also can provide linkages for other elements of the network (see Fig. 3). The function of the network operating system is to control shared resources and establish transactions among applications. In multivendor networks without commonality, APIs provide the required link.

8. Land-Based Information Technology Platform (LITP)

8.1 The LITP is the control and communication center of FMS. It provides the infrastructure, software, and hardware, necessary to provide computing and communication services for the management of a wide area network (WAN) of SITPs and any auxiliary shoreside installations. The design profile generally will replicate that of the SITPs it manages, expanded, and optimized as required by the size of the fleet. The underlying service, that is network operating system and database management system, as well as the LITP services, provide the same functions as corresponding services of the SITP described in 7.1.2 and 7.2 except as follows:

8.1.1 Data Acquisition Services—Typically for the LITP, data acquisition from control systems will not be required.

8.1.2 Data Management—The LITP data management function will include acquiring, processing, and warehousing operating data from the various SITPs under its direction. It also may acquire data from any associated shoreside version or from other sources. It will oversee the flow of data to SITPs or LITPs.

8.1.3 Communications Manager—The communications manager will support a communications hub with access to land lines that may include telephone, telefax, e-mail, cellular, and land earth stations.

8.1.4 Configuration Manager—The configuration manager for the LITP responds to requests to reconfigure elements of the WAN, that is, the SITPs and subsidiary shoreside platforms, as well as to its local network.

9. System Hardware

9.1 The selection of system hardware for both the SITP and the LITP must consider a number of factors that are dependent on the nature and the criticality of the applications supported by the FMS. Guidance to assist the designers in the selection of hardware is provided in Appendix X4.

10. Fault Tolerance

10.1 The level of fault tolerance necessary for each FMS installation should be determined as a function of the criticality
of the applications supported by the system. A description of varying levels of fault tolerance is provided in Appendix X5.

11. Communications Bus

11.1 The communications hub provides the physical interface between the communications software and the various transceivers may include, but are not be limited to, the following:

   11.1.1 Satellite Communications:
   11.1.1.1 Circuit-Switched Mode—Inmarsat A, Inmarsat B, Inmarsat M, and MSAT.
   11.1.1.2 Store and Forward Mode—Inmarsat C and Orbi-comm.

   11.1.2 Radio Communications:
   11.1.2.1 Medium and Long Range—MF (300 kHz to 3 Mhz); HF (3 to 30 MHz); emergency communication (500 kHz); weather fax; and radio telex.
   11.1.2.2 Short Range—VHF (30 Mhz to 300 mhz) and cellular.

   11.1.3 GMDSS—See Appendix X3.

12. Demonstration and Validation

12.1 General—Evidence of a satisfactory degree of reliability in the design, manufacture, and installation of the equipment and systems comprising the FMS is to be demonstrated. In general, this demonstration consists of series of certifications, verifications, validations, tests, and trials.

12.2 Test Philosophy—Testing shall be of hierarchical nature, moving from the equipment unit level through testing at the integrated system level to final user testing in the installed environment.

12.3 The system hardware will be tested to ensure that no part of the system can be overstressed as by voltage transients during operation or testing, that components are electrically rated compatible with other design constraints to allow for part parameter variations and transient conditions, and a safe margin in operating temperature.

12.4 LAN Software Assessment:

   12.4.1 As used in this guide, software assessment refers to the methodology for verification and validation of the FMS software. Verification focuses on the functional design, whereas validation focuses on whether the system satisfies the requirements. Software is difficult to test. In contrast to hardware, it does not wear out, it does not operate within discrete parameters, and testing is largely qualitative and inferential. In addition, redundancy is not an effective backup.

   12.4.2 Verification and validation of software products should be carried out for individual products and for the integrated system. There will be a defined software demonstration and validation test plan created for each installation, and the SITP and FMS infrastructure will be tested against that plan. In general, software testing shall be formalized at three points in the development.

   12.4.2.1 Unit Tests, of individual modules in isolation to verify logic and interface characteristics. This is accomplished concurrently with software development.

   12.4.2.2 Integration Tests, of the different units to validate interoperability in accordance with design criteria.

12.4.2.3 Acceptance Tests, of the complete system, including all features and elements of the software in a fully configured hardware state without any element of simulation and in a normal operating environment.

12.5 Tests and Trials:

   12.5.1 Unit Tests (Alpha Testing), are white box tests required for testing individual modules and combinations of modules in isolation to verify logic and interface characteristics. They may focus on the lower levels of the protocol and should be started as soon as the software design will permit.

   12.5.2 Integration tests are white box tests, the purpose of which is to bring together the various layers or segments of the software and hardware, including communication links and gateways, and to test them step by step as the integration proceeds.

   12.5.3 End User (Acceptance) Tests—These are tests of the complete system including software and hardware, as well as communication links and gateways. They should be conducted as installed or in simulated environment (mock-up). For the FMS, this will normally include at least one SITP and one LITP. These are black box tests requiring multiple iterations. At a minimum, the following should be included:

       12.5.3.1 Load/Stress Testing—To confirm the system can handle the peak load conditions, internal and external traffic.
       12.5.3.2 Security Testing—To reveal weak spots in the system by repeated attempts to defeat the security controls.
       12.5.3.3 Performance Testing—These tests exercise all of the software applications, communications links, and database management systems.
       12.5.3.4 Hardware Compatibility Testing—To determine the margin of hardware resources, memory, disk space, speed, and so forth, over requirements.
       12.5.3.5 Configuration Testing—To determine how the systems respond to required alternative configurations in hardware or software.

12.6 Operation and Maintenance—This phase will focus on all aspects of system management including:

       12.6.1 System configuration and modification,
       12.6.2 Anomaly identification and resolution,
       12.6.3 Document control (updating),
       12.6.4 Communication interfaces,
       12.6.5 Latencies, and
       12.6.6 Hardware replacement.

13. Human Interface

13.1 In the design of the user interface to the SITPs and the LITP, reference may be to recognized standards.

13.2 Visual Display Unit (VDU):

13.2.1 The size, color, contrast, and density of text and graphics should be read or interpreted easily from the operator position under all operational lighting conditions. Typeface should be an internationally recognized simple, cleartcut design similar to Helvetica medium.

13.2.2 VDU pages should have a standardized format. Information and functional areas should be presented in a consistent manner.

13.2.3 An overview page or pages should be available to explain the paging system.
13.2.4 Each page should have a unique identifying label shown on the screen.

14. Training and Documentation

14.1 General—Regardless of the technical excellence of the FMS software and hardware, operator training is essential to its successful application. The disconnected nature of ship operations serves to emphasize the need for shipboard personnel to be trained in depth on the operation and maintenance of the system.

14.1.1 It is a condition of this guide that formal training in the operation of the FMS is available.

14.1.2 Administrators and users should be trained in and demonstrate their knowledge of step-by-step procedures for operation of the FMS including, to the extent necessary, instructions for associated subsystems, the administrative network functions, ship earth stations, and the land-based communications hub. The program of instruction should include the following at a minimum:

14.1.2.1 Management of local area networks,
14.1.2.2 Management of wide area networks,
14.1.2.3 Client server systems,
14.1.2.4 Network operating systems,
14.1.2.5 All installed hardware,
14.1.2.6 Maintenance and repair,
14.1.2.7 Knowledge of the regulations concerning telecommunications,
14.1.2.8 Administration of the SITP and FMS systems.

14.2 Documentation:

14.2.1 Documentation can be defined as “the aids provided for the understanding of the structure and intended uses of an information system or its components” (ANSI) and system documentation as “the collection of documents that describe the requirements, capabilities, limitations, design, and operation of an information processing system” (ISO). Both definitions are relevant for the purposes of this guide. In addition, the documentation should comply with the provisions of ANSI/IEEE 1063 as a minimum.

14.2.2 User documentation for the SITP may be presented in a tutorial mode and should include detailed instructions for all permitted operations and for such system adjustments or repairs as may be practicable for on board personnel.

14.2.3 Administrator documentation for the FMS should include, in addition to the user documentation, complete reference material necessary to administer the system.

15. Keywords

15.1 communications service; data acquisition service; DBMS (database management system) service; executive services; fleet management system network; land-based information technology platform; network operating system; shipboard information technology platform

## X3. OVERVIEW OF RADIOCOMMUNICATIONS EQUIPMENT REQUIRED FOR GMDSS

### X3.1 See Fig. X3.1 for an overview of radiocommunications equipment required for GMDSS.
X4. SYSTEM HARDWARE

X4.1 Electromagnetic Interference (EMI)—Equipment to be situated in a shipboard open deck environment must be considered as exposed to high levels of radiated and conducted EMI. Because of a large glass area, the enclosed navigating bridge is treated as an open deck area. The sources of EMI can be classed as intentional emitters and nonintentional emitters. Nonintentional emitters are limited by standard to a level of 10V/m radiated EMI under test conditions. Intentional emitters, which include radar, radio, and so forth, generally are not limited as to radiated strength or direction. In addition to fixed emitters, the navigating bridge area routinely is exposed to radiation from mobile emitters, such as, walkie talkies, with levels of EMI potentially hostile to sensitive electronic equipment. See IEC 945 and IEC 533.

X4.2 Physical Layer:

X4.2.1 Topology—The topology of a network is defined by the logical configuration of the nodes and the interconnecting branches.

X4.2.1.1 Star—In practice, the practical execution for both bus and ring topologies is often star shaped with arms radiating from a central hub to each node or station. The wiring within the hub is connected so that logically the system behaves as a bus or ring. This arrangement allows for diagnosing and isolating faulted circuits or equipment without closing down the entire network.

X4.2.1.2 Bus—The bus (see Fig. 1) is the predominate topology found in LANs generally in conjunction with the Ethernet protocol and using STP cabling. The nodes share the bus, and as a result, only one station can broadcast at a time requiring some form of access control, which is provided by the Ethernet protocol. In the simplest form, transmissions from one node can be read at all the other nodes. The effective maximum transmission speed for the standard Ethernet configuration is about 8 Mbps, and this drops rapidly as traffic increases. This speed can be doubled by duplexing. Switched Ethernet provides each device with its own segment so that it has access to 10-Mbps bandwidth without contention.
X4.2.1.3 Ring—The ring network is characteristic of the token ring protocol. Although commonly shown in ring form, the practical execution is a star-shaped assembly which behaves logically like a ring. Arms from a central concentrator, the multistation access unit (MSAU), radiate to each station. Implementation should be in accordance with IEEE 8802.5 at 16 Mbps over STP.

X4.2.2 Cabling—The type of cable to be used will be governed by the length of the cable, the electromagnetic environment, and the bandwidth.

X4.2.2.1 Copper:
(a) Twisted Pair—Available as “Unshielded Twisted Pair”—UTP or as “Shielded Twisted Pair”—STP. UTP is not protected against noise caused by radiated EMI and generally is not suitable for shipboard use for this reason. STP is provided with a shield of copper foil or copper braid to reduce system noise as a result of radiated EMI.
(b) Coax—The cable consists of insulated central conducting solid copper core surrounded by one or more foil or mesh shields separated by insulation. The central conducting core carries the signal and the shield provides the ground. Coax cable is available as thick coax (10Base5 has been applied as the network backbone) or thin coax (10Base2).

X4.2.2.2 Optical Fibers—Optical fibers possess three important advantages over copper conductors:
(a) Immunity to noise from radiated or conducted EMI;
(b) Very high transmission speeds—100 Mbps over paths of up to 2 km for glass fibers. This is the medium of choice for backbone service; and,
(c) Improved security.

Also available with plastic fibers, but with speeds limited to under 10 Mbps and paths of less than 100 m.

X4.3 Servers—The standard configuration for the shipboard local area network will comprise a process server, a communications server, and a database server, which may be allocated to one or more computers. Estimated minimum requirements for the computer(s)/servers are:

X4.3.1 Processor:
X4.3.1.1 Speed—90 mhz,
X4.3.1.2 Two instructions per clock cycle,
X4.3.1.3 45 MFLOPS (floating point operations/second), and
X4.3.1.4 Scalable.

X4.3.2 Memory (RAM), 40-MB ECC (error, checking, correcting, and reporting).

X4.3.3 Storage Devices:
X4.3.3.1 1.05-GB hot swap fast SCSI-2 disk,
X4.3.3.2 3.5-in., 1.44-MG floppy disk drive, and
X4.3.3.3 CD-ROM—internal SCSI-2, quad speed.

X4.3.4 Network Interface Card.

X4.3.5 Color Monitor (Video Display Unit):
X4.3.5.1 15 in., high resolution, integrated 800 × 600, noninterlaced, refresh rate 72 MHz; and,
X4.3.5.2 512-KB standard video memory.

X4.3.6 Graphic Card.

X4.3.7 Multimedia Sound System Support.

While nominally acting as client, workstations may in addition be configured as servers. When configured in this manner, the requirements of X4.3 would apply. The following apply to a stand-alone workstation:

X4.4.1 Processor:
X4.4.1.1 Speed 75 MHz and
X4.4.1.2 Scalable.

X4.4.2 Memory (RAM), 16-MB ECC.

X4.4.3 Storage Devices:
X4.4.3.1 540-MB fast SCSI-2 hard disk;
X4.4.3.2 3.5-in., 1.44-MB floppy disk drive; and
X4.4.3.3 CD-ROM, internal SCSI-2, quad speed.

X4.4.4 Network Interface Card.

X4.4.5 Graphic Card.

X4.4.6 Multimedia Sound Support System.

X4.4.7 Color Monitor, see X4.3.5.

X4.5 Power Sources—The power supply from the ship’s mains may be subject to the variations given in Table X4.1 (see also IEC 92.101):

X4.5.1 Power supply to SITP may be arranged as follows:
X4.5.1.1 From ship’s main or emergency power supply with power conditioner as required to provide the required quality and backed up by a closed transition uninterruptible power supply with a minimum reserve capacity of 15 min.
X4.5.1.2 An on-line uninterruptible power supply with a minimum reserve capacity of 15 min supplied from the ship’s main with closed transition backup.

X4.6 Embedded Programs—Embedded programs should be documented using the following format:

X4.6.1 The procedure’s actual calling name from within the program should be listed along with a one-line description statement for the calling name. The statement’s purpose is to describe clearly the task associated with the procedure’s name.
X4.6.2 A list of input/output parameters, a description statement for each parameter that describes the task associated with the parameter’s name, a statement as to whether the parameter is an input or an output of the procedure, and a range of valid values for each parameter that may be passed into or out of the procedure.
X4.6.3 A list of calling/called procedures, a description statement for each procedure that describes the task associated with the procedure’s name (this statement should be the same as the one describing the procedure’s calling name), a statement as to whether the procedure is called from within the routine or is the caller of the routine, and the name of the module in which the calling/called procedure can be found.

### TABLE X4.1 Power Sources Variations

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Permanent</th>
<th>Permanent</th>
<th>Transient</th>
<th>Transient</th>
<th>Recovery Time, s</th>
</tr>
</thead>
<tbody>
<tr>
<td>Voltage</td>
<td>+6, +10</td>
<td>±20</td>
<td>±10</td>
<td>±10</td>
<td>1.5</td>
</tr>
<tr>

</tbody>
</table>

Note: Voltage and frequency variations may occur simultaneously.
Total harmonic loading—5 %. Harmonic loading at any single frequency—3 %.
X4.6.4 A synopsis describing the program flow for the procedure. This synopsis should be a detailed, plain language narrative of what the code is doing.

X4.6.5 A revision history for the procedure that includes the data and a description of the change. The description should include the new revision level for the overall program that has resulted from the module modification.

X4.7 Environmental Conditions—The following are to be considered minimum levels. If the equipment is to be part of a system subject to regulatory body approval, then the requirements of the regulatory body, if stricter, will apply.

X4.7.1 Temperature Range, operating: 5 to 40ºC.
X4.7.2 Humidity, operating (5 to 40ºC): 15 to 80 % relative humidity.
X4.7.3 Vibration, operating random: 0.2 g for 5- to 100-Hz survival random: 2 g for 5 to 100 Hz.
X4.7.4 Electromagnetic Compatibility (EMC), to meet CISPR 22 Class B ITE or equivalent.

X5. FAULT TOLERANCE

X5.1 The purpose of fault tolerance is to minimize the impact of hardware or software failures on the network and particularly to prevent the loss of data. The following is a description of several of the methods of backup that may be considered.

X5.2 “Hot Swap” Backup—This allows continuous use while replacing a failed drive.

X5.2.1 Disk Mirroring—This system provides for everything to be written to two disks simultaneously; if the primary disk fails, the standby disk can take over automatically. In this system, both disks are served by a single controller.

X5.2.2 Disk Duplexing—This system provides for everything to be written to two disks simultaneously as in disk mirroring, but each disk has a dedicated controller for an added level of protection.

X5.2.3 RAID 1—This is the same as disk mirroring (see X5.2.1).

X5.2.4 RAID 5—RAID 5 can read and write blocks of information to different disks in an array, and it distributes parity information over all disks in the array. Parity is a mathematical representation of data held in the array.

X5.3 Tape Backup—On-line tape backup is an option for multitasking operating systems. Tape backup does not provide “hot swap” capability, and data must be reentered after a drive failure. Also on-line tape backup may slow the system operation to an unacceptable degree.

X5.3.1 ¼-in. Tape, capacities to about 500 Mbytes.
X5.3.2 Digital Audio Tape (DAT), capacities to about 4 Gbytes (8 Gbytes with data compression).
X5.3.3 Video, 8 technology, capacities to about 5 Gbytes. This is based on 8–track, 8–mm tape cartridges used in video camcorders.

X6. FIXED ANTENNAS

X6.1 Scope—This appendix is intended to provide information of the types of fixed antennas commonly provided for navigation, communication, and collision avoidance.

X6.2 Classes—For purposes of this appendix, the following classes of antennas are considered:

X6.2.1 Omnidirectional Transmitting.
X6.2.2 Omnidirectional Receiving.
X6.2.3 Directional Transmitting.
X6.2.4 Directional Receiving.
X6.2.5 Rotating Transmitting/Receiving.

X6.3 Required Antenna Installations for Ocean Area A3 (Typical):

<table>
<thead>
<tr>
<th>System</th>
<th>Type Antenna</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statcom A and B, suitable for telex, telephony, data and voice communication</td>
<td>Automatic directional transmitting/receiving, 1.5 to 1.65 GHz</td>
</tr>
<tr>
<td>Statcom C, telex only Satnav</td>
<td>Omnidirectional, 1.5 to 1.65 GHz</td>
</tr>
<tr>
<td>X-band radar system</td>
<td>Rotating transmitting/receiving—10 cm</td>
</tr>
<tr>
<td>S-band radar system</td>
<td>Rotating transmitting/receiving—3 cm</td>

X6.5.1 Omnidirectional Antennas.
X6.5.2 Radio Transmitting Antennas:
X6.5.2.1 Wire Antennas:
(a) LF communication, 30 to 300 kHz.
(b) MF communication, 300 kHz to 3 MHz.
(c) Emergency communication, 500 kHz.
X6.5.2.2 Whip and Dipole Antennas:
(a) MF communication, 300 kHz to 3 MHz.
(b) HF communication, 3 to 30 MHz.
(c) VHF communication, 30 to 300 MHz.
(d) UHF communication, 300 MHz to 3 GHz.
(e) Facsimile receiver, 3 to 30 MHz.
X6.5.3 Radio/Television Receiving Antennas:
X6.5.3.1 Wire Antennas:
(a) LF communication, 30 to 300 kHz.
(b) MF communication, 300 kHz to 3 MHz.
(c) Emergency communication, 500 kHz.
X6.5.3.2 Omnidirectional Radio and Television Central Antennas.
X6.5.4 Satellite Communication:
X6.5.4.1 Satcom A and B, telex, telephony, data and voice communication, automatic 1.5 to 1.65 GHz.
X6.5.5 Directional Transmitting/Receiving Antennas:
X6.5.5.1 Satcom C, data and telex only, omnidirectional antenna, 1.5 to 1.65 GHz.
X6.5.6 Navigational Antennas
X6.5.6.1 Hyperbolic Navigation Antennas:
(a) Omega System, 10 kHz.
(b) Loran System, 100 kHz.
(c) Decca System, 84 to 130 kHz.
X6.5.7 Global Positioning System (GPS):
L1 band—1575.42 MHz
L2 band—1227.6 MHz
X6.5.8 Navigational Radar Antennas.
X6.5.9 Rotating Transmitting/Receiver Antenna:
X band navigation radar, 8 to 12 GHz
S band navigation radar, 3 to 4 GHz

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

1. Scope

1.1 The principal content of this guide provides a road map to implement a communication network applicable to ship and marine computer systems by:

1.1.1 Examining the relationship of digital communication protocols as a network technological infrastructure,
1.1.2 Outlining the basic building blocks of network topologies and transmission techniques associated with the implementation of transmission media in a network environment; and,
1.1.3 Identifying operating system and environments.

1.2 Using the Open System Interconnection (OSI) model, which provides a layered approach to network functionality and evaluation, common network communications protocols are identified and characterized in this guide according to lower and upper layer protocols corresponding to their degree and type of functionality.

1.3 Although it is desirable that network users, designers, and administrators recognize and understand every possible networking protocol, it is not possible to know the intimate details of every protocol specification. Accordingly, this guide is not intended to address fully every hardware and software protocol ever developed for commercial use, which spans a period of about 25 years. Instead, the user of this guide will be introduced to a brief overview of the majority of past and present protocols which may comprise a ship or marine internetwork, to include Local Area Networks (LANs), Wide Area Networks (WANs), and related hardware and software that provide such network interoperability and data transfer.

1.4 While this guide provides an understanding of the wide range of communication protocols, the user is recommended to consult the reference material for acquiring a more comprehensive understanding of individual communication protocols. However, by examining the basic functions of protocols and reviewing the protocol characterization criteria identified in this guide, the user will be more apt to understanding other protocols not mentioned or addressed herein.

4 Available from IEEE, 445 Hoes Lane, PO Box 1331, Piscataway, NJ 08854-1331.
3.2 Definitions of Terms Specific to This Standard:

3.2.1 bridge, n—a device that interconnects local or remote networks no matter what network protocol that is, TCP/IP or IPX, are involved. Bridges form a single logical network.

3.2.2 hub, n—a central location for the attachment of cables from nodes and other network components.

3.2.3 internetwork, n—a collection of LANs using different network operating systems that are connected to form a larger network.

3.2.4 LAN (local area network), n—a data communication system consisting of a collection of interconnected computers, sharing applications, data and peripherals.

3.2.5 network operating system (NOS), n—the software for a network that runs in a file server and control access to files and other resources from multiple users.

3.2.6 node(s), n—any intelligent device connected to the network. This includes terminal servers, host computers, and any other devices, such as printers and terminals, that are directly connected to the network.

3.2.7 protocol, n—a standard method of communicating over a network.

3.2.8 repeater, n—a network device that repeats signals from one cable onto one or more other cables, while restoring signal timing and waveforms.

3.2.9 router, n—a device capable of filtering/forwarding packets based upon data link layer information.

3.2.10 server, n—a device that stores data for network users and provides network access to that data.

3.2.11 topology, n—the arrangement of the nodes and connecting hardware that comprises the network.

3.2.12 WAN (wide area network), n—a network using common carrier transmission services for transmission of data over a large geographical area.

4. Significance and Use

4.1 This guide is intended to provide an understanding of the wide range of communication protocols standards, allowing the user to understand better their applicability to shipboard networks and marine platform computerized systems. For computerized networks and systems, communication protocols are necessary for integrating various system devices, providing functionality between dissimilar subnetworks, or for enabling remote connections, either pier side or through geophysical communication technologies.

4.2 The wide variety and scope of digital communication protocol standards adds greatly to the complex decision process for specifying compatible protocols for system applications and related devices for the myriad of potential shipboard systems. However, the user must identify the initial networking requirements, so once the network protocols under evaluation are well understood, the decision process should determine the appropriate network protocols. Therefore, this guide is intended to reduce the complexity involved with protocol selection and implementation.

4.3 Network protocols define an agreed, quantifiable entity, or set of rules, by which user computers, system networks, and internetworking devices communicate and exchange information. Communication protocols specify essential networking guidelines, such as physical interface connections, or data
format and control operations between two communicating computers. Ship and marine digital communication protocol requirements are no different than their land-based networked counterparts. Both require standardized protocol selection, in various protocol categories, including LAN standards, WAN protocols, LAN/WAN protocols, network management, wiring hub configurations/operations, hardware platforms, operating systems, and network applications.

5. Origin of Protocol Development

5.1 Communication protocol standards have been developed or refined through three separate processes, identified as follows:

5.1.1 Defacto Protocol Standards—Acquired widespread use of a popular technique adopted by vendors and developers;
5.1.2 Dejur Protocol Standards—Standards making bodies; and,
5.1.3 Proprietary Protocol Standard—Private corporation-based protocols with limited interoperability.

5.2 The open standards approach is now the norm, which allows multiple protocol networking solutions to be available, and as a result, proprietary protocols are now becoming obsolete.

6. Local Network Interconnection

6.1 The characteristic of a local network is determined primarily by three factors: transmission medium, topology, and medium access control protocol.

6.1.1 The principal technological elements that determine the nature of a local network are the topology and transmission medium of the network. Together, it determines the type of data that may be transmitted, the speed and efficiency of communications, and the type of applications that a network may support.

6.1.2 Interconnecting a set of local networks is referred to as an internetworking. The local networks are interconnected by devices generically called gateways. Gateways provide a communication path so that data can be exchanged between networks.

6.2 Topology—The common topologies used for local networks are star, ring, and bus/tree (see Fig. 1).

6.2.1 Star Topology—In a star topology, a central switching element is used to connect all the nodes in the network. The central element uses circuit switching to establish a dedicated path between two stations wishing to communicate (see Fig. 1).

6.2.2 Ring Topology—The ring topology consists of a closed loop, with each node attached to a repeating element. Data circulate around the ring on a series of point-to-point data links between repeaters. A station wishing to transmit waits for its next turn and then sends data out onto the ring in the form of a packet (see Fig. 1).

6.2.3 Bus/Tree Topology—The bus or tree topology is characterized by the use of a multipoint medium. The bus is simply a special case of the tree, in which there is only one trunk, with no branches. Because all devices share a common communications medium, only one pair of devices on a bus or tree can communicate at a time. A distributed medium access protocol is used to determine which station may transmit (see Fig. 1).

6.3 Internetwork Topology—The common topologies used to support emerging networking topologies requiring the integration of data, video and voice, as well as higher transport bandwidth are backbone, hierarchical, and mesh (see Fig. 2).

6.3.1 Backbone—Backbone configurations are used in networking environments in which local networks are connected over high-speed backbone cables. Bridges and routers are used to manage the data passing between interconnected networks and the backbone (see Fig. 2).

6.3.2 Hierarchical—In the hierarchical configuration, star-configured hubs are wired to a central hub that handles interhub traffic. Routers and Asynchronous Transfer Mode (ATM) technology provide support to traffic intensive network applications requiring the integration of voice, video, and data (see Fig. 2).

6.3.3 Mesh—In mesh configurations, there are at least two pathways to each node. This is a common configuration in emerging high-speed enterprise networks requiring the integration of voice, video, and data. It is composed of internetworking devices, such as bridges, routers, and ATM technology. The internetworking devices provide efficient paths for data to travel from one point to another in this configuration. Mesh networks often are used because of reliability; when one path goes down, another can take over (see Fig. 2).

6.4 Cabling—Cabling falls into the following categories: coax, twisted pair, and fiber.

6.4.1 Coax:

6.4.1.1 Thicknet—The standard Thicknet is IEEE 802.3 10BASE5. It is a 0.4-in. diameter RG 4 50-Ω coaxial cable. It may be up to 500 m in length. A maximum of 100 devices can be attached to this cable.

6.4.1.2 ThinNet—The standard for ThinNet is IEEE 802.3 10BASE2. It is a 0.25-in. diameter RG58/A/U 50-Ω coaxial cable. It can be up to 185 m in length and have a maximum of 30 devices attached to it. Each device normally is attached at 0.5-m increments via a BNC T-connector. However, devices may be attached to an AUI cable and external transceiver.

6.4.2 Twisted Pair:

6.4.2.1 The standard for twisted pair is EIA/TIA-568. It is a 24-AWG telephone wire. The ends of the twisted pair wires are
composed of RJ-45 or RJ-11 telephone-style connectors. Each device connects to a network wiring hub which controls or passes the network signal. There are five category ratings for twisted pair wiring, LVL/CAT-1 through LVL/CAT-5.

6.4.2.2 There are two major types of twisted pair: unshielded twisted pair (UTP) and shielded twisted pair (STP). Environmental surroundings dictate what type of twisted pair is used. If the environment is prone to a high degree of electrical interference, STP is used.

6.4.3 **Optical Fiber**—See Table 1.

6.5 Table 2 provides a generalized comparison of the advantages and disadvantages of the technical characteristics of local networks, using the transmission medium as a frame of reference.

**Service Classes of Local Networks and Bandwidth Networks**—Computer networks that serve as components of a communication network provide support to a large multitude of service classes (see Table 3).

6.5.1 **Local Area Network (LAN)**—The LAN provides services to support a group of interconnected computers to share applications, data, and peripherals. Bandwidth service is from 1 to 10 Mbps.

6.5.2 **High-Speed Local Area Networks (HSLN)**—The HSLN provides a service in the range of 50 Mbps to 1 Gpbs. There are two key applications for HSLN: backend and backbone networks. A backend HSLN main function is to provide high end-to-end throughput between high-speed devices, such as servers and mass storage devices. A backbone HSLN provides a LAN or WAN that interconnects intermediate systems. Fiber optic cables are used as a transmission medium to internetwork topologies.

6.5.3 **Wide Area Network (WAN)**—A network that covers a large geographic area. The differences between WAN and LANs are as follows:

- **Economic**—WAN services are purchased; LANs are owned.
- **Technical**—WANs are made up of point-to-point links; LANs are shared-media.

6.6 **Medium Access Control Protocol**—To facilitate the sharing of the transmission among network stations, a proper medium access control scheme must be implemented to control, coordinate, and supervise the access of user information to and from the shared transmission medium:

- **LAN**—IEEE 802.3, IEEE 802.4, and IEEE 802.5 (CSMA/CD, token bus, and token ring) LAN protocols.

- **HSLN**—IEEE 802.2 (FDDI fiber token ring protocol) or IEEE 802.6 DQDB, ATM.

- **WAN**—X.25 Frame Relay, ATM.

**FIG. 2 Internetwork Topology**
6.7 Internetworking (Gateways and Routers)—
Internetworking is the interconnection and interoperability of small-size local networks into existing networks. A local network should have the capability to support multiple protocols and allow difference environments to operate in parallel. Internetworking devices available for these services are Routers and Gateways.

6.7.1 Routers are devices that implement the network service. Routers are required to support multiple protocol stacks, each with its own routing protocols, and to allow these different environments to operate in parallel.

6.7.2 Gateways are applications specific that connect different architectures. It also provides translation services between different protocols.

6.8 Types of LANs—LANs are descriptive in their configuration at two levels: administrative relationship between nodes (stations) and physical and logical relationship among nodes.

6.8.1 Administrative Relationship Between Nodes (Station)—LANs are divided into server-based and peer-to-peer LANs. Server-based LAN (client server) controls access to some resource, such as a hard disk or printer, and serves as a host for the workstations connected to the server. A workstation request services, such as access to fields or programs on the hard disk or use of a printer, from a server.

6.8.1.1 Servers run the network operating system (NOS) software; workstations run client software that manages the communication between the workstation and the network.

6.8.1.2 Peer-to-peer LANs involve direct communications between computing devices without a dedicated server.

6.8.2 Physical and Logical Relationship Among Nodes—This has to do with the manner in how data is transmitted over a network. The physical is concerned with the topology, that is, bus, ring, or star, and logical refers to the method of data transport that is Ethernet, Token Ring, FDDI, ATM, and so forth.

6.9 Network Operating System (NOS)—The NOS runs on a server and is responsible for processing requests from workstations, for maintaining the network, and for controlling the services and devices available to users. An NOS may replace the native operating system or run as a program on top of the native operating system. Current NOS available are: NOVELL Netware, WINDOWS NT, LANtastic, BANYAN, IBM LAN Server, LAN Manager, AppleShare/AppleTalk.

6.10 Operating System (OS)—Operating systems bring together disparate computing resources and present the user with more convenient abstractions. These resources include devices for processing, storing, and transmitting information:

6.10.1 DOS (Disk Operating System)—Single-user operating system for the personal computer (PC).

6.10.2 Windows 95/NT—Microsoft windows product replacing Windows 3.1 and Windows for Workgroup 3.11. It provides system monitor utilities, remote access, network e-mail, fax capabilities, and file-and printer-sharing for both Windows-based and Netware-based clients.

6.10.3 OS/2—A multicasting operating system originally developed by IBM and Microsoft for use with Intel’s microprocessor and IBM’s Personal System/2 (PS/2) computers.

6.10.4 MAC OS—Apple’s Mac operating system.

6.10.5 UNIX—A multitasking, multiuser operating system developed by AT&T. This means that more than one user can use the same computer (programs, file system, memory, CPU) by logging in off of different ports (serial, Ethernet, Internet, and so forth).

6.11 Operating Environments—Operating environments provide computing flexibility and power to have more than one application active at the same time. They allow users to activate and switch several applications simultaneously.

6.11.1 Windows 3.1—This program provides an environment for running 16-bit Windows and DOS applications. It also supports multimedia, true-type fonts, compound documents (OLE), as well as drag-and-stop capabilities.

6.11.2 Windows for Workgroups—This program is a LAN-capable version of MS Windows 3.1 environment providing integrated file sharing, electronic mail (Microsoft Mail), and workgroup scheduling (Schedule +) capabilities. Windows for Workgroups 3.11 also supports 32-bit disk and file access.
6.11.3 Windows 95/NT—This program provides utilities, protocols, and services for a LAN environment running client software with support for Windows, Windows NT Workstation, Windows for Workgroups, MS-DOS, Macintosh, OS/2, and UNIX.

6.11.4 X Window System—A network-based windowing system. It provides an application interface for graphic window displays.

7. OSI Layers of Functionality

7.1 The OSI is a reference model put forth by the International Standards Organization (ISO) for communication between computer equipment and networks partitions computer communication functions into seven layers. Each layer provides a certain kind of service to the next higher layer. This service is provided by communicating with the peer entity in the same layer of the remote host using the service provided by the next lower layer. This model explains what each layer does. The model is often used to explain a suite of protocols, not just OSI, to allow computers to share resources across a network (see Table 4).

7.2 The content of each of the first four layers is dictated by the parameters of the network technology, and the upper three by the demands of the application user. As shown in Fig. 3, the lowest four layers, which are physical (1), data link (2), network (3), and transport (4), correspond roughly to protocols used in all networks. Physical distinguishes individual (0,1) bits, data link allows reliable transmission of groups of bits between adjacent computers, network provides safe routing data packets between distant source and destination computers, and transport lets programs running on different computers exchange sequences of possibly long messages.

7.3 The bottom three layers are implemented by communications carrier hardware or by LAN interfaces. Transport software runs on user computers. The highest three layers, session (5), presentation (6), and application (7), are intended to serve the needs of the application or application-specific elements.

7.4 For WANs, the intermediate-node routing function, network layer, is important, but media access is simple, usually a maker of making a leased, dial-up connection or satellite. Conversely, for LANs and MANs, no routing decisions need be made, and the network layer is essentially absent, although the multiaccess protocol can become quite sophisticated.

8. Layers of Interconnection

8.1 The OSI model allows networks to be interconnected at Layers 1 through 3 and 7. Interconnections between LANs and WANs usually occur at Layers 2 through 4 except for protocol conversion between specific applications, such as electronic mail which occur at Layer 7. A generic LAN/WAN interconnection function must operate at the lower OSI layers.

8.2 Model Structure—The OSI presents an abstract reference model to describe the computer communications. A layering techniques is used to divide the functions in to distinct yet connected layers. The seven layers can be partitioned into two main infrastructures, the lowest three layers provide internetworking services and the upper four layers are the users of these services. The upper layers, together, provide common network application services. One of the layers, the Transport Layer (4), serves as the boundary between the network-specific elements and the application-specific elements (see Fig. 4): 8.2.1 Lower layer infrastructure providing the end-to-end services responsible for data transfer.

8.2.2 Upper layer infrastructure providing the application services responsible for information transfer.

8.2.3 Each layer provides a well-defined function. Conceptually, these layers can be considered as performing one of two functions:

8.2.3.1 Network-Dependent Functions, lower layer.

8.2.3.2 Application-Oriented Functions, upper layer.

8.2.4 Thus when interconnecting networks, communication services are characterized by the following:

8.2.4.1 Data Link Protocol—Ethernet, Token Ring, FDDI, and ATM.

8.2.4.2 Network Protocol—IP, IPX, TCP, IPVINES, NETBIOS, and NETBEUL.

8.2.4.3 Higher Level Protocol (NOS)—Netware, Appletalk, Banyan VINES, Windows NT, IBM OS/2 LAN Manager, and so forth.

8.2.5 A canonical form of a layered communication protocol is illustrated in Fig. 5.

9.1 The characterization of common network protocols based on the layers of the OSI reference model provides a comparative technique to separate the various communication protocols into two categories. This perspective characterizes communication protocols based on their functionality and operations. By examining the seven layers of the OSI reference model, a lower and upper layer grouping for protocol characterization is developed to provide a better understanding for subsequent protocol selection for shipboard systems. This upper and lower layer characterization perspective is not perfect. Some communications protocols do not correspond exactly to the OSI layers in terms of functionality, while another popular protocol suite similar to the entire OSI network model does not fully correspond exactly to all the OSI layers.

9.2 The communication protocols described in this guide, which are based on the two lowest layers, the data link and physical layers of the OSI model, may differ among themselves with respect to levels of maturity and degree of commercial implementation. These lower layer protocols consists of a mixture of LAN and WAN technology protocols.

9.3 Upper layer protocols, in contrast, are often found to be families, or suites of protocols, developed as total networking solutions which mainly were developed as proprietary, corporate-based networking schemes. In addition, many upper layer protocols support integration with other upper and lower level protocols, enhancing their popularity and implementation possibilities with dissimilar protocols. Several of these protocols described in this guide were developed by standard groups, although sometimes only portions of the “dejure” protocol suites have been adopted commercially for certain applications.

10. Lower Level Protocols

10.1 The lower level protocols are the standards, specifications, and physical characteristics associated with the implementation of transmission media in a local network environment.

10.1.1 Ethernet—Ethernet is based on IEEE 802.3 standards. The standards that define IEEE 802.3 (see Table 5) networks have been given names that follow the form “s type 1.” The S refers to the speed of the network in Mbps, type is BASE for baseband and BROAD for broadband, and I refers to the maximum segment length in 100–m multiples. Table 5 shows the operating characteristics of three currently defined IEEE 802.3 networks to Ethernet.

10.1.2 Token Ring—Token ring is based on IEEE 802.5 standards. It can be either a 4- or 16-Mbps LAN. Instead of connecting to HUB, the lobe runs connect to either a multi-station access unit (MAU) or cable access unit (CAU). A maximum of 260 devices can be connected to a MAU or CAU star-wired ring, depending on the type of cable interface. IBM supports up to 260 devices attached to a MAU via the IBM cabling. With UTP, only 72 can be connected to a MAU and 144 to a CAU. See Table 6.

10.1.3 Fiber Distributed Data Interface—FDDI is based on IEEE 802.8 standards. FDDI networks operate at 100 Mbps over either fiber optic or twisted pair transmission media, using a counter-rotating redundant, dual-ring topology. The total length of the dual ring may not exceed 100 km (or 200 KM when wrapped or connected during a fault condition), with a maximum of 500 attached stations.

10.1.4 X.25 (see Fig. 6)—X.25 is a packet-switched network not transparent to attached stations, even during the data transfer phase. At a minimum, the network layer protocol must provide a service for transferring data between stations. This service may be either a virtual-circuit service (connection-oriented) or a datagram service (connectionless). Most public

* Based on IEEE 802.3 (CSMA/CD).
networks provide a virtual-circuit service. X.25 encompasses the first three layers of the OSI model.

10.1.4.1 Layer 1—The physical layer is concerned with electrical or signalling. It includes standards, such as V.35, X.21(BIS), EIA232C.

10.1.4.2 Layer 2—The data link layer manages the transfer of data units called frames from one open system to another. The data link layer specified in X.25 is called LAP-B (Link Access Procedure Balanced).

10.1.4.3 Layer 3—The X.25 Packet Level Protocol (PLP) provides network-routing functions and the multiplexing of simultaneous logical connections over a single physical connection.

10.1.5 Frame Relay—Frame relay is a connection-oriented, fast-packet data service, conceptually similar to X.25. Whereas X.25 has three protocol layers and provides a guaranteed, virtual circuit packet delivery service, frame relay has only two layers of protocol (physical and data link layer) and relies on higher-layer protocols for end-to-end message assurance (see Fig. 6).

10.1.5.1 Frame relay is data link protocol. Frame relay service is viewed as one of the more versatile packet-switched technologies available for efficiently linking geographically separate organizations. Frame relay generally is deployed in larger internetworks. Table 8 shows the TCP/IP layers in relation to the seven layer OSI model.

11. Upper Layer Protocols

11.1 Upper layer protocols provide access to and control of the network environment, its applications, and data. The lower layers are used to exchange information.

11.2 ISO Architecture (see Table 7)—The ISO protocols are intended to standardize the by-products of network software and hardware development. The seven-layer ISO architectural model includes physical and data link layers that allow other protocol stacks to exist on the same media. OSI protocols include IEEE 802.2, 802.3, 803.5, ANSI FDDI X.21, V.35, X.25, and so forth. OSI also offers both a connectionless and connection-oriented network layer service.

11.3 TCP/IP—TCP/IP is a protocol suite. It is termed a suite because it is a family of protocols that can be used independently of each other. TCP/IP is not dependent on any particular physical connection. It was designed to connect subnetworks to larger internetworks. Table 7 shows the TCP/IP layers in relation to the seven layer OSI model.

11.3.1 TCP is a connection-oriented transport layer protocol that uses the connectionless services of IP to ensure the reliable delivery of data. Connection-oriented services establish link between two devices on a LAN. This link stays active for the length of a data transmission and can be closed when the transfer is furnished. With connectionless services, there is no requirement to establish a link between a source and destination device before data transmission can begin. Connectionless services are capable of sending data packets to multiple destinations, while connection-oriented services cannot.

11.3.2 TCP/IP provides important services, such as file transfer, e-mail, and remote login across a large number of distributed client and server systems. TCP/IP was introduced with UNIX, and then it was later incorporated into the IBM environment.

11.3.3 To ensure that multivendor, multiplatform systems could communicate, the original design was based on open system standards. Because of this design, TCP/IP is platform independent in that it operates in a similar manner no matter what the platform. This is synonymous with interoperability, a key strategy for choosing and using protocols.

11.4 **NETWARE IPX/SPX**—Novell Netware protocols comply to the OSI model. The upper five layers provide file and printer sharing and support for various applications, such as electronic mail transfer, database access, and other dedicated NOS services (that is SNA, TCP/IP, AppleTalk, and OSI). The Internetwork Packet Exchange (IPX) (see Table 9) is a Netware protocol used to move data across a Novell network. The IPX packet deals directly with routers to move data across Novell NetWare Internetworks. IPX is a result of Novell’s efforts to add new services and features to the original Xerox XNS protocols.

11.4.1 IPX uses the Sequenced Packet Exchange (SPX) protocol to provide applications with reliable, connection-oriented data transport service. In the OSI model, IPX conforms to the network layer and SPX the transport layer.

11.5 **Systems Network Architecture (SNA)**—SNA is IBM’s proprietary networking protocol. SNA was designed to operate at the data link layer of the OSI model. The SNA network is a host-terminal environment because the mainframe acts as a host system, which is accessed by display devices called terminals.

11.6 **Advanced Peer-to-Peer Networking (APPN)**—APPN is IBM’s proprietary networking protocol. It is an enhancement to SNA to provide support for distributed applications in IBM networks, such as mainframes, AS/400s, and PS/2s. APPN enables direct communication between users anywhere on the network, a feature SNA could not provide. Much like TCP/IP, APPN resides at Layers 3 and 4 of the OSI model, providing network and transport functionality.

11.7 **Apple Talk**—AppleTalk is an OSI-based, CSMA/CD LAN technology from Apple. It supports Apple’s proprietary LocalTalk access method, as well as Ethernet (EtherTalk), and token-ring (TokenTalk). The AppleTalk network manager and the LocalTalk access method are built into all MACs and Laser Writer printers, as well as many third-party devices. AppleTalk can run on PCs, VAXs, and UNIX workstations.

11.7.1 LocalTalk is Apple’s LAN access method that uses twisted pair wiring and transmits at 230.4 Kbps. It runs under AppleTalk (see Table 10) and uses a daisy chain topology that connects up to 32 devices at a distance of up to about 1000 ft. LocalTalk can be configured to work in bus, passive, star, and active star topologies.

11.7.2 At Layer 3, the Datagram Delivery Protocol (DDP) provides a connectionless datagram services. At Layer 4, in the AppleTalk architecture, the Name Binding Protocol (NBP) provides name-to-address association. Routing table content is provided by the Routing Table Maintenance Protocol. At Layer 5, the Zone Information Protocol (ZIP) provides means of localizing broadcast traffic.

11.8 **XEROX Network Systems (XNS)** (see Table 11)—The XNS architecture makes two basic assumptions about its users: the Internetwork's underlying LAN technology is Ethernet, and multiple Ethernets exists. The XNS protocol implementation provides five level layers and corresponds closely to the OSI model.

11.8.1 XNS Level 0 defines the transmission media protocols that provide the physical mechanism for packet transport.

11.8.2 XNS Level 1 defines the destination of the datagram (packet), and how it will get there. The Internetwork Datagram Protocol (IDP) is defined, as well as an addressing scheme to designate the various networks, hosts, and sockets through which that packet will originate, traverse, or terminate.

11.8.3 XNS Level 2 provides structures for the stream of datagrams. This level deals with the multitude of issues, such as sequencing, flow control, and retransmissions that are required of the OSI Transport Layer.

11.8.4 XNS Level 3 provides structures for the actual data that was transmitted and also controls various processes. As such, Level 3 covers the OSI session and presentation layers, and is designated the control protocols. XNS Level 4 deals with the various application protocols, similar to the OSI model.

11.9 DNAs (Digital Network Architecture) DECNet/OSI—DNA is the architecture, or master plan, for networking. DECNet/OST is an implementation of the architecture that is compliant with the ISO’s Open System Interconnection (OSI) Model in both number of layers, as well as layer functionality (see Table 12). DECNet is a proprietary Digital Equipment Corporation (DEC) Protocol. DECNet is a host-to-host (peer-to-peer) communication network. DECNet supports both connectionless and connection-oriented network layers. Both network layers are implemented by OSI protocols.

11.10 Local Area Transport (LAT)—LAT is a proprietary Digital Equipment Corporation (DEC) protocol (see Table 13). LAT is a terminal-to-host, or terminal I/O network on an Ethernet. LAT is a lean and mean protocol stack whose only purpose in life is to move terminal I/O as fast as possible between host and terminals and printers. LAT approximately implements Layers 3, 4, and 5. LAT is nonroutable protocol stack, which can only exist on the Ethernet implementation of Layers 1 and 2. LAT is implemented on VAXen, Alpha AXPs, in terminal servers, such as DECservers, and PCs and Macintoshes running PATHWORKS.

11.11 NetBEUI (Microsoft—proprietary)—NetBIOS Extended User Interface (NetBEUI) is the native network protocol used by Microsoft’s Windows NT and Windows 95. NetBEUI is an enhanced version of NetBIOS protocol used by a network operating system (NOS), such as LAN Manager and LAN server. Systems that use NetBEUI, such as Windows NT, can communicate with other Windows NT systems, as well as workstations running Windows for Workgroups.

11.12 NetBIOS—NetBIOS (Network Basic/Input System) is a network protocol designed exclusively for use in LANs. NetBIOS, along with its API, provide support of peer-to-peer network functions and a simple interface for writing network applications. There is no routing layer in NetBIOS. This means that NetBIOS cannot provide internetworking capabilities. Other protocols, such as IP or IPX must be used for internetworking. NetBIOS provides session and transport services (Layers 4 and 5 of the OSI model). This NetBIOS often is used to establish a connection between devices.

12. Fault Tolerance in Communication Networks

12.1 Fault tolerance is achieved using one or more of several forms of redundancy, which is simply the addition of information, resources, or time beyond what is needed for a normal system operation. The redundancy can take one of several forms, including hardware redundancy, software redundancy, information redundancy, and time redundancy.

13. Implementing a Communication Network

13.1 There are many documents and articles that discuss actual network design. Network designers have a definite preference for standard-based solutions, including those for media, protocols, and topologies. Standard-based networking solutions have the aura of optimally conceived technology and the promise of low (commodity) cost and multivendor available networking equipment using common silicon-based implementations. Standards not only imply the preceding desirable features, but also, at least theoretically, guarantee interoperability of equipment from different vendors.

13.2 Topology Selection Decision Tree—See Fig. 7.

13.3 Network Environment Selection Decision Tree—See Fig. 8, Fig. 9, and Fig. 10.

13.4 Internetworking (LAN-to-LAN or LAN-to-WAN):

13.4.1 Identify transport protocols present or supported by LAN-to-LAN or LAN-to-WAN internetwork.

13.4.2 Is the transport protocol(s) identified in 13.3 proprietary?

13.4.3 Identify a common denominator transport protocol to facilitate internetworking: RECOMMENDED: TCP/IP.
13.4.4 Identify basic services to be provided: FILE TRANSFER, ELECTRONIC MAIL, ROUTING, REMOTE ACCESS (Terminal Emulation).

13.4.5 Verify interoperability of NOS: Yes–Use router; No–Use gateway.

3. Terminology

3.1 Definitions:

3.1.1 absolute contaminant removal rating—the smallest size of contaminant as defined in ARP 901 that the filter will retain with 100 % efficiency by weight.
3.1.2 bubble point—the pressure differential across a submerged filter element required to produce a visible and steady stream of air bubbles. Correlation between bubble point and contaminant removal capability provides an economical means to test for contaminant removal capability on a production basis. The bubble point indicates the maximum pore size of the filter media under static conditions.
3.1.3 bubble-tight—no visible leakage over a 3-min period using either water submersion or the application of bubble fluid for detection.
3.1.4 clean filter element pressure drop—the pressure drop across the filter element when it is new or uncontaminated.
3.1.5 cleanable filter element—a filter element that, after being contaminated to its dirt-holding capacity (contaminated filter element pressure drop), can be restored by cleaning to operational condition and with a pressure drop not exceeding the required clean filter element pressure drop.
3.1.6 contaminant removal rating—this is a measure of the size of contaminants that the filter can remove from the flow stream.
3.1.7 contaminated filter element pressure drop—the pressure drop across the filter element when it is contaminated to the point where cleaning or replacement is required.
3.1.8 differential pressure indicator actuation pressure—the pressure drop across the filter element at which the differential pressure indicator actuates.

3.1.9 disposable filter element—a filter element that, after being contaminated to its dirt-holding capacity (contaminated filter element pressure drop), cannot be restored to operational conditions and thereafter should be replaced.

3.1.10 external leakage—leakage that escapes to atmosphere.

3.1.11 filter element bypass full-flow differential pressure—the pressure drop across the filter element at which the filter bypass is passing the full-flow rating of the filter.

3.1.12 filter element bypass reseat differential pressure—the pressure drop across the filter element at which the filter bypass reseats after passing the full-flow rating of the filter.

3.1.13 filter element bypass set differential pressure—the pressure drop across the filter element at which the filter bypass opens.

3.1.14 filter element collapse strength—the maximum pressure drop or differential across the filter element that the element must withstand without collapse, damage, or impairment of performance capabilities.

3.1.15 filter element contaminant-holding capacity—also commonly termed “dirt capacity.” The amount of a contaminant, expressed in weight, that the element can hold when its resistance to flow causes a pressure drop equal to the contaminated filter element pressure drop.

3.1.16 filter element pressure drop—the pressure drop across the filter element.

3.1.17 filter housing pressure drop—the pressure drop accounted for by the filter housing.

3.1.18 filter pressure drop—the pressure drop across the entire filter (element and housing) at any given flow rate of the service fluid (air or nitrogen).

3.1.19 flow capacity—the maximum flow rate that the filter is required to pass.

3.1.20 hydrostatic shell test pressure—the hydrostatic test pressure that the filter is required to withstand without damage. The filter must be capable of meeting all performance requirements after the shell test pressure has been removed.

3.1.21 media migration—any material released into the flow stream by the filter media and its materials of construction. This term refers to the tendency of the filter media or “built-in” contamination, such as, welding scale, metal particles, or air-borne dust combined with the media during its manufacture, to leave the filter and shed or migrate into the flow stream.

3.1.22 nominal contaminant removal rating—the smallest size of contaminant as defined in ARP 901 that the filter will retain with 98% efficiency by weight.

3.1.23 operating pressure—the pressure within the filter during service.

3.1.24 pressure ratings—the pressure rating of the filter shall be defined in the documents listed in Table 1. The pressure rating for a filter is the maximum allowable working (service) pressure at 100°F (38°C).

*aFor union inlet and outlet connections, only the pertinent dimensions listed in the applicable documents (military specification or NAVESA requirements) shall apply. The filter shall be supplied with the thread pieces only, without the tail pieces and union nuts.

4. Classification

4.1 Filters shall be of the following types, compositions, styles, pressure ratings, sizes, end connections, and contamination removal ratings, as specified in Section 5.

4.1.1 Filter Element Type:

4.1.1.1 Type I—Disposable.

4.1.1.2 Type II—Cleanable.

4.1.2 Filter Element Bypass Composition:

4.1.2.1 Composition A: with bypass.

4.1.2.2 Composition B: without bypass.

4.1.3 Filter Element Differential Indicator Style:

4.1.3.1 Style I: with differential pressure indicator.

4.1.3.2 Style II: without differential pressure indicator.

4.2 Pressure Ratings—Filters shall have pressure ratings selected from those listed in Table 1 and specified in Section 5. The pressure rating selected shall be the same for both the filter inlet and outlet.

4.3 Size—Filter sizes shall be ¼ NPS (13.5 mm), ½ NPS (21.3 mm), ¾ NPS (26.9 mm), 1 NPS (33.7 mm), 1¼ NPS (42.4 mm), 1½ NPS (48.3 mm), and 2 NPS (60.3 mm) or as specified in Section 5 (see Table 2).

4.4 End Connections—Filters shall have inlet and outlet end connections selected from those listed in Table 1 and specified in Section 5. Inlet and outlet connections shall be identical.

4.5 Contamination Removal Ratings—Filters shall have contamination removal ratings selected from the following three categories: 20 µm nominal/50 µm absolute, 5 µm nominal/18 µm absolute, and 0.4 µm nominal/5 µm absolute. The contamination rating selected shall be specified in Section 5.

5. Ordering Information

5.1 Ordering documentation for filters under the specification shall include the following information, as required, to describe the equipment adequately.

5.1.1 ASTM designation and year of issue,
5.1.2 Title, number, and date of this specification,
5.1.3 Filter element type (see 4.1.1),
5.1.4 Filter element bypass composition (see 4.1.2),
5.1.5 Filter element differential pressure indicator style (see 4.1.3),
5.1.6 Filter pressure rating (see 4.2),
5.1.7 Size (see 4.3),
5.1.8 End connections (see 4.4),
5.1.9 Contaminant removal rating, absolute/nominal (see 4.5),
5.1.10 Maximum filter operating pressure,
5.1.11 Flow capacity required (see 7.1, S1.3),
5.1.12 Supplementary requirements, if any ($1.0 through $4.0), and
5.1.13 Maximum vibration frequency and amplitude, if other than specified (see S1.8).

6. Filter Design and Construction

6.1 Filters shall incorporate the design features specified in 6.1.1-6.1.6.

6.1.1 Materials of Construction—Materials shall be 300 series corrosion-resistant steel (SS304, 304L, 316, or 316L), or other materials selected to provide compatibility with the line medium, weldability, and corrosion resistance without requiring painting, coating, or plating. The filter body and the filter bowl shall be weld repairable. Materials for contacting parts shall be selected to minimize electrolytic corrosion and galling.

6.1.2 Design Construction Requirements:

6.1.2.1 General Construction—The filter shall have a bolted flanged body and filter bowl to expedite removal of the filter element for cleaning or replacement.

6.1.2.2 Collapse Strength—The filter element shall be capable of withstanding a differential pressure equal to the maximum inlet pressure rating without structural degradation.

6.1.2.3 Automatic Bypass—When specified (see 5.1.4), the filter assembly shall incorporate an automatic bypass feature to bypass system fluid automatically around the filter element in the event of excessive flow restriction through the filter element. The automatic bypass shall be set in accordance with Table 3 and shall have a capacity equal to or greater than that of a clean filter assembly.

6.1.2.4 Filter Element Installation—Positive means shall prevent any play or looseness of the filter element in service and prevent cocking or misalignment during installation.

6.1.2.5 Filter Element Flow Direction—The filter element flow direction shall be from the outside to the inside surface of the element.

6.1.2.6 Cleanability—Cleanable filter elements shall be cleanable and reusable by means of scrubbing and washing the outside surface with detergent and tap water and blowing through with compressed air not exceeding 30-psig (207-kPa gage pressure). Once cleaned, the element shall be capable of meeting the requirements for a new element. Cleanable filter elements shall not be adversely affected by immersion in water and shall be capable of meeting the above criteria for not less than five cleaning and reuse cycles.

6.1.2.7 Differential Pressure Indicator—When specified (see 5.1.5), the filter body shall incorporate a non-electrical, “pop up” differential pressure indicator which senses the pressure drop across the element and actuates in accordance with Table 3. Once actuated, a red indicator button shall remain up until manually reset.

6.1.2.8 O-Ring Locations—O-rings in face-seal applications shall have the grooves located in the lower members to simplify assembly.

6.1.2.9 Pressure Envelope—The hydrostatic shell test pressures shall be 1.5 times the filter rated pressure at 100°F (38°C).

6.1.2.10 Connections—The inlet and outlet end connections of the filter shall be as specified in Table 1. Any exposed threads shall be protected by plastic caps for shipping.

6.1.2.11 Port Configuration—The filter body shall have in-line inlet and outlet end connections for installation into the piping system.

6.1.2.12 Pressure Lines—All pressure lines in the filter shall be internally ported.

6.1.2.13 Accessibility—The filter shall be fully and easily accessible for cleaning or repair without removal of the filter body from the line.

6.1.2.14 Threads—Threads shall be as specified in ASME B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used.

6.1.2.15 Interchangeability—The entire filter, including all associated piece parts, shall have part number identity and shall be replaceable from stock or the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s

**NOTE**—Percentages shown above shall read as percent of the operating pressure of the filter (see 3.1.23 and 5.1.10).
part number shall be directly interchangeable with each other with respect to installation (physical) and performance (function). Physically interchangeable assemblies, components, and parts are those that are capable of being readily installed, removed, or replaced without alteration, misalignment, or damage to parts being installed or adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.1.2.16 Nonmetallic Element Interchangeability—Nonmetallic elements, including but not limited to, cushions and O-rings, shall be treated as separately identified and readily replaceable parts.

6.1.2.17 Pressure Gage Ports—The filter shall be provided with threaded gage connection ports to permit attachment of pressure gages for sensing the inlet and outlet pressures. The gage connections shall be located to measure the pressure differential across the filter element accurately.

6.1.2.18 Springs—Any spring incorporated in the filter shall not be compressed solid during operation. Spring ends shall be squared and ground. Engagement or disengagement of parts against spring compression shall not be required.

6.1.3 Maintainability—The filter shall permit direct access for disassembly, repair, and reassembly of the filter element and all internal working parts and subassemblies when mounted for operation in the system. Maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified and shall be supplied as part of the filter.

6.1.4 Reversibility—The filter element, and all other parts in the filter, shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.1.5 Adjustments—There shall be no adjustments required in the filter during or after assembly other than the set points of a differential pressure indicator or an automatic bypass valve or both, where applicable.

6.1.6 Reliability—Except for cleaning or replacement of the filter element, periodic maintenance of the filter or any of its components shall not be required. There shall be no postassembly lubrication required.

7. Performance

7.1 Filters shall meet the performance requirements of 7.1.1-7.1.8.

7.1.1 Contaminant Removal Rating—The filter shall be capable of the levels of contaminant removal specified in the ordering information (see 4.5 and Section 5).

7.1.2 Flow Capacity—The flow capacity of the filter shall be as specified in 5.1.11 in standard cubic feet per minute (cubic metre per second) [at 60°F (16°C) and 14.7 psia (101 kPa absolute)]. The filter shall meet the specified maximum flow capacity, or any intermediate capacity, and shall operate while providing the specified filter contaminant removal rating. If an automatic bypass is specified (see 5.1.4), it shall also meet the flow capacity requirements of the filter.

7.1.3 External Leakage—Filter external leakage shall be bubble-tight at operating pressure conditions over a 3-min period.

7.1.4 Filter Element Contaminant-Holding Capacity—Solid particulate contaminant (dirt) holding capacity shall be as specified in Table 2.

7.1.5 Pressure Drop—The maximum allowable filter element clean and contaminated pressure drops shall be as specified in Table 3.

7.1.6 Differential Pressure (ΔP) Indicator Actuation Pressure—The pressure drop across the filter element at which the differential pressure indicator, where applicable, actuates shall be as specified in Table 3.

7.1.7 Filter Element Bypass Set, Full-Flow, and Reseat Differential Pressures—The set, full-flow, and reseat differential pressures of an automatic filter element bypass, where applicable, shall be as specified in Table 3.

7.1.8 Media Migration—There shall be no media migration.

8. Tests Required

8.1 Each filter shall pass the tests outlined in 8.1.1-8.1.4.

8.1.1 Visual Examination—The filter shall be examined visually to determine conformance with the ordering data and workmanship without disassembly.

8.1.2 Hydrostatic Shell Test—The filter shall be hydrostatically tested by applying pressure equal to 1.5 times the 100°F (38°C) rated pressure to the inlet and outlet ports, respectively, to check the structural integrity of the filter. The filter element may be removed for this test. Pressure shall be applied for a minimum of 3 min. Air or nitrogen gas may be used in lieu of water providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible gas. There shall be no external leakage, permanent distortion, or structural failure.

8.1.3 External Leakage Test—Air shall be applied at rated pressure to the filter. External leakage shall be checked using bubble fluid or by submerging the filter in water. There shall be no visible external leakage over a 3-min period.

8.1.4 Bubble Point Test—The filter element shall be tested to determine the initial bubble point. The bubble point test shall be performed in accordance with the procedure specified in ARP 901. To ensure the correct nominal contaminant removal rating and absolute contaminant removal rating, acceptance criterion shall have been previously established for the particular filter design being tested by an empirical correlation of the results of bubble point testing with actual particle retention testing as outlined in ARP 901.

9. Marking

9.1 Identification Plate—An identification plate of corrosion-resistant metal in accordance with Specification F 992: Types I, II, III, or IV shall be permanently attached to the filter and shall include the following information (some or all information may instead be stamped or etched directly on the filter body):

9.1.1 Manufacturer’s name,
9.1.2 ASTM designation and year of issue,
9.1.3 Operating conditions (inlet pressure and flow capacity),
9.1.4 Manufacturer’s model/part number,
9.1.5 Pressure rating,
9.1.6 Contamination removal rating (nominal/absolute in micrometre),
9.1.7 Replacement element part number,
9.1.8 Flow direction, if applicable.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied. This system shall also ensure that all filters will perform in a similar manner to those representative filters subjected to original testing.

10.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the filters in the manufacturer’s plant to the extent specified on the purchase order.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1.0, S2.0, S3.0, or S4.0 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirements of the specification itself.

S1. Supplemental Tests

S1.1 Supplemental tests shall be conducted at a facility satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.2 through S1.11 and delineated in the ordering data. The tests may be conducted on representative filter sizes and pressure classes to qualify all sizes and pressure classes of filters, provided the filters are of the same type and design. Evidence of prior approval of these tests is acceptable.

S1.2 Element Collapse Test—Apply a pressure differential across the filter element equal to the pressure rating specified in Section 5 for 3 min. There shall be no structural damage to the filter element.

S1.3 Cleanability Test—The filter shall be subjected to sufficient contamination so that flow requirements cannot be met. It shall then be cleaned by the methods specified (see 6.1.2.6) to demonstrate cleanability. After cleaning, the element shall be capable of meeting the applicable flow and pressure drop criteria (see S1.5).

S1.4 Flow Capacity/Clean Filter Element Pressure Drop Test—Apply an inlet pressure equal to the maximum operating pressure of the filter (see 3.1.23 and 5.1.11). Flow shall be increased to the flow capacity of the filter. Pressure drop shall not exceed the allowable clean filter element pressure drop specified in Table 3. If the clean filter element pressure drop has been previously determined at a different inlet pressure, this test may be waived where calculations or previous testing are provided which verify an acceptable clean filter element pressure drop at the maximum operating pressure.

S1.5 Differential Pressure Indicator Actuation Pressure Test—Differential pressure across the filter element shall be increased until the differential pressure indicator actuates. The actuation pressure shall be as specified in Table 3. Once actuated, the red button shall remain in the up position until manually reset.

S1.6 Automatic Bypass Valve Set Differential Pressure Test—Differential pressure across the filter element shall be further increased until the automatic bypass valve opens. Differential pressure shall be further increased until the automatic bypass valve is fully open. Differential pressure shall then decreased until the automatic bypass valve reseats. The automatic bypass valve shall lift initially, then lift to pass the full-flow capacity, and reseat within the limits specified in Table 3. There shall be evidence of operational instability or damage.

S1.7 Seat Tightness Test—The differential pressure across the automatic bypass valve shall be increased to 95 % of its set pressure. The automatic bypass valve shall be bubble-tight (no visible evidence of leakage over a 3-min period using bubble fluid for detection or submerging a line from the outlet under water).

S1.8 Shock Test—The filter shall be subjected to and meet the high-impact shock tests for Grade A, Class I as specified in MIL-S-901 pressurized with water, air, or nitrogen to the maximum operating pressure. There shall be no structural damage to the filter. There shall be no degradation to the performance capability of the filters.

S1.9 Vibration Test—The filter shall be vibration tested in accordance with Type I of MIL-STD-167-1 pressurized with air or nitrogen to the maximum operating pressure. At frequencies up to and including 33 Hz (unless otherwise specified in the ordering information, Section 5), there shall be no resonance in the range of frequency tested. There shall be no structural damage or degradation to the performance capability of the filter.

S1.10 Noise Test—The filter shall be tested for airborne noise in accordance with MIL-STD-740-1. The noise (sound pressure level) shall not exceed 85 dBA observed at 1-m distance from the filter.

S1.11 Posttest Examination—The filter shall be disassembled and examined for any evidence of excessive wear, degradation, or impending damage or breakage.

S2. Technical Data Requirements

S2.1 Drawings—Assembly drawings or catalog sheets of the filter that clearly depict design shall be provided. The following shall also be included as part of, or in addition to, the drawing or catalog content:

S2.1.1 Bill of material listing specification, grade, condition, and any other data required to identify fully the properties
of the materials proposed. This shall include identifications, material and size designations, shore hardness, and any other data necessary to identify the parts fully.

S2.1.2 In cases in which standard commercial or military parts are or can be used, these shall be appropriately identified.

S2.1.3 Outline dimensions, disassembly space, location, and size of end connections and mounts.

S2.1.4 Estimated weight and center of gravity (vertical, longitudinal, and transverse).

S2.1.5 Recommended assembly torques or equivalent procedures for making up all joints and threaded assemblies.

S2.1.6 The following information shall be included: (1) pressure rating, (2) contaminant removal rating, (3) clean pressure drop at filter-rated flow capacity, (4) differential pressure indicator setting (Style I filters), and (5) automatic bypass valve setting (Composition A filters).

S2.2 Technical Manuals—Technical manuals shall provide a description, installation procedures, operation and maintenance instructions, and illustrated parts breakdown for the filter, organized as follows:

S2.2.1 Chapter 1—General information and safety precautions.

S2.2.2 Chapter 2—Operation.

S2.2.3 Chapter 3—Functional description.

S2.2.4 Chapter 4—Scheduled maintenance.

S2.2.5 Chapter 5—Troubleshooting.

S2.2.6 Chapter 6—Corrective maintenance.

S2.2.7 Chapter 7—Parts list.

S2.2.8 Chapter 8—Installation.

S2.3 In addition, the following shall be included as part of the technical manual contents:

S2.3.1 The assembly drawings for the filter, supplemented by additional illustrations where necessary to illustrate operation and maintenance adequately. These additional illustrations may consist of blowouts or partial or full sections and may eliminate extraneous lines and details to clarify the interaction of parts.

S2.3.2 Table listing wrench sizes and assembly torques (or other equivalent procedures) for making up all joints and threaded assemblies.

S2.3.3 Detailed disassembly and reassembly procedures. In addition to a section providing procedures for the complete disassembly and reassembly of the filter, maintenance and troubleshooting sections shall contain, or refer to, only the limited disassembly and reassembly required to accomplish each particular operation. This is intended to reduce the possibility of unnecessary disassembly and unnecessary disturbance of adjustments when performing specific or limited maintenance or troubleshooting operations.

S2.3.4 Adjustment procedures for the differential pressure indicator and the automatic bypass valve (where applicable).

S3. Quality Assurance

S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish and, from time to time, to alter whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organized freedom to identify quality control problems and to initiate, recommend, and provide solutions.

S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.

S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacturer. The manufacturer shall maintain control of material during the manufacturing process by a system that identifies status of material throughout all stages of manufacture.

S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.

S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made to the inspection authority if required.

S3.11 Nondestructive Examination—Provisions shall be made to use nondestructive examination, as necessary, to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer or qualified by a recognized national body or both, and their authorizations/qualification records shall be made available to the inspection authority if required.
X1. GUIDELINES FOR THE SELECTION AND INSTALLATION OF FILTERS

X1.1 Scope—This appendix provides general guidelines for the selection and installation of filters in air or nitrogen systems, and therefore, its use does not in any way relieve the user of his final responsibility in the selection and installation of filters.

X1.2 Contamination Removal Rating (also commonly termed: “filter rating” or “micrometre rating”)—The finer the contamination removal rating specified, the more frequently it will be necessary to clean (or replace) the filter element. Therefore, only the actual desired level of filtration required by a particular application, and as shown by design analysis or operating experience, should be specified.

X1.3 Filter Element Bypass—A filter element bypass should be specified for any application where a partial or full blockage of fluid flow is not acceptable. Some or all of the fluid flow under such circumstances will be unfiltered. Where a constant supply of filtered fluid is necessary, a multiple-filter approach should be considered. An adjustable filter element bypass allows setting (within the limits of adjustment provided) the pressure drop at which bypass of flow initiates.

X1.4 Permanent Versus Disposal Elements—Permanent filter elements are designed to provide specified performance repeatedly up to a specified number of cleaning from a contaminated condition. Disposable filter elements require replacement with a new like element each time they reach a contaminated condition. Permanent elements can reduce inventory requirements. Disposable elements can reduce initial costs and maintenance requirements.

X1.5 Contaminant-Holding Capacity—To a certain extent, contaminant-holding capacity is proportional to the flow...
capacity-pressure drop capabilities of a filter element. Different filter mediums, however, hold contaminants in different ways, giving different contaminant-holding capacities for any given initial (clean) flow capacity-pressure drop capability, and therefore, it is necessary to specify contaminant-holding capacity as a separate parameter.

X1.6 Differential Pressure Indicator—A filter element differential pressure indicator warns of a high contamination level before it reaches the point at which the flow of filtered fluid is no longer adequate to meet system requirements or a bypass will begin to open. An adjustable filter element differential pressure indicator allows setting (within the limits of adjustment provided) the pressure drop at which the indicator actuates.
Standard Specification for Special Requirements for Valves Used in Gaseous Oxygen Service

This standard is issued under the fixed designation F 1792; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the special requirements for valves used in gaseous oxygen service. It is intended that this specification be invoked as an additional requirement in conjunction with primary valve specifications.

1.2 The values stated in this specification in inch-pound units are to be regarded as the standard. The SI equivalent shown in parenthesis are provided for information only.

2.4 Military Standards and Specifications:
   MIL-V-5027 Valves, Check, Oxygen, High Pressure
   MIL-STD-278 Fabrication, Welding and Inspection; Cast-

3. Ordering Information

3.1 Ordering documentation for valves under this specification shall include the following information, as required, to describe the equipment adequately:

3.1.1 ASTM designation and year of issue.
3.1.2 Primary valve specification (see 1.1).
3.1.3 End preparations, if different than specified in 4.4.
3.1.4 Supplementary requirements, if any (see SI through S4).

4. Valve Design and Construction

4.1 Valves shall incorporate the features specified in 4.2-4.6.

4.2 Materials of Construction—Material requirements shall be as follows:

4.2.1 The pressure containing/retaining envelope (including any bolting, union nuts, or other fastening devices establishing the integrity of the pressure containing/retaining envelope), bellows (where applicable), and end nipples, shall be nickel-copper (70-30). Internal trim which is in contact with the line media shall be nickel-copper (70-30), bronze, nickel-aluminum-bronze, Inconel Alloy 600, brass, or other materials which are compatible with oxygen service.

4.2.2 Non-metallic seat, seat insert, or seals. These materials shall be from TFE, Reinforced TFE, CTFE, plastic in accordance with MIL-P-46122, Polyamide (Vespel), or PEEK. The materials for O-rings and gaskets shall be compatible for oxygen service.

4.2.3 Lubricants—Materials for lubricants shall be halocarbon (25-5S), Dupont (Krytox 240 AC, 240 AZ), Braycote 601, or other lubricants compatible with oxygen service.

4.2.4 Guidance on the selection of materials for oxygen service can be found in Guides G 63 and G 94. Guidance on designing systems for oxygen service can be found in Guide G 88.
4.3 General Requirements:

4.3.1 Fire Prevention—Valves shall be constructed to minimize the possibility of initiating ignition in gaseous oxygen service. This shall be accomplished by the following:

4.3.1.1 Materials for parts in contact with oxygen shall have the highest spontaneous ignition temperatures and the lowest impact sensitivities compatible with construction and performance limitations.

4.3.1.2 Surfaces in contact with oxygen shall be smooth with well-rounded edges and without sharp or thin sectioned protrusions (that is, all parts shall have a high ratio of volume-to-surface area). Sharp exterior corners are prohibited, and interior corners shall have fillets to prevent the retention or entrapment of machining chips, burrs, or foreign material.

4.3.1.3 Nonmetallic materials (O-rings, gaskets, etc.) other than the seating insert, if applicable, shall be well removed from the main flow path.

4.3.2 Fire Containment—Valves shall be constructed to minimize oxygen escape in the event of an internal or external fire. This shall be accomplished by the following:

4.3.2.1 Pressure-Boundary Sealing—Joints for the pressure-boundary seals shall provide an effective barrier to leakage in the event of damage or consumption of the non-metallic sealing elements by providing long, close fitting metal-to-metal leakage or flame paths.

4.3.2.2 Internal Seating—The seat design shall be such that in the event that the non-metallic seat is damaged, destroyed, or carried away, there will be a secondary metal-to-metal seat to minimize through seat leakage. The construction and location of the nonmetallic seals and seating inserts shall minimize the possibility of ignition under a pressure surge.

4.3.2.3 Pressure Surge—Valves shall be designed to prevent pressure surge, which could cause auto-ignition.

4.4 Design Features:

4.4.1 Manual valves shall be of the packless design, with the stem sealed by a bellows.

4.4.2 Threads—Threads shall conform to ANSI B1.1. Use of threads in contact with oxygen shall be minimized. Any threads wetted by oxygen shall be of rolled construction or shall be completely chamfered and deburred to prevent the possibility of sharp edges or machining burrs in contact with oxygen.

4.4.3 Cleaning—Prior to assembly and testing, valves shall be degreased and cleaned in accordance with Practice G 93, and thereafter maintained clean for oxygen service.

4.5 End Preparation—Unless otherwise specified (see Section 3), end preparation for the valves shall be as follows:

4.5.1 Valves shall be supplied with inline extension nipples welded directly to the valve body or fabricated as an integral part of the valve body. Nipples shall be of the same basic material as the body. The length and schedule of these nipples shall be as specified in Table 1.

4.6 Welding and Nondestructive Testing—Welding and nondestructive testing shall be in accordance with ASME Boiler and Pressure Vessel Code, Sections VIII and IX.

5. Marking

5.1 Identification Plates—A metallic corrosion-resisting identification plate shall be securely attached to the valve and shall indicate “Valve specially made for oxygen service”.

5.2 In addition, each valve shall be marked in accordance with their applicable primary valve specification requirements.

6. Quality Assurance System

6.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied.

6.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

6.3 The purchaser reserves the right to witness any tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1, S2, S3, or S4 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

**S1. Supplemental Tests**

S1.1 Supplemental tests shall be conducted at a laboratory satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.2 through S1.4.

S1.2 Examination Prior to Testing—The valve(s) shall be examined visually to determine conformance with the ordering data, dimensions, and workmanship without disassembly.

S1.3 Nonmetallic Materials Compatibility Test—Materials shall be subjected to the ozone-resistance and oxygen-bomb tests as specified in MIL-V-5027, with test pressure applicable to the valve under test. No charring or deterioration is allowed.

S1.4 Nondestructive Testing—Nondestructive testing shall be in accordance with MIL-STD-271.
S2. Cleaning, Drying, Packaging, and Marking Requirements

S2.1 Valves shall be cleaned, dried, packaged, and marked in accordance with MIL-STD-1330. Packaging operations shall be accomplished in an area that will prevent valve contamination by hydrocarbons.

S3. Quality Assurance

S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.

S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.

S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system that identified inspection status of material throughout all stages of manufacture.

S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions utilizing documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.

S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.

S3.11 Nondestructive Examination—Provisions shall be made to utilize non-destructive examination, as necessary, to ensure that material and components comply with the specified requirements. Non-destructive examinations shall be authorized by their employer and/or qualified by a recognized national body, and their authorizations/qualification records shall be made available to the inspection authority if required.

S3.12 Non-Conforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.

S3.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.

S3.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during all stages of manufacture and shall be able to distinguish between inspected and non-inspected material.

S3.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S3.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, photographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S3.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S3.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

S4. Special Fabrication Requirements

S4.1 Welding Requirements—Welding shall be in accordance with MIL-STD-278.
Designation: F 1793 – 97 (Reapproved 2004)

An American National Standard

Standard Specification for Automatic Shut-Off Valves (Also Known as Excess Flow Valves, EFV) for Air Or Nitrogen Service

This standard is issued under the fixed designation F 1793; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers self-contained automatic shut-off valves (also known as excess flow valves) for air or nitrogen service. They are intended to be installed as safety devices to quickly and automatically shut off flow under certain excess flow conditions caused by a downstream failure or casualty, such as a hose rupture.

1.2 The values stated in this specification in inch-pound units are to be regarded as the standard. The SI equivalents shown in parentheses are provided for information only.

NAVSEA 803-1385946 Unions, Bronze Silver Brazing, WOG for UT Inspection

3. Terminology

3.1 Definitions:
3.1.1 automatic shut-off valve—automatic shut-off valves covered by this specification trip shut in response to the pressure differential across the valve.
3.1.2 bubble-tight—no visible leakage over a 3-min period using either water submersion or the application of bubble fluid for detection.
3.1.3 external leakage—leakage from the automatic shut-off valve that escapes to atmosphere.
3.1.4 hydrostatic shell test pressure—the hydrostatic shell test pressure that the automatic shut-off valve is required to withstand without damage. Automatic shut-off valve operation is not required during application of shell test pressure, but it must meet all performance requirements after the shell test pressure has been removed.
3.1.5 pressure ratings—the pressure ratings of the automatic shut-off valves shall be as defined in the documents listed in Table 1. The pressure ratings (also called pressure-temperature ratings) establish the maximum allowable working (service) pressures of a component (valve, end connections, and so forth) at various temperatures.
3.1.6 seat tightness—the ability of the automatic shut-off valve to prevent leakage from the valve-inlet to the valve-outlet.
3.1.7 set point—a combination of inlet pressure and flow, at which the valve trips shut.
3.1.8 set point accuracy—the band of accuracy of the automatic shut-off valve expressed as a range of flow rates at a given inlet pressure, established by the following two points:

A For Union inlet and outlet end connections, only the pertinent dimensions listed in the applicable documents (Military Specification or NAVSEA Requirements) shall apply. The valve shall be supplied with the thread-pieces only, without the tail-pieces and union-nuts.

3.1.8.1 Discussion—A combination of inlet pressure-flow, at or below which the automatic shut-off valve will not trip shut (valve will remain open) regardless of influences such as spring relaxation, mechanical shock or vibration, and so forth.

3.1.8.2 A combination of inlet pressure-flow, at or above which the automatic shut-off valve will trip shut (valve will not remain open) regardless of influences tending to resist closure such as breakloose friction, corrosion, or sludge, and so forth.

3.1.9 Set-point range—the range of set points over which the automatic shut-off valve can be adjusted. Expressed as a range of flow rates at a given inlet pressure.

4. Classification

4.1 Automatic shut-off valves shall be of the following types, styles, sizes, pressure ratings, and end connections:

4.1.1 Types:

4.1.1.1 Type I—Valves that can be adjusted or repaired without removing the valve from pipe line.

4.1.1.2 Type II—Valves that cannot be adjusted or repaired without removing the valve from pipe line.

4.1.2 Styles:

4.1.2.1 Style 1—Automatic Reset Construction—These valves are designed to limit the flow of air or nitrogen upon closure to a small predetermined level. These valves reset automatically once the service line downstream is made air or nitrogen-tight and pressure is equalized across the valve.

4.1.2.2 Style 2—Manual Reset Construction—These valves are designed to stop the flow of air or nitrogen upon closure. These valves must be manually reset.

4.1.3 Sizes—Automatic shut-off valves shall be of the following NPS sizes: ¼ (13.5 mm), ⅜ (17.2 mm), ½ (21.3 mm), ⅝ (26.9 mm), 1 (33.7 mm), 1¼ (42.4 mm), 1½ (48.3 mm), and 2 (60.3 mm). Unless otherwise specified in 5.0, the valve inlet size shall be the same as the outlet size.

4.1.4 Pressure Ratings—Automatic shut-off valves shall have pressure rating(s) selected (see 3.1.5) from Table 1. The pressure rating(s) selected shall be specified in Section 5.

inlet and outlet pressure ratings of the automatic shut-off valve shall be the same for any given valve.

4.1.5 End Connections—Automatic shut-off valves shall have end connections selected from those listed in Table 1 and specified in Section 5.

5. Ordering Information

5.1 Ordering documentation for automatic shut-off valves under this specification shall include the following information, as required, to describe the equipment adequately:

5.1.1 ASTM designation and year of issue,

5.1.2 Valve type (see 4.1.1),

5.1.3 Valve style (see 4.1.2),

5.1.4 Valve size (see 4.1.3),

5.1.5 Valve pressure rating (see 4.1.4),

5.1.6 End connections (see 4.1.5),

5.1.7 Valve inlet operating pressure,

5.1.8 Set point (see 3.1.7 and 7.2),

5.1.9 Tamper-proof set point adjustment, if required (see 6.3.2),

5.1.10 Supplementary requirements, if any (see S1 through S4), and

5.1.11 Maximum vibration frequency and displacement amplitude, if other than specified (see S1.2).

6. Valve Construction

6.1 Valves shall incorporate the features specified in 6.2-6.16.

6.2 Materials of Construction—Material requirements for the automatic shut-off valve shall be as follows: The pressure-containing envelope shall be 300 series corrosion-resistant steel (304, 304L, 316, or 316L). Internal parts including springs, poppets, retainers, etc. shall be 300 series corrosion-resistant steel, nickel-aluminum-bronze, nickel-copper (70-30), or bronze. Other materials for both the pressure-containing envelope and internal parts may be selected to assure compatibility with the line medium, weldability, and to provide corrosion resistance without requiring painting, coating, or plating. Materials for contacting parts shall be selected to minimize electrolytic corrosion and galling.

6.3 General Requirements:

6.3.1 Automatic shut-off valves shall be self-contained, requiring no external power source for operation. The automatic shut-off valve shall be capable of meeting all requirements of this specification and provide extended reliable operation.

6.3.2 Automatic shut-off valves shall incorporate a provision for manually resetting. This shall constitute an isolatable bleed-by which is operable with the valve in the pipeline under pressure and which functions by equalizing pressure across the poppet. Style 1 valves shall in addition, incorporate a provision which automatically resets the valve, and which constitutes a small non-isolatable bleed-by.

6.4 Threads—Threads shall be as specified in ANSI B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used. Any exposed threads shall be protected by plastic caps for shipping.
6.5 Interchangeability—The automatic shut-off valve, including all associated piece parts, shall have part number identity, and shall be replaceable from stock or the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s part number shall be directly interchangeable with each other with regard to installation (physical) and performance (functional). Physically interchangeable assemblies, components, and parts are those which are capable of being readily installed, removed or replaced without alteration, misalignment, or damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.6 Nonmetallic Element Interchangeability—Nonmetallic elements, including but not limited to, seat rings, poppet seat inserts, cushions, and O-rings shall be treated as separately identified and readily replaceable parts.

6.7 Maintainability—Maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified, and shall be supplied as part of the valve.

6.8 Reversibility—Seating inserts, if applicable, shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.9 Adjustments—There shall be no adjustments required in the automatic shut-off valve during or after assembly other than the set point.

6.10 Pressure Envelope—The valve shall be designed to pass a hydrostatic shell test at a pressure of at least 1.5 times the 100°F (38°C) pressure rating of the valve without damage.

6.11 Body Construction—All pressure lines, including the reset bleed line, shall be internally ported. The bonnet and bottom cap (where applicable) shall be attached to the body by bolting, threading, or threaded-union connections.

6.12 Set-Point Adjustment—Set point shall be adjustable through the range specified in 7.4. Type I valves shall be adjustable with the valve in the line under pressure. Type II valves may be removed from the line for adjustment. The set point shall incorporate right-hand threads so that a clockwise rotation increases the set point. Means shall be used to prevent an accidental or inadvertent change in set point. The option of a tamper-proof set-point adjustment (lead seal, and so forth) shall be available and shall be specified as in Section 5.

6.13 Port Configuration—The automatic shut-off valve shall have in-line inlet and outlet ports.

6.14 Springs—Spring incorporated in the automatic shut-off valve shall not be compressed solid during operation. Spring ends shall be squared and ground. Engagement or disengagement of parts against spring compression shall not be permitted.

6.15 Guiding—The valve poppet shall be guided to prevent binding or seizing, and to ensure proper seating under all operating conditions. Proper alignment of all internal operating parts shall be maintained with interchangeable parts and under all tolerance stack-up conditions.

6.16 Accessibility—Type I automatic shut-off valve shall be accessible for adjustment or service, without removing the automatic shut-off valve from the line.

7. Performance Requirements

7.1 Automatic shut-off valves shall meet the requirements of 7.2-7.8.

7.2 Set Point—The required set point as defined in 3.1.7, shall be as specified (see Section 5).

7.3 Set-Point Accuracy—The set-point accuracy, as defined in 3.1.8, shall be plus or minus 10 % of the set point.

7.4 Range of Set-Point Adjustment—Automatic shut-off valves shall be capable of meeting all performance requirements when set at any point within plus or minus 25 % of the nominal specified set point.

7.5 Trip Differential Pressure—The pressure differential at which the automatic shut-off valve trips shut shall not exceed the values specified in Table 2.

7.6 Reset Pressure—Once shut, the automatic shut-off valve shall remain shut until the pressure across the valve is equalized.

7.7 Seat Tightness—Once shut, and with the manually operated isolatable bleed-by closed, the automatic shut-off valve shall meet the following seat tightness requirements. Where necessary, leakage measurement shall start after temperature stabilization.

7.7.1 Style I Valves—Flow leakage shall be less than 2 % and no greater than 5 % of the set-point flow.

7.7.2 Style 2 Valves—Flow leakage shall not exceed 60 standard cubic inches per hour (SCIH), per inch of valve size.

7.8 External Leakage—The automatic shut-off valve external leakage shall be bubble-tight at its operating pressure conditions over a 3-min period.

8. Tests Required

8.1 Each automatic shut-off valve must pass the tests outlined in 8.2-8.6.

8.2 Visual Examination—The automatic shut-off valve shall be examined visually to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

8.3 Hydrostatic Shell Test—The automatic shut-off valve shall be hydrostatically tested using water by applying a test pressure equal to the 1.5 times the 100°F (38°C) pressure rating to the valve inlet and outlet to check its structural integrity. Pressure shall be applied for three minutes. Air or nitrogen may be used in lieu of water, providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible fluid. There shall be no external leakage, permanent distortion, or structural failure.

8.4 Seal Tightness Test (Style 2 Valves Only)—The automatic shut-off valve shall be tested with air or nitrogen gas with an inlet test pressure equal to the 1.1 times the 100°F (38°C) pressure rating. The leakage requirements of 7.7 shall be met.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1, S2, S3, or S4 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. Supplemental Tests

S1.1 Supplemental tests shall be conducted at a laboratory satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.2 through S1.5.

S1.2 Shock Test—The automatic shut-off valve shall be subjected to and meet the high-impact shock tests for grade A, class I as specified in MIL-S-901 pressurized with water, air, or nitrogen. The inlet port shall be pressurized to the maximum operating pressure. There shall be no structural damage to the automatic shut-off valve. There shall be no degradation to the performance capability of the automatic shut-off valve. Tripping shut of the automatic shut-off valve is permissible.

S1.3 Vibration Test—The automatic shut-off valve shall be vibration tested in accordance with type I of MIL-STD-167-1 pressurized with water, air, or nitrogen. The inlet port shall be pressurized to the maximum inlet operating pressure. At frequencies up to and including 33 Hz (unless otherwise specified in the ordering information, Section 5), there shall be no resonance in the range of frequencies tested. There shall be no structural damage or degradation to the performance capability of the automatic shut-off valve.

S1.4 Noise Test—The automatic shut-off valve shall be tested for airborne noise in accordance with MIL-STD-740-1. The noise (sound pressure level) shall not exceed 85 db observed at one-metre distance from the automatic shut-off valve.

S1.5 Posttest Examination—The automatic shut-off valve shall be disassembled and examined for any evidence of excessive wear, degradation, or impending damage or breakage.

S2. Technical Data and Certification Requirements

S2.1 Drawings—Assembly drawings or catalog sheets of the automatic shut-off valve which clearly depict design shall be provided. The following information shall also be included as part of the drawings or catalog sheets:

S2.1.1 Bill of material listing specification, grade, condition, and any other data required to fully identify the properties of the materials proposed. This shall include identifications, material and size designations, shore hardness, and any other data necessary to fully identify the parts.

S2.1.2 In cases where standard commercial or military parts are or can be employed, these shall be appropriately identified.
S2.1.3 Outline dimensions, disassembly space, location, and size of end connections.
S2.1.4 Estimated weight and center of gravity (vertical, longitudinal, and transverse).
S2.1.5 Recommended assembly torques or equivalent procedures for making up all joints and threaded assemblies.
S2.1.6 The following performance information shall be included:
S2.1.6.1 Set point and adjustable range.
S2.1.6.2 Specified operating conditions.
S2.2 Technical Manuals—Technical manuals shall provide a description, installation procedures, operation and maintenance instructions, and illustrated parts breakdown for the automatic shut-off valve, organized as follows:
S2.2.1 Chapter 1—General Information and Safety Precautions.
S2.2.2 Chapter 2—Operation.
S2.2.3 Chapter 3—Functional Description.
S2.2.4 Chapter 4—Scheduled Maintenance.
S2.2.5 Chapter 5—Troubleshooting.
S2.2.6 Chapter 6—Corrective Maintenance.
S2.2.7 Chapter 7—Parts List.
S2.2.8 Chapter 8—Installation.
S2.2.9 In addition, the following shall be included as part of the technical manual content:
S2.2.9.1 The assembly drawings for the automatic shut-off valve, supplemented by additional illustrations where necessary to adequately illustrate operation and maintenance. These additional illustrations may consist of blowouts, partial or full sections, and may eliminate extraneous lines and details to clarify the interaction of parts.
S2.2.9.2 Table listing wrench sizes and assembly torques (or other equivalent procedures) for making up all joints and threaded assemblies.
S2.2.9.3 Detailed disassembly and reassembly procedures. In addition to a section providing procedures for the complete disassembly and reassembly of the automatic shut-off valve, maintenance and troubleshooting sections shall contain, or refer to, only the limited disassembly and reassembly required to accomplish each particular operation. This is intended to reduce the possibility of unnecessary disassembly and unnecessary disturbance of adjustments when performing specific or limited maintenance or troubleshooting operations.
S2.2.9.4 Adjustment procedures for the automatic shut-off valve.

S3. Quality Assurance

S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.
S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.
S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.
S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.
S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.
S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.
S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system that identified inspection status of material throughout all stages of manufacture.
S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions utilizing documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.
S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.
S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.
S3.11 Nondestructive Examination—Provisions shall be made to utilize non-destructive examination, as necessary, to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer and/or qualified by a recognized national body, and their authorizations/qualification records shall be made available to the inspection authority if required.
S3.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.
S3.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.
X1. GUIDELINES FOR SELECTION OF AUTOMATIC SHUT-OFF VALVES

X1.1 Scope—This appendix provides general guidelines for the selection of automatic shut-off valves, and therefore, its use does not in any way relieve the user of the final responsibility in the selection and installation of automatic shut-off valves.

X1.2 The automatic shut-off valves described by this specification are intended to be installed as safety devices in air or nitrogen service to quickly and automatically shut off flow under certain excess flow conditions caused by a downstream failure, such as a hose rupture. They are designed to respond only to the pressure differential across the automatic shut-off valve created by the flow. Therefore, these valves are not intended primarily to preserve the upstream fluid from causes such as a slow downstream leak.

X1.2.1 In the open position and under no flow conditions, the valve is fully balanced with no net pressure force tending to open or close the valve. The valve is actuated to close when the pressure drop across the valve caused by a flow exceeds a set valve. The valve is set by adjusting the distance between the poppet and the seat in the open position (that is, changing the restriction to flow presented by the valve) and thereby changing the flow-pressure conditions under which the set pressure drop occurs. Once shut, the valve remains shut until the static pressure drop across the valve is reduced.

X1.3 To function as intended, the characteristics of the system and the location of the automatic shut-off valve must be such that the lowest pressure drop created across the automatic shut-off valve as the result of a casualty will always be greater than the highest pressure drop created across the valve during any normal operating condition. The separation between these two points must be sufficient to be compatible with the accuracy of the automatic shut-off valve selected. If there is not a sufficient separation, or if these points overlap, then either the automatic shut-off valve will inadvertently trip shut during certain normal operating situations, or it will fail to trip shut under certain casualty situations, or both, and therefore, its successful application will not be possible.

X1.4 Since the automatic shut-off valve is statically pressure balanced, the set point at which it would trip shut is established by the spring preload tending to hold the poppet in the open position combined with the flow restriction presented by the valve when in the open position.

X1.5 Type I automatic shut-off valves are intended to provide maximum maintainability (particularly in systems where removal and reinstallation of the valve body from the pipe-line may be difficult because of pipe spring) by permitting valve adjustment and removal of all valve internals with the valve in the pipe-line. Type II automatic shut-off valves require removal of the valve from the pipe-line for adjustment or repair and are intended for applications where compactness and light-weight are the primary considerations.
ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Specification for
Hand-Operated, Globe-Style Valves for Gas (Except Oxygen Gas) and Hydraulic Systems

1. Scope

1.1 This specification covers the design, construction, testing, and operating requirements for hand-operated, quick-change cartridge trim, in-line body and angle-body, globe-style valves for use in gas (except oxygen gas) and hydraulic systems. These valves may be used for on-off, and/or throttling applications.

1.2 The values stated in this specification in inch-pound units are to be regarded as the standard. The SI equivalents shown in parenthesis are provided for information only.

3. Terminology

3.1 Definitions:
3.1.1 bubble-tight—no visible leakage over a 3-min period using either water submersion or the application of bubble fluid for detection.
3.1.2 external leakage—leakage from the valve that escapes to atmosphere.
3.1.3 flow capacity—the ability of a valve to pass flow under any given set of pressure conditions. The flow capacity of a valve is directly related to its Flow Coefficient (Cv). The Flow coefficient is the quantity of water passing through a valve, expressed in gallons/minute (litres/minute), when 1 psi (6.895 kPa) pressure drop at 60°F (16°C) is applied across the valve.
3.1.4 globe-style valves—a basic control valve type that gets its name from the globular shape of its body with an internal bridgewidth construction. It normally uses a basic rising stem/plug for the closure member.
3.1.5 hydrostatic shell test pressures—the hydrostatic test pressures that the valve is required to withstand without damage. Valve operation is not required during application of shell test pressure, but the valve must meet all performance requirements after the shell test pressure has been removed.
3.1.6 internal leakage—leakage from higher pressure to lower pressure portions of the valve.
3.1.7 operating pressures—the pressures within the valve during service.
3.1.8 pressure ratings—the pressure ratings of the valve shall be as defined in the documents listed in Table 1. The pressure ratings (also called pressure-temperature ratings)

---

1 This specification is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.11 on Machinery and Piping Systems.

4 Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.
establish the maximum allowable working (service) pressures of a component (valve, end connections, and so forth) at various temperatures.

3.1.9 quick-change cartridge trim—a construction that facilitates rapid and reliable seat-ring/seat removal and replacement by retaining the seat-ring/seat in the valve cartridge, as opposed to a seat-ring which is threaded, welded, brazed, or made integral with the valve body.

3.1.10 seat tightness—the ability of a valve to prevent internal leakage from the valve-inlet to the valve-outlet.

4. Classification

4.1 Valves shall be of the following types, styles, sizes, pressure ratings, and end connections, as specified in Section 5.

4.1.1 Types—Valves shall have either Type I (angle body construction) or Type II (inline body construction).

4.1.2 Styles—Valves shall be either Style I (shut-off valves) or Style 2 (throttling valves).

4.1.3 Sizes—Valve sizes shall be 1/8 NPS (10.2 mm), 1/4 NPS (13.5 mm), 5/8 NPS (17.2 mm), 1/2 NPS (21.3 mm), 3/4 NPS (26.9 mm), 1 NPS (33.7 mm), 1 1/4 NPS (42.4 mm), 1 1/2 NPS (48.3 mm), and 2 NPS (60.3 mm).

4.1.4 Pressure Ratings—Valves shall have a pressure rating selected from those listed in Table 1 and specified in Section 5. The inlet and outlet pressure ratings of the valve shall be identical for any given valve.

4.1.5 End Connections—Valves shall have end connections selected from those listed in Table 1 and specified in Section 5. The inlet and outlet end connections of the valve shall be identical for any given valve.

5. Ordering Information

5.1 Ordering documentation for valves under this specification shall include the following information, as required to describe the equipment adequately.

5.1.1 ASTM designation and year of issue.

5.1.2 Valve type (see 4.1.1).

5.1.3 Valve style (see 4.1.2).

5.1.4 Valve size (see 4.1.3).

5.1.5 Valve pressure rating (see 4.1.4).

5.1.6 Valve end connections (see 4.1.5).

5.1.7 Line medium.

5.1.8 Temperature of line medium.

5.1.9 Supplementary requirements, if any (see S1 through S4).

5.1.10 Maximum vibration frequency and displacement amplitude, if other than specified (see S1.4), and

5.1.11 Maximum permissible noise level, if other than specified (see S1.5).

6. Valve Construction

6.1 Valves shall incorporate the design features specified in 6.1.1-6.1.17.

6.1.1 General Requirements:

6.1.1.1 Valves furnished under this specification shall be soft-seated, globe-style valves using a cartridge in which all working parts including the seat are removable as an assembly.

6.1.2 Materials of Construction—Material requirements for these valves shall be as follows: The pressure containing envelope shall be 300 series corrosion-resistant steel, nickel-copper (70-30), nickel-aluminum-bronze, or bronze. Internal parts in contact with the line media shall be 300 series corrosion-resistant steel, nickel-copper (70-30), copper-nickel (70-30), bronze, nickel-aluminum-bronze, or naval brass. Other materials not listed above may be selected to assure compatibility with the line medium, weldability, and to provide corrosion resistance without requiring painting, coating, or plating. Materials for contacting parts shall be selected to minimize electrolytic corrosion and galling.

6.1.3 Soft-Seating Insert—A soft-seating (non-metallic) insert, if applicable, shall be field replaceable and incorporated in the valve plug. Soft-seating inserts shall be protected from direct flow impingement, excessive loading and extrusion, or any other effect jeopardizing their useful life. Soft-seating inserts shall be of the simplest practical configuration to facilitate emergency replacement manufacture where necessary.

6.1.4 Pressure Envelope—The valve shall be designed to pass a hydrostatic shell test at a pressure of at least 1.5 times the 100°F (38°C) pressure rating of the valve without any damage.

6.1.5 Threads—Threads shall be as specified in ANSI B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used. Any exposed threads shall be protected by plastic caps for shipping.

6.1.6 Accessibility—All internal parts of the valve shall be accessible for adjustment or service, without removing the valve body from the line.

6.1.7 Interchangeability—The valve, including all associated piece parts, shall have part number identity, and shall be replaceable from stock or the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s part number shall be directly interchangeable with each other with respect to installation (physical) and performance (function).
Physically interchangeable assemblies, components, and parts are those which are capable of being readily installed, removed, or replaced without alteration, misalignment, or damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.1.8 Nonmetallic Element Interchangeability—Nonmetallic elements, including but not limited to, seat rings, soft-seating inserts, cushions, and O-rings shall be treated as separately identified and readily replaceable parts.

6.1.9 Maintainability—Valve maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified, and shall be supplied with the valve.

6.1.10 Reversibility—Seat inserts shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.1.11 Adjustments—There shall be no adjustments required in the valve during or after assembly.

6.1.12 Bidirectional Operation and Bubbletight Shut-Off—The valve shall be capable of operation and bubbletight shut-off with a differential pressure equal to the rated pressure applied across the valve in either direction of flow.

6.1.13 Guiding—The valve poppet shall be guided to prevent binding or seizing, and to ensure proper seating, under all operating conditions. Proper alignment of all internal operating parts shall be maintained with interchangeable parts and under all tolerance stack-up conditions.

6.1.14 Valve Operating Force—The maximum permissible total tangential force required on the handwheel/handle for operating or seating/unseating the valve shall not exceed 50 lb (222 N), when the valve is subjected to a differential pressure equal to the rated pressure applied across the valve in either direction of flow.

6.1.15 Pressurization Rate—To prevent the possibility of auto-ignition, the valve shall be capable of being operated to limit the rate of downstream pressure buildup in a depressurized volume (with the rated pressure upstream) to 200 psi (1380 kPa) per second. Downstream volumes for this pressurization rate shall be taken as 10 pipe diameters.

6.1.16 Operation—The valve shall close by a clockwise rotation of handwheel/handle when viewed from directly over the handwheel/handle.

6.1.17 Envelope Dimensions—For union-end valves only, the overall envelope dimensions shall be as shown in Fig. 1 (angle body construction) or Fig. 2 (inline body construction), as applicable, and Table 2.

7. Performance

7.1 Valves shall meet the performance requirements of 7.1.1-7.1.3.

7.1.1 Flow Capacity—The flow capacity of the valve, expressed in terms of $C_v$, shall be equal or greater than the values shown in Table 3.

7.1.2 Seat Tightness—Valve shall be bubbletight at 1.1 times the 100°F (38°C) pressure rating in both directions when closed with a handwheel/handle force not exceeding that specified in 6.1.14 (or the manufacturer’s published recommendations, when less).

7.1.3 External Leakage—Valve external leakage shall be bubbletight at its 100°F (38°C) pressure rating.

8. Tests Required

8.1 Each valve shall pass the tests outlined in 8.1.1-8.1.4.

8.1.1 Visual Examination—The valve shall be examined visually to determine conformance with the ordering data and workmanship without disassembly.

8.1.2 Hydrostatic Shell Test—The valve shall be hydrostatically tested with water by applying test pressures equal to 1.5 times the 100°F (38°C) pressure rating to the inlet and outlet ports (with the valve in the open position) to check the
structural integrity of the valve. Pressure shall be applied for three minutes. Air or nitrogen may be used in lieu of water, providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible fluid. There shall be no external leakage, permanent distortion, or structural failure.

8.1.3 Seat Tightness Test—The valve shall be seated with an applied handwheel/handle force not exceeding that specified in 6.1.14 (or the manufacturer’s published recommendations, when less). Air or nitrogen at 1.1 times the 100°F (38°C) pressure rating of the valve shall be used for seat tightness test, using bubble fluid or immersing the outlet, or a line from the outlet, under water. The valve shall show no visible evidence of leakage over a 3-min period. The valve shall be tested in both directions of flow to assure bidirectional seat tightness. For valves used for helium or helium mixture service, the testing medium shall be helium or helium/nitrogen mixture.

8.1.4 External Leakage Test—With the valve in the partially open position, air or nitrogen shall be applied at a test pressure equal to the 100°F (38°C) pressure rating of the valve to the inlet port, and the outlet port blanked off. External leakage shall be checked using bubble fluid, or by submerging the valve in water. There shall be no visible external leakage over a 3-min period. For valves used for helium or helium mixture service, the testing medium shall be helium or helium/nitrogen mixture.

9. Marking

9.1 Identification Plate—An identification plate of corrosion-resistant metal in accordance with Specification F 992; Types I, II, III, or IV shall be permanently attached to the valve and shall include the following information (some or all information may instead be stamped, etched, or cast on the valve body):

9.1.1 Manufacturer’s name,
9.1.2 ASTM designation and year of issue,
9.1.3 Manufacturer’s model/part number,
9.1.4 Size, and
9.1.5 Pressure rating.

9.2 Body Markings—Valve body shall be marked per ANSI B16.34.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied. This system shall also ensure that all valves will perform in a similar manner to those representative valves subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the valves in the manufacturer’s plant to the extent specified on the purchase order.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1, S2, S3, or S4 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.
S1. Supplemental Tests

S1.1 Supplemental tests shall be conducted at a laboratory satisfactory to the customer and shall consist of the examination and tests selected from those specified in S1.1.1 through S1.1.6.

S1.1.1 Operational Test—The valve shall be attached to an air or nitrogen source at the rated pressure with flow through the valve over the seat. A needle valve shall be installed downstream to limit flow during cycling tests. The valve shall be cycled as follows:

(a) Cycle 50 times and then seat valve with the maximum seating force as specified per manufacturer’s recommended published data. One cycle shall consist of one complete opening and closing.

(b) Allow valve to remain pressurized for 1 h in the seated condition.

(c) Repeat (a) and (b) above until valve has undergone 2500 cycles.

(d) After each 50 cycles, stem and seat leakage shall be checked.

(e) Seating, unseating, and running torques shall be noted during this test. Maximum valves should be within those listed in manufacturer’s published data.

No lubrication shall be applied to the stem seal either before or during these tests.

S1.1.2 Pressurization Rate Test—With a test pressure equal to the 100°F (38°C) pressure rating applied upstream, and a depressurized downstream volume as specified in 6.1.15, the valve shall be operated to demonstrate its ability to meet the pressurization rate specified in 6.1.15.

S1.1.3 Shock Test—The valve shall be subjected to and meet the high-impact shock tests for Grade A, Class I as specified in MIL-S-901, pressurized with water, air, or nitrogen. The valve inlet shall be pressurized to a test pressure of the 100°F (38°C) pressure rating. There shall be no structural damage to the valve. There shall be no degradation to the performance capability of the valve.

S1.1.4 Vibration Test—The valve shall be vibration tested in accordance with Type I of MIL-STD-167-1 pressurized with air or nitrogen. The valve inlet shall be pressurized to the 100°F (38°C) pressure rating. At frequencies up to and including 33 Hz (unless otherwise specified in the ordering information, Section 5), there shall be no resonance in the range of frequency tested. There shall be no structural damage or degradation to the performance capability of the valve.

S1.1.5 Noise Test—The valve shall be tested for airborne noise in accordance with MIL-STD-740-1. The noise (sound pressure level) shall not exceed 85 db, unless otherwise specified in 5.0, observed at one-metre distance from the valve.

S1.1.6 Post-Test Examination—After completion of each or all of the tests specified in S1.1.1 through S1.1.5, the valve shall be disassembled and examined for any evidence of excessive wear, degradation, or impending damage or breakage.

S2. Technical Data Requirements

S2.1 Drawings—Assembly drawings or catalog sheets of the valve which clearly depict design shall be provided. The following information shall also be included as part of the drawings or catalog sheets:

S2.1.1 Bill of material listing specification, grade, condition, and any other data required to fully identify the properties of the materials proposed. This shall include identifications, material and size designations, shore hardness, and any other data necessary to fully identify the parts.

S2.1.2 In cases in which standard commercial or military parts are or can be used, these shall be appropriately identified.

S2.1.3 Outline dimensions, disassembly space, location, and size of end connections.

S2.1.4 Estimated weight and center of gravity (vertical, longitudinal, and transverse).

S2.1.5 Recommended assembly torques or equivalent procedures for making up all joints and threaded assemblies.

S2.2 Technical Manuals—Technical manuals shall provide a description, installation procedures, operation and maintenance instructions, and illustrated parts breakdown for the valve, organized as follows:

S2.2.1 Chapter 1—General Information and Safety Precautions.

S2.2.2 Chapter 2—Operation.

S2.2.3 Chapter 3—Functional Description.

S2.2.4 Chapter 4—Scheduled Maintenance.

S2.2.5 Chapter 5—Troubleshooting.

S2.2.6 Chapter 6—Corrective Maintenance.

S2.2.7 Chapter 7—Parts List.

S2.2.8 Chapter 8—Installation.

S2.3 In addition, the following shall be included as part of the technical manual content:

S2.3.1 The assembly drawings for the valve, supplemented by additional illustrations where necessary to adequately illustrate operation and maintenance. These additional illustrations may consist of blowouts, partial or full sections, and may eliminate extraneous lines and details to clarify the interaction of parts.

S2.3.2 Table listing wrench sizes and assembly torques (or other equivalent procedures) for making up all joints and threaded assemblies.

S2.3.3 Detailed disassembly and reassembly procedures. In addition to a section providing procedures for the complete disassembly and reassembly of the valve, maintenance, and troubleshooting sections shall contain, or refer to, only the limited disassembly and reassembly required to accomplish each particular operation. This is intended to reduce the possibility of unnecessary disassembly and unnecessary disturbance of adjustments when performing specific or limited maintenance or troubleshooting operations.

S3. Quality Assurance

S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.

S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.

S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection, and quality assurance instructions, and illustrated parts breakdown for the valve.
control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.

S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.

S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications, and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.

S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.

S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system which identified inspection status of material throughout all stages of manufacture.

S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions utilizing documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.

S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examinations and inspections.

S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.

S3.11 Nondestructive Examination—Provisions shall be made to utilize non-destructive examination, as necessary, to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer and/or qualified by a recognized national body, and their authorizations/qualification records shall be made available to the inspection authority if required.

S3.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.

S3.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatments have been applied. Means should be provided by which heat treatment requirements can be verified.

S3.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during all stages of manufacture and shall be able to distinguish between inspected and noninspected material.

S3.15 Calibration of Measurement and Test Equipment—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring, and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S3.16 Records Maintenance—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S3.17 Sample Forms—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S3.18 Inspection Authority—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

S4. Special Material, Design, and Performance Considerations

S4.1 Recovered Materials—Unless otherwise specified in this specification, all equipment, material, and articles incorporated in the products covered by this specification shall be new and may be fabricated using materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. The term “recovered materials” means materials that have been collected or recovered from solid waste and reprocessed to become a source of raw materials, as opposed to virgin raw materials. None of the above shall be interpreted to mean that the use of used or rebuilt products is allowed under this specification unless otherwise specifically specified.

S4.2 Pipe threads shall not be used in the construction of the valve.
Standard Specification for Pressure-Reducing Valves for Air or Nitrogen Systems

This standard is issued under the fixed designation F 1795; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the design, construction, testing, and operating requirements for self-contained pressure-reducing valves for air or nitrogen systems.

1.2 The values stated in this specification in inch-pounds units are to be regarded as the standard. The SI equivalent shown in parentheses are provided for information only.

3. Terminology

3.1 Definitions:
3.1.1 accuracy of regulation—the amount by which the downstream pressure may vary when the pressure-reducing valve is set at any pressure within the required set pressure range and is subjected to any combination of inlet pressure, flow demand, and ambient temperature variations within the specified limits.
3.1.2 bubble-sight—no visible leakage over a 3-min period using either water submersion or the application of bubble fluid for detection.
3.1.3 external leakage—leakage from the pressure-reducing valve which escapes to atmosphere.
3.1.4 fail-open flow capacity—the ability of the pressure-reducing valve to pass flow under any given set of pressure conditions when, as a result of mechanical failure, it has assumed a position of least resistance to flow.
3.1.5 flow capacity—the ability of the pressure-reducing valve to pass flow under any given set of pressure conditions.
3.1.6 flow rate demand—the amount of flow demanded by the system at any given time downstream of the pressure-reducing valve.
3.1.7 flow rate demand range—the range over which the flow demand can vary.
3.1.8 hydrostatic shell test pressure(s)—The hydrostatic test pressures that the inlet and outlet of the pressure-reducing valve is required to withstand without damage. Pressure-reducing valve operation is not required during application of shell test pressure, but the pressure-reducing valve must meet all performance requirements after the shell test pressure has been removed.
3.1.9 inlet operating pressure range—the range over which the inlet pressure supplied to the pressure-reducing valve can vary under any operational conditions which the pressure-reducing valve can be subjected to in service.
3.1.10 operating pressure(s)—the pressures within the pressure-reducing valve during service.

3.1.11 pressure ratings—the pressure ratings of the pressure-reducing valve shall be as defined in the documents listed in Table 1. The pressure ratings (also called pressure-temperature ratings) establish the maximum allowable working (service) pressures of a component (valve, end connections, and so forth) at various temperatures. For a pressure-reducing valve, the pressure ratings may not be identical for the valve inlet and outlet.

3.1.12 pressure-reducing valve—a component which accomplishes automatic regulation of the downstream pressure. In this component, the upstream pressure is reduced to the desired downstream pressure.

3.1.13 pressure reversal—a condition in which pressure exists at the outlet of a pressure-reducing valve when the loading element is deactivated (set spring adjustment backed off fully or dome charge vented off completely) and inlet pressure is vented off.

3.1.14 seat-tightness—the ability of the pressure-reducing valve to prevent leakage from the valve inlet to the valve outlet.

3.1.15 self-contained pressure-reducing valve—a pressure-reducing valve that does not use an external power source, such as compressed air, electricity, or hydraulic fluid for operation, but instead uses the line fluid for operation.

3.1.16 set pressure—the outlet pressure delivered by the pressure-reducing valve at the time the pressure setting is made. For the purposes of this specification, it will be assumed that the setting is made when there is no flow demand on the pressure-reducing valve (“lock-up” condition), and the pressure-reducing valve is at surrounding ambient temperature.

3.1.17 set pressure range—the range of set pressures (set pressure limits) over which the pressure-reducing valve can be adjusted while meeting the performance requirements specified.

3.1.18 soft-seating insert—the insert, incorporated in either the poppet or the seat of the pressure-reducing valve, which ensures bubble-tight seat tightness under all operating conditions.

3.1.19 valve poppet—the part of the pressure-reducing valve trim which established a rate of flow by moving toward or away from the valve seat.

4. Classification

4.1 Pressure-reducing valves shall be of the following types, sizes, pressure ratings, and end connections, as specified in Section 5.

4.1.1 Types—Pressure-reducing valves shall be either Type I (inlet outlet end connections of the same pressure rating) or Type II (outlet end connection pressure rating lower than the inlet end connection rating) and specified in Section 5.

4.1.2 Sizes—Pressure-reducing valve sizes shall be 1/8 NPS (10.2 mm), 1/4 NPS (13.5 mm), 1/8 NPS (17.2 mm), 1/2 NPS (21.3 mm), 3/4 NPS (26.9 mm), 1 NPS (33.7 mm), 1 1/4 NPS (42.4 mm), 1 1/2 NPS (48.3 mm), and 2 NPS (60.3 mm).

4.1.3 Pressure Ratings—Pressure-reducing valves shall have pressure rating(s) selected (see 3.1) from Table 1. The pressure rating(s) selected shall be specified in Section 5.

4.1.4 End Connections—Pressure-reducing valves shall have end connections selected from those listed in Table 1 and specified in Section 5.

5. Ordering Information

5.1 Ordering documentation for pressure-reducing valves under this specification shall include the following information as required to describe the equipment adequately.

5.1.1 ASTM designation and year of issue,
5.1.2 Valve type (see 4.1.1),
5.1.3 Valve inlet and outlet sizes (see 4.1.2),
5.1.4 Pressure rating(s) (see 4.1.3),
5.1.5 Type of end connections (see 4.1.4),
5.1.6 Inlet operating pressure range.
5.1.7 Set pressure and set pressure range, if other than specified (see 7.1.3).
5.1.8 Flow rate demand range (see 7.1.1, S1.1.2).
5.1.9 Accuracy of regulation required, if set pressure is below 10 psig (see 7.1.2).
5.1.10 Tamper-proof set-point adjustment, if required (see 6.1.9).
5.1.11 Supplementary requirements, if any (S1 through S4).
5.1.12 Maximum vibration frequency and displacement amplitude, if other than specified (see S1.1.4).

6. Valve Construction

6.1 Valves shall incorporate the design features specified in 6.1.1-6.1.19.

6.1.1 General Requirements—Pressure-reducing valves shall be self-contained, requiring no external power source for operation. The pressure-reducing valve shall be capable of

\(^a\)For union inlet and outlet end connections, only the pertinent dimensions listed in the applicable documents (Military Specification or NAVSEA requirements) shall apply. The valve shall be supplied with the thread pieces only, without the tail pieces and union nuts.
meeting all requirements of this specification and provide extended reliable operation when protected by a 5-µm nominal/18-µm absolute filter installed upstream and when subjected to conditions specified in Section 5.

6.1.2 *Materials of Construction*—Material requirements for the pressure-reducing valve shall be as follows: The pressure containing envelope (body, gas dome, or spring housing) shall be 300 series corrosion-resistant steel (304, 304L, 316, or 316L). Internal parts including springs, poppets, seal rings, and retainers shall be 300 series corrosion-resistant steel, nickel-aluminum bronze, nickel-copper (70–30), or bronze. Other materials for both the pressure-containing envelope and internal parts may be selected to assure compatibility with the line medium, weldability, and to provide corrosion resistance without requiring painting, coating, or plating. Materials for contacting parts shall be selected to minimize electrolytic corrosion and galling.

6.1.3 *Pressure Envelope*—The pressure-reducing valve shall be designed to pass a hydrostatic shell test at pressure(s) of at least 1.5 times the 100°F (38°C) pressure rating(s) of the valve without damage.

6.1.4 *Port Configuration*—The pressure-reducing valve shall have in-line inlet and outlet ports.

6.1.5 *Pressure Lines*—All pressure lines in the pressure-reducing valve shall be internally ported.

6.1.6 *Soft-Seating Insert*—A field replaceable soft-seating insert shall be incorporated in the pressure-reducing valve. Soft-seating inserts shall be protected from direct flow impingement, excessive loading and extrusion, or any other effect jeopardizing their useful life. Soft-seating inserts shall be of the simplest practical configuration to facilitate emergency replacement manufacture where necessary.

6.1.7 *Joints*—The bonnet or spring housing and bottom cap shall be attached to the body by bolting, a threaded connection, or a threaded union connection.

6.1.8 *Springs*—Any spring incorporated in the pressure-reducing valve shall not be compressed solid during operation. Spring ends shall be squared and ground. Engagement or disengagement of parts against spring compression shall not be permitted.

6.1.9 *Set Point Adjustment*—For mechanical spring-loaded pressure-reducing valves, the set point shall be adjustable under pressure and shall incorporate right-hand threads so that a clockwise rotation increases the set pressure. Means shall be used to prevent an accidental or inadvertent change in set pressure. The option of a tamper-proof set point adjustment shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used. Any exposed threads shall be protected by plastic caps for shipping.

6.1.10 *Gas Dome*—For gas-dome loaded pressure-reducing valves, the set point shall be adjustable under pressure and shall maintain its charge without adjustment or recharge more frequently than once a year to remain within its specified performance envelope. Upstream pressure shall be used to establish dome load. Dome loading shall be accomplished by two valves installed in series, with a bleed-off valve in-between. If these valves are metal seated, they shall not seat directly into the structure of the dome so that damage or wear to the seating surfaces would not require repair or replacement of the dome. Only a single dome penetration is allowed. The valves shall be operable by a standard-size hex wrench or other suitable means. There shall be no external leakage past the threads during dome bleeding. Flow from the bleed-off valve shall be ported in such a way that it does not impinge directly on the person making the adjustment, cause excessive noise, or potentially lead to ice formation within the dome loading circuit.

6.1.11 *Threads*—Threads shall be as specified in ANSI B1.1. Where necessary, provisions shall be incorporated to prevent the accidental loosening of threaded parts. The design shall be such that standard wrenches can be used on all external bolting. Lock-wire shall not be used. Any exposed threads shall be protected by plastic caps for shipping.

6.1.12 *Accessability*—All internal parts of the pressure-reducing valve shall be accessible for adjustment or service, without removing the pressure-reducing valve from the line.

6.1.13 *Interchangeability*—The pressure-reducing valve including all associated piece parts, shall have part number identity, and shall be replaceable from stock or the manufacturer on a nonselective and random basis. Parts having the same manufacturer’s part number shall be directly interchangeable with each other with respect to installation (physical) and performance (function). Physically interchangeable assemblies, components, and parts are those that are capable of being readily installed, removed, or replaced without alternation, misalignment or damage to parts being installed or to adjoining parts. Fabrication operations such as cutting, filing, drilling, reaming, hammering, bending, prying, or forcing shall not be required.

6.1.14 *Nonmetallic Element Interchangeability*—Nonmetallic elements, including but not limited to, soft-seating inserts, cushions, and O-rings, shall be treated as separately identified and readily replaceable parts.

6.1.15 *Maintainability*—Maintenance shall require standard tools to the maximum extent possible. Any special tools required for maintenance shall be identified, and shall be supplied as part of the valve.

6.1.16 *Reversibility*—Seating inserts shall not be physically reversible unless they are also functionally reversible to preclude incorrect assembly.

6.1.17 *Adjustments*—There shall be no adjustments required in the pressure-reducing valve during or after assembly other than the set point.

6.1.18 *Pressure Reversal*—The pressure-reducing valve shall not be damaged when subjected to a maximum pressure reversal (maximum set pressure exists at the outlet).

6.1.19 *Guiding*—The valve poppet shall be guided to prevent binding or seizing and ensure proper seating under all operating conditions. Proper alignment of all internal operating parts shall be maintained with interchangeable parts and under all tolerance stack-up conditions.

7. **Performance Requirements**

7.1 Pressure-reducing valves shall meet the performance requirements of 7.1.1–7.1.5.

7.1.1 *Flow Rate Demand Range*—The maximum and minimum flow rate demand required shall be specified (see Section
5) in standard cubic feet per minute [at 60°F (16°C) and 14.7 psia (101 kPa)]. The pressure-reducing valve shall meet the specified maximum and minimum flow rate demand requirements, or any intermediate flow rate demand requirement, and shall operate without hunting or chattering under all specified conditions.

7.1.2 Accuracy of Regulation—The pressure-reducing valve shall maintain set pressure within the accuracy of regulation limits specified in Table 2 under all flow rate demand and inlet operating pressure conditions specified.

7.1.3 Set Pressure Range—The set pressure range shall be as follows: Where the pressure-reducing valve is mechanically spring loaded, the set pressure shall be adjustable through a range of at least ±5% of the set pressure, or ±2 psi (13.8 kPa), whichever is greater. Where the pressure-reducing valve is gas dome loaded, the set point shall be adjustable through a range of at least ±25% of the set pressure or 10 psi (68.9 kPa), whichever is greater.

7.1.4 Seat Tightness—The pressure-reducing valve shall meet the seat tightness requirements of 8.1.3. Where necessary, leakage measurement shall start after temperature stabilization.

7.1.5 External Leakage—Pressure-reducing valve external leakage shall be bubble tight at operating pressure conditions over a 3-min period.

8. Tests Required

8.1 Each pressure-reducing valve must pass the tests outlined in 8.1.1-8.1.4.

8.1.1 Visual Examination—The pressure-reducing valve shall be examined visually to determine conformance with the ordering data, interface dimensions, and workmanship without disassembly.

8.1.2 Hydrostatic Shell Test—The pressure-reducing valve shall be hydrostatically tested with water by applying test pressure(s) not less than 1.5 times the 100°F (38°C) pressure rating(s) to the inlet and outlet ports to check structural integrity. Test pressure(s) shall be applied for 3 min. Air or nitrogen may be used in lieu of water, providing appropriate safety precautions are taken to minimize the risk associated with the use of a compressible fluid. There shall be no external leakage, permanent distortion, or structural failure.

8.1.3 Seal Tightness Test—The pressure-reducing valve shall be tested for seat tightness with air or nitrogen gas at an inlet test pressure not less than the maximum inlet operating pressure. The valve shall be isolated downstream using a dead-ended volume not exceeding ten diameters of downstream pipe and monitored with bubble fluid to assure tightness. There shall be no detectable rise in the outlet pressure over a 3-min period after pressure-reducing valve temperature stabilizes.

8.1.4 External Leakage Test—Air or nitrogen gas shall be applied to the inlet of the pressure-reducing valve at the rated pressure. External leakage shall be checked using bubble fluid or by submerging the pressure-reducing valve in water. There shall be no visible external leakage over a 3-min period.

9. Marking

9.1 Identification Plate—An identification plate of corrosion-resistant metal in accordance with Specification F 992, Types I, II, III, or IV shall be permanently attached to the pressure-reducing valve and shall include the following information (some or all information may instead be stamped or etched directly on the outside surface of the pressure-reducing valve):

9.1.1 Manufacturer’s name,
9.1.2 ASTM designation and year of issue,
9.1.3 Valve size, type, and pressure rating(s),
9.1.4 Nominal operating conditions (inlet pressure, set pressure, and flow capacity),
9.1.5 Manufacturer’s model/part number.

10. Quality Assurance System

10.1 The manufacturer shall establish and maintain a quality assurance system that will ensure all the requirements of this specification are satisfied. This system shall also ensure that all valves will perform in a similar manner to those representative pressure-reducing valves subjected to original testing for determination of the operating and flow characteristics.

10.2 A written description of the quality assurance system the manufacturer will use shall be available for review and acceptance by the inspection authority.

10.3 The purchaser reserves the right to witness the production tests and inspect the pressure-reducing valves in the manufacturer’s plant to the extent specified on the purchase order.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements S1, S2, or S4 shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of those supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. Supplemental Tests

S1.1 Qualification tests shall be conducted at a facility satisfactory to the customer and shall consist of the examinations and tests selected from those specified in S1.1.1 through S1.1.7 and delineated in the ordering data. The tests may be conducted on representative valve sizes and pressure classes to qualify all sizes and pressure classes of valves, provided the valves are of the same type and design. Evidence of prior approval of these tests is acceptable.

S1.1.1 Pressure Reversal Test—The pressure-reducing valve shall be tested to determine the susceptibility to damage when subjected to pressure reversal as specified in 6.1.18. It shall be set up with maximum inlet operating pressure and maximum set pressure. A separate means shall be included to insure that there is no loss of downstream pressure during this test. The reference load shall then be removed from the set-point mechanism (if the pressure-reducing valve is spring loaded, all spring compression shall be backed off, if it is gas dome loaded, all dome charge shall be released). The inlet pressure shall then be released and this condition (no load on the pressure-reducing valve set point mechanism, zero pressure applied to the inlet side of the pressure-reducing valve seat, and maximum set pressure applied to the outlet side of the pressure-reducing valve seat) shall be maintained for a period of not less than 1 h. There shall be no leakage from the outlet to the inlet of the pressure-reducing valve seat) shall be maintained for a period of not less than 1 h. There shall be no leakage from the outlet to the inlet of the pressure-reducing valve seat. There shall be no evidence of damage to the pressure-reducing valve and no degradation to its performance capability.

S1.1.2 Accuracy of Regulation Test—The pressure-reducing valve shall be tested for accuracy of regulation at each inlet pressure/set pressure combination shown in Table S1.1. At Condition D, flow shall be varied over the full range of flow rate demand as specified in Section 5. For Conditions A, B, and C, full flow range testing is not required. During each sequence (changing from Condition A to Condition B and changing from Condition C to Condition D), no alteration shall be made to the set pressure adjustment, or any other portion of the pressure-reducing valve, and the accuracy of regulation shall be maintained as required by Table 2. There shall be no instability or other evidence of unsatisfactory operation of pressure-reducing valve during these tests. Flow in each condition shall be maintained long enough to demonstrate that the above requirements are met.

S1.1.3 Shock Test—The pressure-reducing valve shall be subjected to and meet the high-impact shock tests for Grade A, Class I as specified in MIL-S-901 pressurized with air or nitrogen gas. The inlet port shall be pressurized to the maximum inlet operating pressure and the outlet port pressurized to the maximum outlet operating pressure. There shall be no structural damage to the pressure-reducing valve or any components. There shall be no degradation to the performance capability of the pressure-reducing valve. Momentary loss in pressure is permissible.

S1.1.4 Vibration Test—The pressure-reducing valve shall be vibration tested in accordance with Type 1 of MIL-STD-167-1 pressurized with air or nitrogen gas. The inlet port shall be pressurized to the maximum inlet operating pressure and the outlet port pressurized to the maximum outlet operating pressure. At frequencies up to and including 33 Hz (unless otherwise specified in Section 5), there shall be no resonance in the range of frequency tested. There shall be no structural damage or degradation to the performance capability of the pressure-reducing valve.

S1.1.5 Noise Test—The pressure-reducing valve shall be tested for airborne noise in accordance with MIL-STD-740-1. The noise (sound pressure level) shall not exceed 85 db observed at 1-m distance from the pressure-reducing valve.

S1.1.6 Posttest Examination—The pressure-reducing valve shall be disassembled and examined for any evidence of excessive wear, degradation, or impending damage or breakage.

S1.1.7 Spring Deflection Test—The springs used in the pressure-reducing valves shall not exhibit a permanent set when compressed 20 % beyond their design limits. A spring deflection test shall be conducted to verify compliance to this requirement.

S2. Technical Data and Certification Requirements

S2.1 Drawings—Assembly drawings or catalog sheets of the pressure-reducing valve that clearly depict design and shall be provided. The following information shall also be included as part of the drawings or catalog sheets:

S2.1.1 Bill of material listing specification, grade, condition, and any other data required to identify fully the properties of the materials proposed. This shall include identifications, material and size designations, shore hardness and any other data necessary to identify fully the parts.

S2.1.2 In cases in which standard commercial or military parts are or can be used, these shall be appropriately identified.

S2.1.3 Outline dimensions, disassembly space, location, and size of end connections.

S2.1.4 Estimated weight and center of gravity (vertical, longitudinal, and transverse).
S2.1.5 Recommended assembly torques or equivalent procedures for making up all joints and threaded assemblies.
S2.1.6 The following valve performance information shall be included:
S2.1.6.1 Set pressure and adjustable range.
S2.1.6.2 Specified operating conditions—range of inlet pressures and required range of capacity.
S2.1.6.3 Fail-open capacity (for purposes of pressure-relief valve sizing) of the pressure-reducing valve.
S2.2 Technical Manuals—Technical manuals shall provide a description, installation procedures, operation and maintenance instructions, and illustrated parts breakdown for the pressure-reducing valve, organized as follows:
S2.2.1 Chapter 1—General Information and Safety Precautions.
S2.2.2 Chapter 2—Operation.
S2.2.3 Chapter 3—Functional Description.
S2.2.4 Chapter 4—Scheduled Maintenance.
S2.2.5 Chapter 5—Troubleshooting.
S2.2.6 Chapter 6—Corrective Maintenance.
S2.2.7 Chapter 7—Parts List.
S2.2.8 Chapter 8—Installation.
S2.2.9 In addition, the following shall be included as part of the technical manual content:
(a) The assembly drawings for the pressure-reducing valve, supplemented by additional illustrations where necessary to illustrate operation and maintenance adequately. These additional illustrations may consist of blowouts, partial or full sections, and may eliminate extraneous lines and details to clarify the interaction of parts.
(b) Table listing wrench sizes and assembly torques or other equivalent procedures for making up all joints and threaded assemblies.
(c) Detailed disassembly and reassembly and procedures. In addition to a section providing procedures for the complete disassembly and reassembly of the pressure-reducing valve, maintenance and troubleshooting sections shall contain, or refer to, only the limited disassembly and reassembly required to accomplish each particular operation. This is intended to reduce the possibility of unnecessary disassembly and unnecessary disturbance of adjustments when performing specific or limited maintenance or troubleshooting operations.
S2.3 Certification—Certification shall be provided indicating that the valve meets all requirements of the purchase order.

S3. Quality Assurance
S3.1 Scope of Work—The written description of the quality assurance system shall include the scope and locations of the work to which the system is applicable.
S3.2 Authority and Responsibility—The authority and responsibility of those in charge of the quality assurance system shall be clearly established.
S3.3 Organization—An organizational chart showing the relationship between management and the engineering, purchasing, manufacturing, construction, inspection and quality control groups is required. The purpose of this chart is to identify and associate the various organizational groups with the particular functions for which they are responsible. These requirements are not intended to encroach on the manufacturer’s right to establish, and from time to time to alter, whatever form of organization the manufacturer considers appropriate for its work. Persons performing quality control functions shall have a sufficiently well-defined responsibility and the authority and the organization freedom to identify quality control problems and to initiate, recommend, and provide solutions.
S3.4 Review of Quality Assurance System—The manufacturer shall ensure and demonstrate the continuous effectiveness of the quality assurance system.
S3.5 Drawings, Design Calculations, and Specification Control—The manufacturer’s quality assurance system shall include provisions to ensure that the latest applicable drawings, design calculations, specifications and instructions, including all authorized changes, are used for manufacture, examination, inspection, and testing.
S3.6 Purchase Control—The manufacturer shall ensure that all purchased material and services conform to specified requirements and that all purchase orders give full details of the material and services ordered.
S3.7 Material Control—The manufacturer shall include a system for material control that ensures the material received is properly identified and that any required documentation is present, identified to the material, and verifies compliance to the specified requirements. The material control system shall ensure that only the intended material is used in manufacture. The manufacturer shall maintain control of material during the manufacturing process by a system which identifies status of material throughout all stages of manufacture.
S3.8 Manufacturing Control—The manufacturer shall ensure that manufacturing operations are carried out under controlled conditions using documented work instructions. The manufacturer shall provide for inspection, where appropriate, for each operation that affects quality or shall arrange an appropriate monitoring operation.
S3.9 Quality Control Plan—The manufacturer’s quality control plan shall describe the fabrication operations, including examination and inspections.
S3.10 Welding—The quality control system shall include provisions for ensuring that welding conforms to specified requirements. Welders shall be qualified to the appropriate standards and the qualification records shall be made available to the inspection authority if required.
S3.11 Nondestructive Examination—Provisions shall be made to use nondestructive examination, as necessary, to ensure that material and components comply with the specified requirements. Nondestructive examinations shall be authorized by their employer and/or qualified by a recognized national body, and their authorizations/qualification records shall be made available to the inspection authority if required.
S3.12 Nonconforming Items—The manufacturer shall establish procedures for controlling items not in conformance with the specified requirements.
S3.13 Heat Treatment—The manufacturer shall provide controls to ensure that all required heat treatment have been applied. Means should be provided by which heat treatment requirements can be verified.
S3.14 Inspection Status—The manufacturer shall maintain a system for identifying the inspection status of material during
all stages of manufacture and shall be able to distinguish between inspected and non-inspected material.

S3.15 *Calibration of Measurement and Test Equipment*—The manufacturer shall provide, control, calibrate, and maintain inspection, measuring, and test equipment to be used in verifying conformance to the specified requirements. Such calibration shall be traceable to a national standard and calibration records shall be maintained.

S3.16 *Records Maintenance*—The manufacturer shall have a system for the maintenance of inspection records, radiographs, and manufacturer’s data reports that describe the achievement of the required quality and the effective operation of the quality system.

S3.17 *Sample Forms*—The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description of the quality assurance system shall make reference to these forms.

S3.18 *Inspection Authority*—The manufacturer shall make available to the inspection authority at the manufacturer’s plant a current copy of the written description of the quality assurance system. The manufacturer’s quality assurance system shall provide for the inspection authority at the manufacturer’s plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the inspection authority to perform its duties in accordance with this supplementary requirement. The manufacturer may provide for such access by furnishing the inspection authority with originals or copies of such documents.

S4. **Special Material, Design, and Performance Requirements**

S4.1 *Recovered Materials*—Unless otherwise specified herein, all equipment, material, and articles incorporated in the products covered by this specification shall be new and may be fabricated using materials produced from recovered materials to the maximum extent practicable without jeopardizing the intended use. The term “recovered materials” means materials that have been collected or recovered from solid waste and reprocessed to become a source of raw materials, as opposed to virgin raw materials. None of the above shall be interpreted to mean that the use of used or rebuilt products is allowed under this specification unless otherwise specified.

S4.2 Pipe threads shall not be used in the pressure-reducing valve.

S4.3 *Envelope Dimensions*—Pressure-reducing valve envelope dimensions (see X1.5) shall be as specified in Fig. 1 and Table S4.1.

S4.4 *Nonmetallic Valve Internal Parts*—Nonmetallic internal parts shall be compatible with any residual materials (100% humidity, entrained salt spray, and 2190 TEP lubricating oil used in air compressors) in the line media.

---

**FIG. 1 Pressure−Reducing Valve Envelope Dimensions**
APPENDIX

(Nonmandatory Information)

X1. GUIDELINES FOR SELECTION OF PRESSURE-REDUCING VALVES

X1.1 Scope—This appendix provides general guidelines for the selection of pressure-reducing valves, and therefore, its use does not in any way relieve the user of the final responsibility in the selection and installation of pressure-reducing valves.

X1.2 Mode of Operation—Pressure-reducing valves for air or nitrogen service are commonly designed to operate in one of three basic modes:

X1.2.1 Direct Spring Loaded—Set point established by a mechanical spring; generally practical at only small-to-moderate combinations of flow demand and set pressure.

X1.2.2 Gas Dome Loaded—Set point established by a fixed gas charge loaded into the dome from the valve inlet at the time the valve is set; generally advantageous for high combinations of flow demand and set pressure.

X1.2.3 Gas Dome Loaded, Pilot Referenced—Set point established by a charge of gas in the dome which is maintained constant at all times by a spring-loaded pilot valve installed on or adjacent to the dome and which operates by sensing the pressure in the dome and either venting the dome, or charging the dome, using gas drawn from the valve inlet, as necessary. This arrangement, also known as a compensator, compensates for temperature change, valve stroke, leakage, or any other condition which would otherwise cause a change in dome pressure and thus set point.

X1.3 Fail-Open Capacity—It is critical to establish accurately and define clearly the fail-open capacity of a pressure-reducing valve. This parameter establishes the requirements for the pressure-relief valve that protects the system downstream of the pressure-reducing valve from overpressure in the event of pressure-reducing valve failure.

X1.4 Valve Types—Pressure-reducing valves covered by this specification are defined by type as follows:

X1.4.1 Type 1—Valves that have inlet and outlet connections that are identical.

X1.4.2 Type 2—Valves that have inlet and outlet connections that are not identical. These valves can facilitate any configuration, increase in size, or decrease in rating downstream of the regulator as a result of the pressure reduction in the flow path accomplished by the pressure-reducing valve.

X1.5 Pressure-reducing valves intended for use in manifolds per the applicable ASTM specification on manifolds (Specification F 1685), should be Type I, with union end connections in accordance with Table 1 and envelope dimensions in accordance with Fig. 1 and Table S4.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).
Standard Guide for  
Shipboard Generated Waste Management Audits

This standard is issued under the fixed designation F 1799; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 Purpose—This guide covers information for assisting shipowners in planning for costs or scheduling complications during maintenance, repair, modifications, purchase negotiations, or scrapping activities. Removal and disposal of certain materials disturbed during modification, maintenance, or disposal of systems or components may be costly or interrupt the work schedule.

1.2 Objectives:

1.2.1 This guide will describe materials that may be disturbed on ships during maintenance or scrapping activities, which may result in costly or time-consuming removal or disposal actions.

1.2.2 This guide will provide a systematic method to identify and record the locations of materials of concern for immediate planning and future reference.

1.2.3 This guide will include a brief discussion of issues related to the handling and storage of materials described in this guide.

1.3 Considerations Beyond Scope:

1.3.1 This guide is not intended to address materials carried as cargo or material stored onboard in prepackaged containers.

1.3.2 This guide is not intended to address waste products related to the ongoing, day-to-day operation of a ship, such as sewage, solid waste, incinerator ash (or other residual products resulting from solid waste treatment), and residual sludge left in segregated ballast tanks.

1.3.3 This guide does not provide a comprehensive index of test methods available for characterizing the materials discussed. Test methods referenced or described should be considered as examples.

1.3.4 This guide is not intended to address directly regulatory issues for any of the materials described.

1.3.5 This guide is not intended to address remediation concerns.

E 849 Practice for Safety and Health Requirements Relating to Occupational Exposure to Asbestos

2.2 ASHRAE Standards: 4

ASHRAE Guideline 3, Reducing Emission of Fully Halogenated Chlorofluorocarbon (CFC) Refrigerants in Refrigeration and Air-Conditioning Equipment and Applications

2.3 EPA Methods: 5

EPA 600/M4–82–020, Interim Method of the Determination of Asbestos in Bulk Insulation Samples
EPA SW-846, Method 8080, Organochlorine Pesticides and PCBs
EPA SW-846, Method 1311, Toxicity Characteristic Leachate Procedure
EPA SW-846, Method 8270, Semi-Volatiles List
EPA SW-846, Method 8260, Volatiles List

3. Terminology

3.1 Definitions of Terms Specific to This Standard:

3.1.1 audit, n—a process to identify waste materials associated with maintenance, repair, modifications, purchase negotiations, or scrapping activities, some of which may be hazardous, with the goal of providing planning information about environmental, health, and safety risks and related costs.

3.1.2 friable, adj—a physical state in which a dry material can be easily crumpled, pulverized, or reduced to powder by hand pressure.

3.1.3 mobile, adj—capable of being transported from one surface to another.

---

2 For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For Annual Book of ASTM Standards volume information, refer to the standard’s Document Summary page on the ASTM website.

3 Withdrawn.

4 Available from American Society of Heating, Refrigerating, and Air-Conditioning Engineers, Inc. (ASHRAE), 1791 Tullie Circle, NE, Atlanta, GA 30329.

3.1.4 PCB, \( n \)—a class of chemicals comprised of polychlorinated biphenyls.

3.1.5 streaming agents, \( n \)—a type of chemical used to fight small, contained fires by directing the firefighting agent specifically at the fire.

3.1.6 target materials, \( n \)—specific materials that the audit process will identify for evaluation.

3.1.7 waste oil, \( n \)—oil that cannot be reused or recycled.

4. Significance and Use

4.1 Applicability—This guide is intended to describe a planning audit that will improve the shipowner’s ability to forecast costs and schedule impacts and aid the shipowner in identifying environmental, health, and safety concerns associated with the removal, handling, and disposal of potentially hazardous shipboard materials.

4.2 Use—Audits may be performed to aid in planning for a variety of events, including maintenance, repair, modification, purchase, or scrapping. To maximize efficiency, audits should be tailored to meet the specific needs of the shipowner, with target materials identified during the planning process.

4.3 Caution—Legal restrictions on the removal and disposal of materials discussed in this guide may vary significantly from port to port, both within the United States and abroad. Reasons for this variation include the decentralized nature of port control, state, and local environmental regulations, and the local availability of landfill or treatment facilities. Users of this guide should consult local authorities to obtain information on specific legal requirements.

5. Procedure

5.1 Planning—Objectives for the waste management audit should be established at the planning stage. A well-planned audit will focus on target materials in critical locations to minimize audit costs. Waste management audits, therefore, should be performed by environmental, health, and safety experts familiar with the specific objectives of the audit. Past audit reports of the area and other documentation that may provide insight into material characterization should be reviewed to avoid the expense of unnecessary tests. For example, construction specifications may characterize a particular material, eliminating the need for testing. In some instances, inspection of the ship or interviews with personnel on-site may be beneficial in planning the audit.

5.2 Testing—Many materials will require sampling and characterization tests. A sampling plan should be followed by qualified and authorized personnel. Analysis performed by a qualified or certified laboratory may be required.

6. Potential Shipboard Generated Wastes

6.1 Asbestos:

6.1.1 Description—Asbestos is the common name of a number of substances including amosite, anthrophyllite, amphibole, and chrysotile (1). When asbestos becomes friable, it may be inhaled or swallowed, penetrating body tissues and remaining there for many years. Exposure to asbestos has been linked to asbestososis, mesothelioma, and other cancers. Exposure to cigarette smoke may increase the long-term risk of developing asbestos-related lung cancer by as much as 90%.

6.1.2 Uses—Many common construction products contain asbestos, although use of the material in the United States was significantly reduced during the 1970s. Likely products include pipe lagging and other types of insulation, vinyl tile and linoleum, floor tile adhesives, cement sheet and fiberboard, brake pads and linings, and gasket materials, particularly for high-temperature applications.

6.1.3 Test Methods (for Thermal Insulation) (2):

6.1.3.1 Sampling—The area to be sampled should be subdivided into homogeneous areas, and sampling of each homogeneous area should be conducted in a statistically random manner. For surface materials, collect at least three samples for each area under 1000 ft\(^2\), at least five for areas between 1000 and 5000 ft\(^2\), and at least seven for each area greater than 5000 ft\(^2\). For piping insulation, collect at least three samples from each homogeneous section of piping.

6.1.3.2 Analysis—Samples should not be composited for analysis. Analysis of each sample should be conducted using the Polarized Light Microscopy Method described in EPA 600/M4-82-020. Under current U.S. regulations, a homogeneous area may be considered free of asbestos if all samples from that area are shown to contain less than 1 % of asbestos.

6.1.4 Handling Precautions (3)—Asbestos should only be handled by trained personnel. If asbestos must be disturbed, the area should be isolated and well-labeled to protect employees not involved with the removal or repair work. Protective clothing including disposable coveralls, gloves, goggles, and a respirator should be worn when handling asbestos, and personnel should remove contaminated clothes and wash before leaving the work site. Material should be kept wet to minimize potential for airborne fibers. Waste products should be stored in plastic bags in a sealed rigid container and protected from physical damage. Asbestos material, including asbestos waste, should be stored in an isolated, regulated, and well-marked area. Smoking, eating, drinking, chewing, or applying cosmetics should be avoided in areas in which asbestos exposure is likely. Practice E 849 provides additional details. Asbestos replacement materials also may pose environmental, safety, and health risks.

6.2 PCB-Contaminated Media:

6.2.1 Description—PCBs have many useful properties including high stability, low vapor pressure, low flammability, high heat capacity, and low electrical conductivity. They are suspected carcinogens, however, and have been associated with adverse health and reproductive effects. They also have a high potential for bioaccumulation in the food chain. A number of trade names exist for PCBs, including Aroclor, Asbestol, Chlorextol, Diaclor, and Dykanol (4).

6.2.2 Uses—Because of the many positive characteristics of PCBs, oils containing PCBs have been used in a great variety of applications. The most common use has been as a dielectric fluid in transformers, capacitors, and other electrical equipment. The oil also has been used in many other situations
including hydraulic equipment, paints, oil-soaked gasket material, and as a plasticizer in many other products. PCBs have been banned in the United States since the mid-1970s, but materials manufactured after the ban have been found to contain them. Applications involving mobile forms of PCBs pose a much greater risk to personnel and the environment. Typical shipboard materials that may contain mobile forms of PCBs include electrical equipment containing dielectric fluid, oil-soaked gasket material, oil-soaked insulation material, and hydraulic fluids.

6.2.3 Test Methods:

6.2.3.1 Sampling—Because of significant variation in the PCB content of similar materials, mixing or combining samples prior to analysis is not recommended. Similarly, random samples cannot prove untested items either to contain or to be free of PCBs. Liquid oils may be sampled using Practices D 923.

6.2.3.2 Analysis—Materials may be analyzed using EPA SW-846, Method 8080.

6.2.4 Handling Precautions—PCBs should only be handled by trained personnel. Protective equipment should be worn when handling PCBs, with particular attention to avoiding skin and respiratory exposure. Work spaces should be well ventilated.

6.3 Refrigerants:

6.3.1 Description—Refrigerants present similar health and environmental dangers and may be discussed as a group. Many refrigerants are ozone-depleting substances. In general, refrigerants are relatively safe and stable gases, but may displace oxygen to dangerously low levels when released into confined spaces. Some refrigerants also may have acute toxic effects or result in increased cardiac sensitization at high concentrations.

6.3.2 Uses—A number of chemicals are used as refrigerants in shipboard air conditioning or refrigeration systems. Almost all are halocarbons, with CFC 12 and HCFC 22 being the most common of the traditional refrigerants. Concern for the ozone-depleting potential of these substances has led to the introduction of another common refrigerant, HFC 134a.

6.3.3 Test Methods—Identification of materials typically will not require testing. A quick review of system technical manuals should reveal the refrigerant used in the system, and any bottles containing refrigerant gas should be labeled.

6.3.4 Handling Precautions—Work on air conditioning and refrigeration systems should be performed only by qualified personnel. Refrigerants should not be intentionally released to the atmosphere. Refrigerants present in air conditioning or refrigeration equipment should be recovered and recycled (refrigerants typically have a high resale or recycling value), as described in ASHRAE Guideline 3. If accidental release occurs, personnel should leave the area and avoid inhaling vapors. Personnel requiring emergency medical attention following inhalation of refrigerants should not be given catecholamine drugs, such as epinephrine, because of the potential for increased cardiac sensitization. As a result of possible toxic by-products of combustion, refrigerants should be kept away from open flame. Smoking should not be allowed in areas in which refrigerants may leak to the atmosphere.

6.4 Used or Waste Oils:

6.4.1 Description—Waste oils include a variety of oil products that have been contaminated through use or storage to the point at which they can no longer be used for their intended purpose. Many used oils can be recycled. This category does not include water contaminated with small amounts of oil, which is addressed in 6.7.

6.4.2 Uses—The primary sources of shipboard used or waste oils are from hydraulic systems, engine room machinery, lubricating systems, and fuel systems.

6.4.3 Test Methods—Tests for halogen content and flash point are the most common, but test procedures will vary depending on the intended disposal method and suspected contaminants.

6.4.4 Handling Precautions—Recycling may include processes, such as reclamation, burning for energy recovery, reprocessing, or re-refining. The recycling potential of a used oil product will be dependent on the quantity of contaminants present. Contaminants may include arsenic, cadmium, chromium, lead, PCBs, sulfur, hydrogen sulfide, or halogens (chlorine, fluorine, and bromine). Unusually low flash points also may limit recycling potential, as will the presence of dispersants or emulsifying agents. Table 1 summarizes potential recycling problems associated with a variety of common oil products.

6.5 Paint Products:

6.5.1 Description—Paint often contains toxic constituents. Intact paint typically poses little risk, but exposure to toxic materials may occur during spraying, sanding, grinding, burning, or abrasive blasting procedures with paints containing even trace amounts of toxic chemicals. Potential toxic constituents in paint include fluoride salts and compounds of heavy metals. Toxic organic compounds such as benzene and toluene may be present in paint solvents. Toxic constituents are a concern because of the need to protect those applying or disturbing paint and because of disposal concerns associated with paint chips and contaminated blast grit. Paint found on older ships is of particular concern, as many layers of paint may be found in a single location.

6.5.2 Uses—Not applicable.

6.5.3 Test Methods—Old paint, applied to surfaces, may require analysis to determine toxic content before disturbing it.

6.5.3.1 Sampling—Care should be taken to ensure that samples are representative of the material being sampled. A representative sample should include all layers of paint.

6.5.3.2 Analysis (5)—While laboratory methods can determine the total quantity of toxic constituents in the paint, the capacity for the toxic constituents to leach out into the

| TABLE 1 Potential Recycling Problems Associated with a Variety of Common Oil Products |
|---------------------------------|---------------------------------|
| Product                         | Potential Problems              |
| Aviation fuels                  | low flash point, fire hazard     |
| Refrigeration lubricants        | halogenated hydrocarbon detergents/emulsifiers will not dissolve hazardous contaminants incompatible with petroleum products |
| Tank slops (from tank cleaning) |                                  |
| Grease (from trap cleaning), sludges |                          |
| Oily wastes: waste oil sludge, waste fuel oil, waste lubricant |                      |
| Synthetic oil                   |                                  |

surrounding environment may be determined using the Toxicity Characteristic Leachate Procedure, EPA SW-846, Method 1311.

6.5.4 Handling Precautions—Virtually all paint products contain some toxic constituents. Even small amounts of toxic materials present in paint coatings can result in some airborne exposure during spraying, sanding, grinding, burning, or abrasive blasting procedures, so protective equipment, including respirators and disposable clothing, should be used consistently to minimize risk to personnel, and work areas should be cleaned and well ventilated to remove any contaminated dust or debris (6). Dust, debris, and other waste materials with a high leachable toxic content may pose a long-term disposal problem as a result of potential contamination of landfills and groundwater near the disposal site.

6.6 Cleaning Products:

6.6.1 Description—Many cleaning products contain toxic chemicals. In some cases, large doses of these chemicals would be required for any adverse effect to human health, but some exposure paths require only small quantities of a chemical. Also, some cleaning products may interfere with the effectiveness of shipboard oily water separators. Also, sewage treatment plants using microbes to break down waste products can be damaged by the use of even small quantities of toxic materials.

6.6.2 Uses—Household cleaners, industrial solvents, and other cleaning products are found throughout most ships.

6.6.3 Test Methods—In most cases, cleaning products will be labeled clearly, making analysis unnecessary.

6.6.4 Handling Precautions—Specific handling and disposal instructions should be available through the manufacturer. Check for technical information, such as an MSDS.

6.7 Oily Water:

6.7.1 Description—Oily water is comprised primarily of oil and water, typically less than 5 % oil, but may contain other contaminants.

6.7.2 Uses—Sources for shipboard oily water include tank cleaning wastes, dirty ballast water, and water collecting in bilge spaces.

6.7.3 Test Methods—In some locations, tests are performed to determine the disposal requirements for oily water. If the oily water is suspected of containing solvents or other contaminants, the following tests are typically performed (others may be required): flash point, lead, zinc, tin, mercury, and carcinogenic materials.

6.7.4 Handling Precautions—The separation of a pure oil/water mixture is a relatively simple process, resulting in water of a high enough quality to be reintroduced into the environment in some locations and oil of a high enough quality to be burned for energy recovery. The presence of lead, mercury, or other toxic contaminants in the mixture may restrict disposal options, and the presence of emulsifying agents or detergents in the mixture may impair the separation process.

6.8 Soiled Rags:

6.8.1 Description—Rags used to clean any surface contaminated with oils, greases, solvents, or paints. Soiled rags are most often generated in machinery rooms, but also may be generated during maintenance on deck gear or in habitability areas.

6.8.2 Uses—Not applicable.

6.8.3 Test Methods—Not applicable.

6.8.4 Handling Precautions—Soiled rags should be bundled and carefully stored for disposal ashore. Rags soaked with oils, solvents, or paints may be highly flammable and have been known to combust spontaneously. Soiled rags should be stored in sealed containers in well-ventilated spaces and kept away from flame and high temperatures to minimize risk of fire.

6.9 Chemically Treated Water:

6.9.1 Description—Chemicals are often added to alter the water quality. These may include deoxidizing agents, such as hydrazine or sodium sulfate, added to minimize corrosion. Water also is treated with chemicals, such as lime, to reduce water hardness and prevent fouling. Ethylene glycol often is added to prevent water from freezing.

6.9.2 Uses—Most chemically treated water is found in boilers, condensers, and jacket water-cooling systems. Semi-permanent ballast water may also contain chemical additives.

6.9.3 Test Methods—Inspection of maintenance records should reveal chemical treatments used on the ship, eliminating the need for testing under most circumstances.

6.9.4 Handling Precautions—Options for discharge or disposal of chemically treated water may be restricted based on local discharge regulations or agreements. A high concentration of dissolved chemicals in the water may limit disposal options, as municipal water systems, which often eventually receive chemically treated water, typically prohibit certain contaminants. Table 2 and Table 3 provide additional information on common contaminants and their effect on water systems.

6.10 Firefighting Agents:

6.10.1 Description—Firefighting agents can be one of two general types. Streaming agents typically are handheld units used to direct the material at a fire source and usually are found in small canisters located throughout the ship. Flooding agents are typically installed systems designed to provide a large quantity of material throughout an area in which a fire is occurring and usually are found in large quantities in a central location with piping systems carrying the agent to distribution points.

6.10.2 Uses—Water, Halons, foaming agents, powders, and carbon dioxide are common firefighting agents.

TABLE 3 Common Prohibited Inputs to Sewage Systems

| Gasoline, fuel oil, and other flammable or explosive materials |
| Toxics, noxious, or poisonous materials |
| Ashes, cinders, sand, mud, glass, paper, rags, string, metals, plastics, feathers, or other materials likely to obstruct flow |

6.10.3 Test Methods—In most cases, firefighting agents will be labeled clearly making analysis unnecessary.

6.10.4 Handling Precautions—Cylinders of compressed gas should be handled gently, particularly if age or contents are unknown. Halons are ozone-depleting substances and should not be released to the atmosphere except in firefighting situations. Many firefighting agents are toxic, and direct contact with skin or through inhalation should be avoided. Specific handling and disposal instructions should be available through the manufacturer or distributor of the agent.

6.11 Unknown Material:

6.11.1 Description—Unlabeled containers of potentially hazardous material may be found. Identification of such containers through chemical analysis is costly, but necessary to ensure safe handling and disposal.

6.11.2 Uses—Not applicable.

6.11.3 Test Methods—The Toxicity Characteristic Leachate Procedure, EPA SW-846, Methods 1311 with the Method 8270 (Semi-Volatiles List) and Method 8260 (Volatiles List) may be used to identify hazardous constituents. Laboratory analysis should provide tentatively identified compounds (TIC) for any hazardous constituents identified. In some instances, tests for various heavy metals also may be appropriate.

6.11.4 Handling Precautions—Unknown material should be handled with extreme care and only by trained personnel wearing appropriate personal protective equipment. Contents of unlabeled containers should never be mixed. Smoking, eating, or drinking in the vicinity of unknown, but potentially hazardous, material should be avoided. Disposal alternatives will vary depending on the result of chemical analysis.

7. Documentation

7.1 Audit Report:

7.1.1 Summary—A summary section briefly describing the audit objectives and any notable conclusions that have been drawn from the audit.

7.1.2 Auditing Personnel—A complete list of auditing personnel, their accreditation and their affiliation to the vessel being audited.

7.1.3 Objectives—A description of the specific objectives and goals for the audit.

7.1.4 Target Shipboard-Generated Wastes—A list of target materials that will be included in the audit.

7.1.5 Test Methods—A specific description or reference to test methods used to identify the presence of target materials.

7.1.6 Results—A summary of the test results arranged in a clear and concise format.

7.1.7 Conclusions—A summary of target materials identified, handling and disposal options available, and a description of unanswered questions or concerns arising from the audit.

7.1.8 Appendices—May contain laboratory reports or other information supplementing the report described previously.

7.2 Record Retention—Audit reports and other supporting information should be retained in a central file as technical documentation for the ship. Supporting documents may be retained with audit reports to streamline the planning process for future audits.

8. Keywords

8.1 audit; hazardous material; hazardous waste; shipboard-generated wastes; ships; waste

Standard Guide for
Weight Control Technical Requirements for Surface Ships

1 This guide is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.07 on General Requirements.

1 Annual Book of ASTM Standards, Vol 01.07.
3.1.10 vertical center of gravity (KG or VCG), n—the point through which the gravitational forces on a ship pass measured vertically from the keel (K) or the ship’s baseline.

3.1.11 weigh; to weigh, v—as commonly understood in everyday usage and in the maritime industry, and as used throughout this guide, means to determine by measuring the mass of.

3.1.12 weight, n—as commonly understood in everyday usage and in the maritime industry, and as used throughout this guide, is synonymous with mass. In this guide, weight in inch-pound units is measured in pounds and in long tons of 2240 lbs; and in SI units (metric), weight is measured in kilograms and in metric tons of 100 kg. Refer to Practice F 1332 for conversion factors to convert inch-pound quantities to SI (metric) quantities for units of weight, moment, moments to trim, and so forth.

3.1.13 weight classification, n—the system used in light ship weight estimating for grouping materials, equipment, or components of the ship in a structured order to facilitate comparison and to ensure completeness.

3.1.14 weight group, n—one of the three major elements of light ship weight as used in the weight classification, that is, hull structure, outfit, and machinery.

4. Summary of Guide

4.1 Determination of Weight and Moment Data—The weight and moment data for all components and material and their overall effect on the ship’s weight, center of gravity, list, and trim should be determined. As ship design or ship construction drawings are prepared and as material is selected, acquired, or received, the weight and centers of gravity of all items that comprise the ship should be determined and reported in the weight estimates and reports. These data may be obtained by estimation or calculation during preliminary and contract design, by a combination of estimation or calculation of ship construction drawings, and by actual weight determination of items during detail design and construction.

4.2 Weight Reporting and Control—The procedures for weight reporting and control, regardless of the level of reporting, are described in Section 6 and apply for commercial ships. The method and frequency of weight reporting can vary depending on the specific ship design, as well as the technical requirements set forth in the contract. The extent and level of weight control also can vary depending on the specific ship design. Although the weight control technical requirements for commercial ships usually are less demanding than those for U.S. Navy surface ships, the need for a mechanism to control the weight of a ship still exists. Sections S1 – S4 describe the specific weight control technical requirements for U.S. Navy surface ships.

5. Significance and Use

5.1 It is important to know the amount of weight and its location before the ship is built to be sure that when it is built it will have positive stability. Only through detailed weight estimating in the design stage and during construction can one be ensured that positive stability will be achieved and retained.

6. Procedure

6.1 A specified number of calendar days, that is, 30, 45, 60, or 90 after date of award, as specified by the owner, the shipbuilder should submit for agreement an independent weight and center of gravity estimate. This estimate should describe the weight and centers of gravity of the ship in comprehensive detail and should include summaries and work sheets showing the detailed work performed, for example, calculations and estimates based on the design information, drawings, specification, and so forth. Appendix X1 contains suggested forms for the independent estimate, and it includes a suggested weight classification system for the estimate. Terms used in the weight classification are defined in the Maritime Administration Publication, Classification of Merchant Ship Weights.3

6.2 A mutual agreement between the shipbuilder and the owner on the light ship weight and centers of gravity should be reached as quickly as possible after award of the shipbuilding contract. Agreement action should consist of a review of shipbuilder’s independent weight and center of gravity estimates and comparison with the owner’s estimate. Upon resolution of differences, an agreed upon weight and center of gravity estimate will result. Thereafter, the shipbuilder should be responsible for obtaining in the completed vessel the agreed upon weight and center of gravity characteristics adjusted for authorized departures from the contracted ship design, reflected in the agreed upon estimate.

6.3 Departures from the contracted ship design, reflected in the agreed upon estimate, which affect the light ship weight and centers of gravity, should not be undertaken until the shipbuilder has submitted to the owner his estimate of the effect on weight and centers of gravity of the ship and obtained written approval to proceed with the department. Departures, which have a total impact on any weight group of less than a specified percentage, that is, 0.01, 0.02, 0.03, or 0.04 % of the light ship weight, may be considered negligible and will not require written approval with respect to weight.

6.4 The shipbuilder should submit periodically, as agreed upon, to the owner, a tabulation of approved departures and their cumulative effect on weight and centers of gravity of the agreed light ship estimate. In addition, when submitting plans that involve departures from the type of construction in the contracted ship design, reflected in the estimate, the shipbuilder should itemize such departures and their effect on light ship weight and centers of gravity in his periodic reports. A final report should be submitted at the time of delivery adjusted to bring the estimated light ship weight and centers of gravity into reasonable agreement with the inclining experiment results.

7. Keywords

7.1 light ship; ship acquisition; weight control; weight estimate; weight report

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified by the purchaser in the contract or purchase order. These requirements normally are invoked for U.S. Navy Surface Ships.

S1. SPECIAL GOVERNMENT REQUIREMENTS

S1.1 Government Documents, Drawings, and Publications—The following government documents, drawings, and publications form a part of this guide to the extent specified herein. Unless otherwise specified, the issues are those cited in the solicitation.

S1.1.1 Naval Sea Systems Command (NAVSEA) Documents:
- 0900-LP-039-9020 Ship Work Breakdown Structure for Nuclear Propulsion Plant (U)\(^4\)
- S9040-AA-IDX-010/SWBS 5D, Expanded Ship Work Breakdown Structure, Vol I\(^5\)
- S9040-AA-IDX-020/SWBS 5D, Expanded Ship Work Breakdown Structure, Vol II\(^5\)

S1.2 Nongovernment Publications—The following document(s) form a part of this guide to the extent specified herein. Unless otherwise specified, the issues of the documents, which are DOD adopted, are those listed in the issue of the Department of Defense Index of Specifications and Standards (DODISS) cited in the solicitation. Unless otherwise specified, the issues of documents not listed in the DODISS are the issues of the documents cited in the solicitation (see S4.1).

S1.2.1 ANSI Document:\(^6\)
- X3.4 Code for Information Interchange

Note S1—Nongovernment standards and other publications normally are available from the organizations that prepare or distribute the documents. These documents also may be available in or through libraries or other informational services.

S1.3 Order of Precedence—In the event of a conflict between the text of this guide and the references cited herein, the text of this guide takes precedence. Nothing in this guide, however, supersedes applicable laws and regulations unless a specific exemption has been obtained.

S2. TERMINOLOGY

S2.1 accepted ship report (ASR), \(n\)—the ASR is the document that demonstrates the contractor’s performance with regard to weight control. The ASR highlights the differences between the accepted weight estimate (AWE) or the allocated baseline weight estimate (ABWE) and the delivered ship as inclined.

S2.2 accepted weight estimate (AWE), \(n\)—the AWE defines the weight and centers of gravity of a ship that was awarded under a specification-type contract using the information that was available at the time of contract award. It establishes contractual values for weight and KG and is the baseline for detail design and construction.

S2.3 acquisition margins, \(n\)—acquisition margins are weight and KG allowances included in the weight estimate to cover the inherent limits of precision and the undefined variations of component weight and centers of gravity that take place throughout the design phases and during the construction of a ship. To provide for adequate weight control and configuration control, acquisition margins are divided into five accounts: preliminary design margin, contract design margin, detail design and building margin, contract modification margin, and government-furnished material (GFM) margin.

S2.4 actual weight, \(n\)—actual weight is the value obtained by a measurement of material on an accurate scale or other weighing device.

S2.5 allocated baseline weight estimate (ABWE), \(n\)—the ABWE is the contractor’s definition of the weight and centers of gravity of a ship that was awarded under a performance-type contract at the time of hull and propulsion configuration approval. It is the baseline for detail design and construction.

S2.6 baseline weight estimate (BWE), \(n\)—the BWE is any designated weight estimate that is used as a starting point in a design phase for comparative analysis with subsequent weight estimates. Before contract award, the final estimate of each design phase is usually the baseline estimate for the succeeding phase. After contract award, the AWE or ABWE usually is the baseline estimate for the remainder of detail design and construction.

S2.7 bidder’s independent weight estimate (BIWE), \(n\)—the bidder’s (or offeror’s) independent weight estimate is prepared by each potential contractor in response to a solicitation. It is the bidder’s evaluation of the ship design based on the ship specifications, drawings, and data that comprise the contract package.

S2.8 calculated weight, \(n\)—calculated weight is weight computed from ship construction drawings and vendor drawings.

S2.9 capacity load condition (Condition E), \(n\)—the capacity load condition is the ship complete and ready for service in every respect. It is light ship (Condition A) plus the following variable loads: maximum number of officers, crew, and passengers that can be accommodated and their effects; maximum stowage of ammunition in magazines and ready service spaces; full allowance of aircraft and vehicles (fully fueled with full allowance of repair parts and stores); maximum amount of provisions and stores that can be carried in the assigned spaces; and maximum capacity of liquids in tanks. Fuel and lube oil shall be not greater than 95% of tank capacity, unless such tanks are compensating. Compensating tanks shall be considered filled with 95% fuel and 5% salt water. Maximum amounts of cargo and supplies, other than for ship’s own use,

\(^4\) Available from the Navy Ships Parts Control Center (SPCC), Code 709 Mechanicsburg, PA 17055.
\(^5\) Available from Naval Sea Logistics Center, Code 623, PO Box 2060, Mechanicsburg, PA 17055-0795.
\(^6\) Available from American National Standards Institute (ANSI), 25 W. 43rd St., 4th Floor, New York, NY 10036.
shall be included to the full capacity of the assigned spaces. This load condition shall be not greater than the limiting drafts.

S2.10 category, n—category is a fundamental unit of machinery weight classification for nuclear-propelled ships in accordance with NAVSEA 0900-LP-039-9020.

S2.11 category system, n—category system is a system of machinery weight classification for nuclear-propelled ships in accordance with NAVSEA 0900-LP-039-9020.

S2.12 contract data requirements list (CDRL) (DD Form 1423), n—a CDRL is a contract form listing all data items selected from an authorized data list to be delivered under the contract. It includes the format, content, frequency, submittal, and distribution requirements.

S2.13 contract design margin, n—the contract design margin is a weight and KG allowance included in the weight estimate to account for increases associated with design development during the contract design phase. This margin is included in the feasibility and preliminary design phases. No portion of this margin is consumed before the start of contract design.

S2.14 contract design weight estimates (CDWE), n—the CDWE is the weight estimate of the light ship, full load, and any other specified loading condition prepared during the contract design phase.

S2.15 contract modification margin, n—the contract modification margin is a weight and KG allowance included in the weight estimates and reports to account for increases associated with contract modifications issued during the detail design and construction phase. This margin is included in the feasibility, preliminary, and contract design phases. For performance-type contracts, this margin is also included in detail design and building phase. No portion of this margin is consumed before award of the detail design and construction contract.

S2.16 contract modification summary, n—the contract modification summary is a complete listing of the weight and moment effects of approved contract changes. This information is included as an appendix to the quarterly weight reports, the accepted ship report, and the final weight report.

S2.17 contractor-responsible condition, n—the contractor-responsible condition is the full-load condition without the effects of contract modifications, changes in GFM, and other allowable changes after the establishment of the AWE or ABWE. This condition is used to measure the contractor’s progress in achieving his requirement to deliver the ship within contractual values (see S3.3.4.6).

S2.18 current weight, n—current weight consists of the most accurate data available on the date of a given weight estimate or report. The summary of current weight is frequently a combination of estimated, calculated, and actual values.

S2.19 design and weight data sheet, n—the design and weight data sheet is a one-page summary that includes group level weight data, hull characteristics data, displacement, and stability characteristics data, load data, and machinery data.

S2.20 detail design and building margin, n—detail design and building margin is a weight and KG allowance included in the weight estimates and reports to account for design changes as a result of ship construction drawing development; growth of contractor-furnished material; omissions and errors in the AWE or ABWE, as well as differing shipbuilding practices, omissions and errors in the ship construction drawings; unknown mill tolerances; outfitting details; variations between the actual ship and its curves of form; and similar differences. This margin is to compensate for all contractor-responsible differences between the AWE or ABWE and the results of the inclining experiment, as well as tolerances for experimental variation in the inclining experiment. This weight and KG allowance is budgeted and included in the feasibility, preliminary, and contract design phases, but no portion of this margin is to be consumed before award of the detail design and construction contract. Values for these margins are to be selected by the offeror and included along with rationale for their basis in BIWEs or PABWEs. The final margin allowances are then subject to negotiation between the government and the contractor that was selected for detail design and construction.

The design and building weight margin shall be located at the same center of gravity as the summation of weight groups one through seven.

S2.21 electronic media, n—electronic media is used to transfer detailed weight and moment data that complies with the Navy standard weight estimate format and is used by NAVSEA to prepare Navy weight estimates and reports (see Annex A1).

S2.22 estimated weight, n—estimated weight is based on preliminary data and is subject to revision when more accurate information is available, such as when more detailed drawings are developed or when components are actually weighed.

S2.23 expanded ship work breakdown structure (ESWBS), n—ESWBS is a five-digit functional classification system in accordance with NAVSEA S9040-AA-IDX-010/SWBS 5D and S9040-AA-IDX-020/SWBS 5D (Vol I and II). For weight reporting purposes, only the first three digits of this system apply. The fourth and fifth single digit classification levels are used to incorporate the functions that support maintenance and repair needs.

S2.24 feasibility study weight estimate, n—the feasibility study weight estimate is a compilation of the ship’s weight and center of gravity data that result in light ship, full load, and any other specified loading conditions. This estimate is prepared during the feasibility study design phase.

S2.25 final weight report (FWR), n—a FWR is a detailed final report of weight and moment data for all required loading conditions. This report accurately reflects accumulated values for estimated, calculated, and actual weight data for the detail design, including the net effect of changes to GFM and adjudicated and unadjudicated contract modifications.

S2.26 full load condition (Condition D), n—the full-load condition is the ship complete and ready for service in every respect. It is light ship (Condition A), plus the following variable loads: authorized complement of officers, crew, and passengers and their effects; full allowances of ammunition in magazines and ready service spaces; full allowance of aircraft and vehicles (fully fueled with full allowance of repair parts and stores); full supply of provisions and stores for the periods specified in the design characteristics; full potable water tanks;
lube oil tanks to 95% of capacity; fuel tanks to 95% capacity, or in the case of compensating tanks, 95% fuel and 5% salt water; sewage collecting, holding, and transfer tanks to 25% capacity; anti-roll tanks to operating levels; and all other liquids in tanks to required capacity in accordance with characteristics and liquid-loading instructions. The ammunition, stores, fuel, and other liquids referred to previously are for the ship’s own use. Cargo (liquid and solid) is included in the amounts normally carried or to the specified portion of the full capacity of the assigned spaces.

S2.27 government-furnished material (GFM) margin, n—the GFM margin is a weight and KG allowance included in the weight estimates and reports to account for increases caused by the growth in GFM during the detail design and construction phase. This margin is included in the feasibility, preliminary, and contract design phases. For performance-type contracts, this margin is also included in detail design and building phase. No portion of this margin is consumed before award of the detail design and construction contract.

S2.28 government-furnished material summary, n—the GFM summary is a complete listing of weight and center of gravity data for material and equipment that will be provided by the government. The baseline GFM summary, which is included as part of the AWE or ABWE, reflects the Schedule A portion of the contract at the time of contract award. The GFM summary is continuously updated as the detail design weight estimates mature and the Schedule A is modified. Also, where the contract permits, the GFM summary can include other government-responsible equipment, such as equipment designated as standard for the class, directed procurement, and so forth.

S2.29 group, n—group is a fundamental unit of ship classification, identified by one numeric digit or an alphabetic designator. For weight estimates and reports, a group is the first character of the three-digit system. The summation of weights and moments for all of the three-digit elements that begin with the number one is the total for Group one, and similarly for the other groups.

S2.30 gyrodus, n—the gyrodus for roll, pitch, or yaw is the square root of the quotient of the ship’s weight moment of inertia about the roll, pitch, and yaw axes, respectively, divided by the ship’s displacement.

S2.31 inch-pound units, n—inch-pound units comprise a system of units using pounds, long tons, ft, ft-lbs, and ft-tons for reporting mass properties data. These weight and moment data are carried to the nearest pound and ft-lb at all detail levels. In addition, summaries are converted and reported to the nearest one-hundredth of a long ton and to the nearest ft-ton. All levers are carried to the nearest one-hundredth of a foot.

S2.32 KG, n—KG is defined as the height of the ship’s vertical center of gravity as measured from the bottom of the keel (includes keel thickness). When using SI units, care must be taken not to confuse the naval architectural symbol KG, in uppercase letters, with the SI symbol, kg, in lowercase letters (which represents the SI unit kilogram).

S2.33 light ship condition (Condition A), n—the light ship condition is the ship complete, ready for service in every respect, including permanent solid and liquid ballast, onboard repair parts, and liquids in machinery at operating levels, without any items of variable load.

S2.34 longitudinal lever, n—the longitudinal lever is the perpendicular distance from a transverse plane through the ship’s longitudinal reference to the center of gravity of an item. The longitudinal reference is located at the forward perpendicular, unless otherwise specified by the design contract or Ship Specification Section 096.

S2.35 mass properties data, n—mass properties data are those physical characteristics that define the magnitude, location, and distribution of weight in the ship. They include weight, centers of gravity location, moments, and weight moments of inertia.

S2.36 metric units, n—metric units comprise a system of basic measures that are defined by the International System of Units based on “Le Systeme International d’Unites (SI)” of the International Bureau of Weights and Measures.

S2.37 moment, n—a moment is the product of a weight and its lever. For example, the longitudinal moment of an item is the product of the weight of the item multiplied by its longitudinal lever.

S2.38 percent completion, n—percent completion is the ratio of the current weight, less the current estimated weight, to the current weight, expressed as a percentage.

S2.39 performance-type contract, n—a performance-type contract is the vehicle for ship acquisition resulting from a description of operational and mission requirements. Since the shipbuilder usually has substantial latitude in determining ship size and configuration, a PABWE or ABWE is used in this situation.

S2.40 pitch moment of inertia, n—moment of inertia about the transverse axis through the ship’s center of gravity.

S2.41 preliminary allocated baseline weight estimate (PABWE), n—the PABWE is the potential bidder’s (or offeror’s) estimate of the weight and center of gravity of the ship in response to a solicitation for a performance-type contract.

S2.42 preliminary design margin, n—preliminary design margin is a weight and KG allowance included in the weight estimates to account for increases associated with design development during the preliminary design phase. This margin is included in the feasibility design phase. No portion of this margin is consumed before the start of preliminary design.

S2.43 preliminary design weight estimate, n—preliminary design weight estimate is the weight estimate of the light ship, full load, and any other specified load condition prepared during the preliminary design phase.

S2.44 quarterly weight report (QWR), n—a QWR is a periodic assessment of displacement, drafts, trim, list, GM, and KG as the weight estimate matures during detail design and construction.

S2.45 roll moment of inertia, n—moment of inertia about the longitudinal axis through the ship’s center of gravity.

S2.46 service life allowances, n—service life allowances are weight and KG budgets included in the design to accommodate changes as a result of both authorized (for example, ship alterations) and unplanned growth (for example, paint,
personal belongings, and so forth) during the ship’s operational lifetime, which tends to increase displacement and impact stability.

S2.47 SI units (International System of Units), n—SI units (see Practice F 1332) comprise a system of units using kilograms (kg), metric tons, metres (m), kg/m, and metric ton-m for reporting mass properties data. All levers are carried to the nearest one-hundredth of a m. The weight and moment data are carried to the nearest kg and kg/m at all detail levels. In addition, summaries are converted and reported to the nearest one-hundredth of a metric ton and to the nearest metric ton-m.

S2.48 specification-type contract, n—a specification-type contract is the vehicle for ship acquisition resulting from a Navy controlled contract design. The products of the contract design, which usually become part of the shipbuilding contract and therefore the basis for the BIWE, include items such as: midship section drawing, lines drawing, table of offsets, general arrangement drawings, the shipbuilding specifications, and special requirements like not-to-exceed weight and KG values.

S2.49 standard longitudinal station breakdown, n—the standard longitudinal station breakdown is a system consisting of 22 stations designated by the letters A through X (excluding I and O). Station A is the only station forward of the forward perpendicular (FP). Station X is the only station aft of the aft perpendicular (AP). Stations B through W extend from the FP to the AP, and each comprises 1/20 of the length between perpendiculars.

S2.50 three-digit system, n—The three-digit system is a means of classifying mass properties data in a structured order. Every item that comprises the completed ship is included in the weight estimates and reports grouped in accordance with the three-digit system. Unless otherwise specified, the three-digit system for weight estimates and reports is the same as the first three digits of the ESWBS. An example of this numerical ordering is shown in Fig. S2.1.

S2.51 transverse lever, n—transverse lever is the perpendicular distance from the vertical centerline plane of the ship to the center of gravity of an item.

S2.52 vertical lever, n—vertical lever is the perpendicular distance from a horizontal plane through the molded baseline of the ship to the center of gravity of an item.

S2.53 weight control, n—weight control is all of the necessary actions, such as predicting, estimating, calculating, weighing, reporting, analyzing, evaluating, and reversing adverse trends to ensure that a ship’s weight and moments are consistent with its naval architectural limits for displacement, strength, stability, list, trim, and performance, such as speed, endurance, and seakeeping.
S2.54 weight control plan, n—a weight control plan outlines the procedures that will be followed to meet contractual weight control responsibilities (see S3.3.3.5).

S2.55 weight distribution, n—a weight distribution is a weight summary by the standard longitudinal station breakdown and is used to develop shear forces and bending moments.

S2.56 weight moment of inertia, n—weight moment of inertia about any reference axis through the ship’s center of gravity is the summation of the moment of inertia of each item about its own axis (parallel to the reference inertia axis), plus the products obtained by multiplying the weight of each item by the square of its distance from the reference inertia axis (see S3.3.2.3).

S2.57 weight reporting, n—weight reporting is the preparation and submission of the most accurate and current weight and moment data available at designated intervals throughout the design and construction phases.

S2.58 yaw moment of inertia, n—moment of inertia about the vertical axis through the ship’s center of gravity.

S3. PROCEDURES

S3.1 General Report Requirements—The contract will invoke this guide and specify technical data to be prepared, including modifications and exceptions. The CDRL will specify requirements for deliverables, such as data to be submitted, frequency of submission, number of copies, and recipients. The general requirements for the weight estimates and reports listed in this standard are specified in S3.1.1 through S3.2. The interface of weight estimates and reports is depicted in Fig. S3.1.

S3.1.1 Loading Conditions—Weight estimates and reports shall contain loading conditions for light ship, full load, and contractor responsibility, unless otherwise specified by the contract. The light ship condition includes a summary of one-digit groups and the remaining acquisition margin. These values are combined to result in the light ship weight, centers of gravity, and associated moments. The light ship condition in the FWR shall be adjusted to correlate with inclining experiment data. Building margin is used to account for irreconcilable differences between the FWR and the inclining experiment. Building margin is the only acquisition margin account that is permitted in the FWR. Other margin accounts, such as detail design margin, will either be fully depleted or if remainders exist they should be deleted from the FWR. The full-load condition is computed by adding specified items of variable load to the light ship condition and reflects the actual ship that is planned for delivery. The contractor-responsible condition is the full-load condition without the effect of contract modifications, both adjudicated and unadjudicated; the net weight change and associated moment changes from baseline values of current GFM items that were included in the original Schedule A or were subsequently added to Schedule A through a change in acquisition responsibility; and other
allowable changes beyond the control of the contractor (see S3.3.4.6). This condition is used to assess contractual performance. In addition to the total weight, centers of gravity, and associated moments, each loading condition also shall display KG, metacentric height (uncorrected and corrected for the free surface effect of liquids in tanks), list, trim, and drafts above the bottom of the keel at the perpendiculars and midship. Figs. S3.2-S3.4 provide examples of typical loading conditions.

S3.1.2 Margins—Acquisition margins shall be included in the estimates and reports. Throughout the design cycle, the appropriate margin account shall be adjusted concurrently to compensate for departures from the original estimates. This computation permits the maintenance of a constant design baseline until the budgeted margin account is exceeded. Weight margins shall be located at the same centers of gravity as the ESWBS current one-digit totals. Fig. S3.5 provides a typical example.

S3.1.3 Reasons for Changes—Weight estimates and reports shall include an addendum that explains each cause of significant change in weight or moment within every three-digit element. Unless otherwise specified, a significant change is a 1% or greater difference from an element’s previous estimate. A brief narrative of the ship’s condition relative to its naval architectural or contractual limits shall be included in this section. If any of these limits is in jeopardy, recommendations for reversing the adverse trend are also required.

S3.1.4 Table of Contents—The estimates and reports shall contain a table of contents.

S3.1.5 Special Coding—An explanatory note and remarks section shall be included to define special coding symbols, such as material codes, GFM indicators, and reasons for change indicators.

S3.1.6 Lever Symbol—Vertical levers shall be indicated by a “−” for below the baseline and a “+” or a blank for above the baseline. Longitudinal levers shall be indicated by an “F” or a “−” for forward of the reference plane and an “A,” a “+,” or a blank for aft of the reference plane. Transverse levers shall be indicated by a “P,” a “+,” or a blank for port and an “S” or a “−” for starboard.

S3.1.7 Reporting System Units—Estimates, reports, and other specified mass properties documentation and data shall be reported in either inch-pound or metric units as specified in the contract.

S3.1.8 Paper—Estimates and reports shall be machine written on 8 1/2- by 11-in. paper, and protected by hard covers, but not permanently bound. The original or reproducible copy shall be suitable for microfilming.

S3.1.9 Supporting Documents—Background information, studies, directives, correspondence, and all detail calculations pertaining to weight and moment data, including density factors, shall be made available to the Navy upon request.

*Note:* Inch-pound units are shown in example; however SI units are applicable when specified.
S3.2 Classified Reports—Weight reports containing classified data shall be marked in accordance with the security requirements contained in the contract. Whenever possible, classified or proprietary material shall be downgraded by deleting classified or proprietary portions that do not impair the usefulness of the document.

S3.3 Detailed Requirements:

S3.3.1 Predetail Design Phase—Estimates, reports, and supplemental documents for these design phases shall be prepared in accordance with S3.3.1.1 through S3.3.2.10, as applicable, unless otherwise specified.

S3.3.1.1 Weight Estimates and Reports—Weight estimates and reports prepared during these phases consist of baseline weight estimates, interim reports, and final design weight estimates. These estimates and reports contain detailed information appropriate to the design phase, loading conditions for light ship and full load, and are summarized in tabular form as follows:

(a) Three-digit system number and title.
(b) Current weight.
(c) Current vertical lever.
(d) Current vertical moment.
(e) Current longitudinal lever.
(f) Current longitudinal moment.
(g) Current transverse lever.
(h) Current transverse moment.

The mass properties data included in these estimates and reports are based on the engineering products available before the date of the document.

S3.3.1.2 Baseline Weight Estimates—The initial estimate for a given design phase is designated the baseline weight estimate. The baseline weight estimate consists of the light ship, full load, and any other specified loading condition. The estimate shall be titled Baseline Preliminary or Baseline Contract Design Weight Estimate. The requirements for the estimate are as specified in S3.3.1.1.

S3.3.1.3 Interim Reports—Weight estimates produced at specified intervals during a given design phase are designated interim weight reports. The interim report summarizes the current weight and moment status of the design and highlights any changes that occurred during the reporting period. The report shall contain the light ship, full load, and any other specified loading condition. It also shall reflect the appropriate title, such as Preliminary Design Interim Report No. 2. Fig. S3.6 and Fig. S3.7 provide typical examples. In addition to the requirements specified in S3.3.1.1, the report shall contain the following:

(a) Previous design phase group level summary.
(b) Previous report group level summary.
(c) Current group level estimate, and when required, the element level estimate and longitudinal weight distribution data.
(d) Net change, by group and total, between (a) and (c).

(e) Net change, by group and total, between (b) and (c).

(f) The current status of margins, loads, full-load displacement, KG, list, and trim. The changes corresponding to the total net change calculated for (d) and (e) shall be shown for margins, loads, and full-load displacement.

(g) A brief narrative providing rationale for any significant changes since the previous report and classified by the groups in which the changes occurred.

S3.3.1.4 Final Design Weight Estimate—The final estimate produced during a design phase is designated as the final design weight estimate. This estimate will reflect the final weight and moment data for light ship, full load, and any other specified loading condition. The estimate shall be titled Final Preliminary or Final Contract Design Weight Estimate. The requirements for the estimate are specified in S3.3.1.1 and S3.3.1.3.

S3.3.2 Supplemental Documents—The supplemental documents specified in S3.3.2.1 through S3.3.2.10 shall provide additional information and background data required during the preliminary/contract design phases.

S3.3.2.1 Weight and Moment Trade-Off Studies—These studies consist of determining the mass properties impact of various configuration change proposals and engineering alternatives that are being considered for inclusion in the design. The studies are delivered on an “as requested” basis and contain detailed mass properties calculations that define the impact of the study on ship displacement, KG, list, and trim. There is no fixed format for the completed study, but the ESWBS classification system shall be used to structure and summarize the data.

S3.3.2.2 Weight Distribution Report—A longitudinal weight distribution shall be provided in a tabulated format in accordance with the standard longitudinal station breakdown. Weight and longitudinal center of gravity shall be determined for each ship station for both light ship and full-load condition. The resultant total weight and longitudinal center of gravity for the weight distribution report for each condition shall equal the values reflected in the weight estimate or report for the same condition in that reporting period.

S3.3.2.3 Weight Moment of Inertia—When specifically required by the contract, weight moment of inertia data shall be included for the full-load condition. Current weights, centers of gravity, and engineering information describing the shape and orientation of each data element shall be used to develop weight moment of inertia data. The minimum data required are as follows:

(a) Ship-oriented roll, pitch, and yaw weight moments of inertia about each individual data element’s centroidal axes.

(b) Ship-oriented roll, pitch, and yaw weight moments of inertia about the ship’s centroid in the full-load condition.
S3.3.2.4 Ship Specification Sections—Ship specification sections shall define the requirements of the weight control program and the range of acceptable trim and list limit values that are to be invoked upon the shipbuilder. Deviations from this standard, such as special loading conditions, reporting units, or margins, shall be defined clearly. The format for the specification sections will be provided by NAVSEA.

S3.3.2.5 Circular of Requirements Sections—These sections shall provide the weight control requirements when a performance-type contract is used. The content of these sections shall be similar to S3.3.2.4, with the addition of service-life allowance quantities.

S3.3.2.6 Contract Data Requirements List (CDRL)—A CDRL will be developed that itemizes the data deliverables that shall be required by the ship acquisition contract. The portion of the CDRL that contains weight estimates, reports, and supplemental documents shall be generated during the contract design phase (see S4.2).

S3.3.2.7 Solicitation Input—A request for proposals or similar document shall be prepared that describes the ship design to potential shipbuilders and defines the format for submitting a bid or making an offer. The following portions of the solicitation package that pertain to weight control shall be generated during contract design:

(a) Instructions to Offerors—This section describes the content of the weight control material that will be submitted for source selection consideration. The bidder’s Independent Weight Estimate or Preliminary Allocated Baseline Weight Estimate, Preliminary Weight Control Plan, and resumes of weight control personnel are typical examples.

(b) Factors for Determining Loads—These are allowances, densities, and stowage factors that are used in the variable load portion of the full-load condition are included in the solicitation to permit a consistent calculation of load items by the bidders or offerors.

(c) Weights for Schedule A Items—This listing establishes the baseline GFM weight that will be required in the AWE/ABWE.

S3.3.2.8 Weight Control Contract Clause—The contract clause for weight control shall be provided for inclusion in the shipbuilding contract. The clause shall contain Not-To-Exceed (NTE) displacement and KG values, when applicable; a requirement for adjudicating the weight and moment effect of contract changes; a requirement that GFM growth is to be agreed upon before the inclining experiment; an explanation of the contractor-responsible condition; the method of incorporating changes that are proposed solely to achieve satisfactory naval architectural characteristics; and the amount of liquidated damages that apply.

S3.3.2.9 Design Notebook—The design notebook shall include a completed set of weight data collection sheets. For each system, these sheets describe the composition of the system,

**COMMENTS:**

Note: Inch-pound units are shown in example, however SI units are applicable when specified.
the source of the mass properties data, the latitudes in the system definition that could cause weight variations, the parameters and assumptions that were used to generate the mass properties data, and the concurrence of the cognizant technical code. In addition to the weight data collection sheets, the design notebook shall include a record of the information that was used in the development of the estimates and reports. This information typically consists of engineers’ notes, memora- nanda, records of telephone conversations, margin determination/rationale, interim reports, material equipment lists, and an index of drawings, sketches, and reports that were translated into mass properties data. Separate notebooks are required for preliminary design and contract design.

S3.3.2.10 Design History—The design history is a combination of narrative and tabular data that summarizes in chronological order the mass properties evolution of the ship design. The text highlights the major problem areas and their resolutions during the design phase, significant issues and decisions that had an impact on mass properties, and a discussion of margin usage. The narrative is interspersed with summary data from the weight estimates and reports. Separate histories are required for preliminary design and contract design.

S3.3.3 Pre-Award Process—This process is the period between the release of the request for proposals (RFP) or request for bids and the award of the contract. Estimates and supplemental documents required during this process shall be in accordance with S3.3.3.1 through S3.3.3.2, as applicable.

S3.3.3.1 Weight Estimates—The BIWE or the PABWE is prepared during this process. The estimate shall contain detailed information appropriate to the design phase and loading conditions for light ship and full load and shall be summarized in tabular form as follows:

(a) Three-digit system number and title.
(b) Current weight.
(c) Current vertical lever.
(d) Current vertical moment.
(e) Current longitudinal lever.
(f) Current longitudinal moment.
(g) Current transverse lever.
(h) Current transverse moment.

When a technical evaluation is conducted during source selection, the estimate is reviewed for appropriate content and scored against the requirements. After contract award, the successful bidder’s, or offeror’s, estimate becomes the basis for the AWE or ABWE.

S3.3.3.2 Bidder’s Independent Weight Estimate (BIWE)—The BIWE establishes the potential contractor’s estimate of the ship design before contract award. It is based on the contract, ship specifications, all of the documents referenced therein, the factors for determining loads, and the weights for GFM. The BIWE shall conform to the content and format requirements of S3.3.3.1, include estimated values for design and building margin, and contain loading conditions for light ship and full load. The variable loads shall be realistically distributed throughout the ship in their appropriate spaces. The bidder, or offer, shall include in appendices the following information:

(a) Historical backup data for estimating factors that were used in the development of the BIWE, such as mill tolerance, paint, weld material, insulation, and so forth.
(b) The technical analysis that substantiates the values selected for design and building margin.
(c) A summary of GFM as reported in the details of the BIWE (see S3.3.3.1).

When NTE displacement and KG values are defined in the contract, the bidder, or offeror, shall take the appropriate measures to reflect the design solutions and building practices that ensure delivery of a satisfactory ship.

S3.3.3.3 Preliminary Allocated Baseline Weight Estimate (PABWE)—The PABWE establishes the potential contractor’s estimate of the ship design before the award of a performance-type contract. It is based on the contract, Circular of Requirements, all the documents referenced therein, and the bidder’s, or offeror’s, proposed hull and propulsion configurations. The report shall conform to the requirements of S3.3.3.1, include estimated values for design and building margin, and contain contract modification and GFM margins as specified. Variable loads shall be realistically distributed throughout the ship in their appropriate spaces. The bidder, or offeror, shall include in appendices the following information:

(a) Historical backup data for estimating factors that were used in the development of the PABWE, such as mill tolerance, paint, weld material, insulation, and so forth.
(b) The technical analysis that substantiates the values proposed for design and building margin.
(c) A summary of GFM as reported in the details of the PABWE (see S3.3.4.3).

After contract award, the PABWE of the successful bidder, or offeror, becomes the basis for the ABWE, which is used to measure contractor responsibility.

S3.3.3.4 Supplemental Documents—The supplemental documents specified in S3.3.3.5 and S3.3.3.6 provide additional information and background data required during the pre-award process.

S3.3.3.5 Preliminary Weight Control Plan—A preliminary weight control plan shall be submitted with detail design and construction proposals that outlines the procedures that shall be followed to meet contractual weight control responsibilities. The plan shall include, but is not limited to, the following topics:

(a) A discussion of design risk with respect to the ship’s naval architectural characteristics, including special weight control problems and the areas that will receive weight control emphasis.
(b) A discussion of the method to be used in adjusting margin accounts.
(c) The frequency of briefings to top management concerning the ship’s naval architectural condition throughout the detail design and construction phase. The individual who will give the briefings shall be identified.
(d) A description of the computer systems, both hardware and software, that will be used in the weight control effort.
(e) A listing of equipment that will be used to perform actual weight measurements. The listing shall include equipment capacity, accuracy tolerance, and calibration frequency.
S3.3.4.1 Weight Estimates and Reports—Weight estimates and reports prepared during this phase consist of the ABWE or AWE, QWR, and FWR. These estimates and reports shall contain detailed information appropriate to the status of the design at the time of submittal and loading conditions as described in S3.1.1, and shall be summarized in tabular form as follows:

(a) Three-digit system number and title.
(b) Original weight (not required for AWE or ABWE).
(c) Current weight.
(d) Current vertical lever.
(e) Current vertical moment.
(f) Current longitudinal lever.

g) Current longitudinal moment.
(h) Current transverse lever.
i) Current transverse moment.
j) Current percent completion (not required for AWE or ABWE).
k) Special coding symbols.

S3.3.4.2 Every item that comprises the completed ship shall be included in the weight estimates and reports and grouped in accordance with the three-digit system. For the data to be useful in a variety of applications, the details shall contain an accurate description that links each listed item to a recognizable component. For example, a long listing of plates, tees, angles, beams, chocks, and so forth, with precise weight and center of gravity data, does not comprise a satisfactory estimate, unless those pieces of structure can be readily identified with a specific bulkhead, deck, foundation, or other structure. Similarly, the descriptions for distributive systems shall indicate the major components that are being connected. Component descriptions shall include identifiers, such as type, size, rating, capacity, and so forth. An example of adequate detail and proper numerical ordering is shown in Fig. S2.1. Calculations and actual weight determinations shall be terminated in advance of report preparation to ensure timely submittals.

S3.3.4.3 Determination of Mass Properties Data—Mass properties data may be obtained by a combination of estimation or calculation of ship construction drawings and actual weight determination. The actual weight of all components and equipment, greater than 500 lbs or 225 kg (unless otherwise specified), both contractor and government-furnished, shall be determined through accurate scale weighing along with the estimation or calculation of centers of gravity. The actual weights for materials, components, and equipment, less than 500 lbs or 225 kg, shall be determined on a selective or sampling basis, as determined by the contractor, to provide unit weight data. Potential candidates for actual weight determination on a selective basis include such items as insulation, structural plates and shapes, sheathing, piping, and the components and equipment less than 500 lbs or 225 kg. Where factors or percentages are used, such as for estimating and calculating paint, mill tolerance, and welding, the contractor shall substantiate these values by supplying background information (current and historical). Historical background information on paint, mill tolerance, and welding factors shall be forwarded with the BIWE or PABWE. Final values for paint, mill tolerance, and welding factors, based on current ship information, shall be forwarded with the FWR. Also, when design development has occurred for a component, system, or portion of structure, a reevaluation of the original weight estimate shall be made to obtain the most accurate current weight. In addition, to minimize the amount of actual weight determination at the shipbuilding site, the contractor shall require, through acquisition documents, subcontractors or vendors to submit information on the current weight and center of gravity of all major assemblies, equipment, fittings, or components to be installed on the ship. It is suggested that information be submitted by subcontractors or vendors in the following sequence:
(a) An estimate of weight and center of gravity in the proposal.
(b) The calculated weight and center of gravity when the design is completed.
(c) The actual weight and calculated center of gravity when the fabrication or assembly is completed.
S3.3.4.4 Accepted Weight Estimate (AWE)—After contract award, the contractor and NAVSEA shall agree on AWE values for displacement and KG. To expedite this agreement, the contractor shall, upon request, visit NAVSEA not less than one month before the required submittal date of the AWE. The estimate shall consist of the contractor’s BIWE that was submitted during the solicitation process, adjusted as necessary to reflect corrections and negotiated changes, such as reclassification of data. The AWE shall include loading conditions, summaries, supporting details for each three-digit element, appropriate margins, and an appendix that establishes the baseline for measuring detail design changes in GFM. The estimate shall conform to the content and format requirements of S3.3.4.1.
S3.3.4.5 Allocated Baseline Weight Estimate (ABWE)—The ABWE establishes the contractor’s estimate of the ship design when the hull and propulsion configurations are defined. The ABWE shall reflect a design that meets all of the required performance criteria, satisfies the required service-life allowances, and includes the appropriate margins. The basis for the estimate shall be the contractor’s PABWE that was submitted during the solicitation process, adjusted as necessary to reflect design changes and corrections. The ABWE shall include loading conditions, summaries, margins, and an appendix that establishes the baseline for measuring detail design changes in GFM. The estimate shall conform to the content and format requirements of S3.3.4.1.
S3.3.4.6 Quarterly Weight Reports (QWR)—The QWR shall document the current mass properties status of the ship design and construction effort. The light ship and full-load conditions shall reflect the ship that is projected for delivery, including the current mass properties values for GFM and contract modifications, both adjudicated and unadjudicated. The contractor-responsible condition shall be used to adjust the current full load to account for changes that occur after the establishment of the contractual baseline and are not within the control of the shipbuilder. Examples of these types of changes are as follows:
(a) Changes in weight of GFM and the moment changes associated with those weight changes.
(b) The net effect of contract modifications.
(c) Changes in weight of equipment designated as standard for the class and the moment changes associated with those weight changes.
(d) Changes that result from the required use of warranted documentation.
(e) Growth resulting from directed acquisitions.
S3.3.4.7 Separate summaries for each type of change previously listed shall be provided as appendices to the QWR. A GFM summary (see S3.3.4.3) and a contract modification summary (see S3.3.4.17) are required with every submittal of a QWR. Other summaries may be submitted at the option of the contractor to substantiate growth beyond his control. If an optional summary is submitted, it shall document all of the activity for that particular type of change, weight increases and decreases, and modified locations. The ship’s displacement, KG, list, and trim from the contractor-responsible condition shall be compared to the AWE or ABWE values for displacement and KG and the specified allowable ranges for list and trim. Report details shall be grouped in accordance with the three-digit system, and each item shall indicate whether the information shown is estimated, calculated, or based on actual weight determination. The report shall conform to the content and format requirements of S3.3.4.1. In addition, the report shall contain reasons for changes, recommendations to correct any adverse trends, and a listing of all the equipment for which an actual weight determination was performed during the reporting period.
S3.3.4.8 Final Weight Report (FWR)—The FWR shall reflect the final status of the ship design and construction effort that resulted in a delivered product and is normally based on an inclining experiment. All of the reporting requirements of a QWR (see S3.3.4.6) also apply to a FWR. In addition, when inclining experiment full-load displacement and KG values differ from the weight estimate without margin predictions by greater than ½ %, an analysis of the data shall be conducted to reconcile the differences. Findings that result in correction of inaccuracies, reevaluation of factors, and so forth, shall be incorporated in the FWR. The only acquisition margin that may appear in the FWR is building margin. This margin accounts for irreconcilable differences between the weight report and the inclining experiment. The FWR shall contain a narrative that describes the portions of the weight data that are still based on factors, such as paint, weld material, mill tolerance, and so forth, and the criteria that comprise the factors.
S3.3.4.9 Weight Estimate and Report Appendices—The following appendices specified in S3.3.4.10 through S3.3.4.17 provide additional information and background data during the detail design phase.
S3.3.4.10 GFM Summary—The purpose of the GFM summary is to extract from the estimates and reports weight and location data for all GFM and identify the government responsible net weight and moment change that occurs to GFM during detail design. The GFM summaries shall accurately reflect the Schedule A portion of the contract, conform to the content and format requirements of S3.3.4.16, and be included as an appendix to the BIWE or PABWE, AWE or ABWE, each QWR, and the FWR. The baseline for measuring detail design changes is established in the AWE or ABWE. Once accepted, the baseline is only revised when acquisition responsibility is transferred or to correct data that was available to the contractor before the AWE or ABWE, but was inaccurately reported. Weight changes to GFM and the moment changes associated with those weight changes, along with contract modifications and other types of changes beyond the control of the shipbuilder, are deducted from the current full-load condition to arrive at the contractor-responsible condition. Changes to GFM can result from better definition of the baseline items as the
design matures; the addition, deletion, or modification of items by a revision to Schedule A; or a transfer of acquisition responsibility.

S3.3.4.11 Adjustment to Baseline GFM—The weight and moment totals from the GFM summary in the AWE or ABWE shall be the basis for measuring all subsequent GFM changes and shall be known as the baseline values. In cases in which inaccuracies are discovered in the baseline values for which correct data was available to the contractor before submittal of the AWE or ABWE, the weight report details shall be modified to reflect the correct information. In the GFM summary, the baseline values shall be adjusted and the weight and moment effect of the adjustment becomes the responsibility of the contractor. Fig. S3.8 provides a typical example of the accounting procedure for this type of change.

S3.3.4.12 Design Development to Baseline GFM—When design development occurs to items of baseline GFM, the weight report details shall be updated to record current weight and moment data. The contractor is responsible for properly locating the items of GFM throughout detail design. Moment changes resulting from the relocation of GFM to suit design development are not allowable deductions when determining the contractor-responsible condition. The government is responsible for the weight and moment impact of weight changes to baseline items that occur after the establishment of the baseline. An acceptable method of computing government-responsible moment changes is to multiply the net weight change of baseline GFM design development by the centers of gravity from the original or adjusted baseline GFM. These net weight and moment changes are then deducted from the current full-load condition when determining the contractor-responsible condition. Additionally, once a contract modification has been adjudicated, the GFM portion of the change shall be incorporated into a second section of the GFM summary (conforming to the content and format requirements of S3.3.4.16, with the GFM weight and moment values included as adjudicated in the baseline weight column and in the current values. This section will be used to monitor weight changes to GFM after the contract modification has been adjudicated. Any weight and moment changes identified in GFM after adjudication shall be reflected in the current weight column and included with the weight and moment changes that are deducted from the current full-load condition when determining the contractor-responsible condition.

S3.3.4.13 Revision to Schedule A—When Schedule A is revised to add, delete, or modify GFM, the weight report shall be updated accordingly and the changes shall be reflected as current values in the GFM summary. Since these types of changes will usually be implemented by a contract modification, the contractor shall ensure that the weight and moment changes are also reflected in the contract modification summary. However, for the purpose of determining contractor responsibility, the weight and moment impact of contract modifications on GFM before adjudication should not be included with the GFM net changes, since it is already included with the net effect of contract modifications. Any changes in GFM included with contract modifications after adjudication are covered in S3.3.4.12.

S3.3.4.14 Acquisition Responsibility Changes from Government to Contractor—When acquisition responsibility passes from the government to the contractor, the current values and the baseline values for the item shall be deleted from the GFM summary. If the current weight differs from the baseline weight, the contract modification shall reflect the weight difference. Moment changes associated with the weight difference may be computed by using the baseline centers of gravity for the item that was transferred. After the modification has been adjudicated, changes in weight and location are the responsibility of the contractor.

S3.3.4.15 Acquisition Responsibility Changes from Contractor to Government—When acquisition responsibility passes from the contractor to the government, current weight and moment values for the item that appear in the most recently submitted weight report shall be added to the baseline weight and current weight columns of the GFM summary. Contract modifications that cause this type of transfer shall reflect no weight or moment change. Any subsequent weight change shall be treated as routine design development of GFM and becomes the responsibility of the government.

S3.3.4.16 GFM Summary Format—The GFM summary shall be in tabular form with subtotals by the three-digit system, grand totals for current values, and shall include columns containing the following information for each item:

(a) Three-digit system number.
(b) Schedule A item number.
(c) Description of the item.
(d) Baseline weight.
(e) Current estimated, calculated, or actual weight.
(f) Current vertical lever.
(g) Current vertical moment.
(h) Current longitudinal lever.
(i) Current longitudinal moment.
(j) Current transverse lever.
(k) Current transverse moment.

S3.3.4.17 Contract Modification Summary—Before each claim for equitable adjustment in price or delivery or both, asserted pursuant to the changes clause of the contract, an estimate of the net weight and moment change resulting from the contract modification shall be prepared and submitted to the supervisor. The contract modification summary shall reflect these weight and moment impacts as they appear in the details of the weight estimate, for both adjudicated and unadjudicated changes, including field changes. The summary shall consist of all approved changes listed numerically by NAVSEA number and shall include the title, net weight, and moment impact of each change; an identifier that indicates whether the data is adjudicated or unadjudicated; and a grand total representing the net effect of all approved contract modifications. The contract modification summary shall be submitted as an appendix to the QWRs, the ASR, and the FWR. Supporting details for each contract modification shall be incorporated into the body of the weight estimate as soon as the change is approved. Before adjudication of the contract modification, the weight and moment impact of the change as reported in the contract modification summary shall reflect the current values of the supporting details. After the contract modification has been

FIG. S3.8 Example of GFM Summary Format
adjudicated, the supporting details are treated as any other line items in the weight estimate, but the weight and moment effect of the change as reported in the contract modification summary remains at the adjudicated values. The weight and moment impact of the addition, deletion, or modification of GFM to the Schedule A is implemented by a contract modification summary. If acquisition responsibility passes from the government to the contractor, the contract modification summary shall reflect any difference in weight between the current and baseline weight values. Moment changes associated with the weight difference may be computed by using the baseline centers of gravity for the item that was transferred. Changes in weight are the responsibility of the contractor after the contract modification has been adjudicated. Contract modifications that change acquisition responsibility from the contractor to the government shall reflect no weight or moment impact in the contract modification summary.

S3.3.4.18 Supplemental Weight Report—The following supplemental weight report, specified in S3.3.4.19, provides additional information and background data during the detail design phase.

S3.3.4.19 Machinery Weight Report (Nuclear)—A machinery weight report for a nuclear ship design shall be submitted in the category system in accordance with NAVSEA 0900-LP-039-9020. The report shall be divided into two sections. Section I shall contain nuclear machinery items; Section II shall contain the remaining items of the category system. The following summary sheets shall be included:

(a) A listing of a total for each three-digit group within each of the Categories A through M (excluding I). Subtotals shall be listed for each category and a grand total for nuclear propulsion machinery.

(b) Same as (a), except that Sections I and II shall be listed separately with a subtotal for each section, and a grand total for nuclear propulsion machinery.

(c) A listing of a total of Categories A through M (excluding I) for each three-digit group to make a grand total for nuclear propulsion machinery.

The totals for all summaries shall be the same.

S3.3.4.20 Machinery Weight Report Format—The report shall include the following information in tabular form:

(a) Original weight values from the AWE or ABWE for each item.

(b) Current weight of each item.

(c) Current vertical levers.

(d) Current vertical moments.

(e) Current longitudinal levers.

(f) Current longitudinal moments.

(g) Current transverse levers.

(h) Current transverse moments.

When this report is submitted concurrently with the AWE or ABWE, the QWR, and the FWR, it shall reflect the details of the report it accompanies.

S3.3.5 Supplemental Documents—The following supplemental documents when required by the CDRL, provide additional information and background data during the detail design and construction phase.

**NOTES:**
1. Represents summation of adjudicated and unadjudicated values for all contract modifications that were included in the inclining experiment data (including those affecting variable loads).
2. Represents values for net weight and moment changes in GFM since the AWE.
3. These adjustments can include equipment designated as standard for the class changes, changes resulting from the required use of warranted documentation, or growth resulting from directed procurements.
4. Insert tolerances agreed to or limits in Section 070 of the Ship Specifications.

# DESIGN AND WEIGHT DATA SHEET

## USS SAMPLE

### General Data
- **Type:** 4000 miles
- **Endurance:** 4000 miles
- **Trial Speed:** 20.2 knots
- **Complement:** 300

### Hull Characteristics
- **LQA:** 583'3-13/16"
- **LBP:** 529'0"
- **MP:** 264/6"
- **Block Coef.:** 0.491
- **Midship Coef.:** 0.823
- **Waterplane Coef.:** 0.724
- **Volume of Superstructure:** 240,850 ft³

### Displacement and Stability Characteristics
- **Limiting Drafts:** 21'0"
- **Full Load Drafts:** Fwd 19.16', Aft 19.67', Mean 19.42'
- **Limiting KG:** 22.88 (Full Load Cond. D Basic Ship, No Margins)
- **Trim:** 0.51 by stern

### Inclining Experiment
- **Cond. A:** 5929.261, 7905.6
- **Cond. D:** 5929.261, 7905.6
- **KG:** 26.0, 26.2

*Note: Inch-pound units are shown in example, however SI units are applicable when specified.*

FIG. S3.11 Example of Design and Weight Data Sheet Format

22
S3.3.5.6 Weight Distribution Report—A longitudinal weight distribution shall be submitted in a tabulated format in accordance with the standard longitudinal station breakdown. Weight and longitudinal center of gravity shall be determined for each ship station for both light ship and full-load condition. The resultant total weight and longitudinal center of gravity for the weight distribution report shall equal the values reflected in the basic weight estimate or report for the same reporting period.

S3.3.5.7 Electronic Media—Electronic media shall be submitted that describes the applicable reports in the format specified in the Annex and in accordance with the requirements set forth in ANSI X3.4.

S3.3.5.8 Weight and Moment Trade-Off Studies—Trade-off studies comprise various engineering and technical studies directed toward determining detail weight data. These analytical studies are used to support design change proposals and support recommendations for reversing trends toward exceeding established margins or limits. These studies are conducted on an “as requested” basis and contain detailed weight calculations reflecting the impact of the study on ship displacement, KG, list, and trim. There is no fixed format for the weight calculations, but each submittal shall use the ESWBS classification system to structure and summarize the data.

S4. NOTES

S4.1 Issue of DODISS—When this guide is used in acquisition, the applicable issue of the DODISS must be cited in the solicitation (see S1.1 and S1.2).

S4.2 Data Requirements—The following Data Item Descriptions (DIDs) must be listed, as applicable, on the Contract Data Requirements List (DD Form 1423) when this guide is applied on a contract to obtain the data, except when DOD FAR Supplement 27.475-1 exempts the requirement for a DD Form 1423.

S4.3 Reports Interface—The interface of weight estimates and reports is depicted in Fig. S3.11.

S4.4 This guide satisfies a requirement to combine all weight control technical requirements for all phases of U.S. Navy surface ship acquisition contracts into a single document.

ANNEX

(Mandatory Information)

A1. INPUT DATA FILE FORMAT AND TRANSFER

A1. Scope

A1.1 Scope—This annex contains the required format for completing the standard Navy weight report input data files. This annex is a mandatory part of this guide. The information contained herein is intended for compliance (see S4.2).

A1.2 Format—Input data files, when required by the design contract or ship specifications, shall be in accordance with the format specified in Annex A1. In general, for each item in the weight estimate there shall be two lines of data in the file. The first line is mandatory and shall contain information regarding the weight and center of gravity of the item. The second line is optional, depending upon the specification requirements, and shall contain information regarding the inertia characteristics of the item. An example of the Navy standard weight estimate format is shown in Fig. A1.1.

A1.2.1 First Line of Data—The format for the first line of data is as follows:

A1.2.1.1 Columns 1 through 5, Classification Number—Columns 1 through 3 are based on the Expanded Ship Work Breakdown Structure (ESWBS) (see NAVSEA S9040-AA-IDX-010/SWBS 5D). Columns 4 and 5 provide for special subtotals within the classification number. Columns 4 and 5 shall contain only numeric data. Generally, two zeroes are used to designate an ESWBS element title. For example, Main Deck would be designated 13100 for ESWBS. Note that ESWBS subgroups ending in a zero are not to be used for input data, such as 110, 120, 230, 240, and so forth.

A1.2.1.2 Column 6—Column 6 is used for functional category designation when required for nuclear-powered ships. These categories are defined by NAVSEA 0900-LP-039-9020.

A1.2.1.3 Columns 7 through 10, Item Number—The item number provides the means of identification of each line within any five-digit element number. The following rules apply:

(a) Each line shall have an item number.

(b) All titles representing any of the basic ESWBS titles shall include a zero in Column 10.

NOTE: A1.1—Titles for special subtotals within an ESWBS element may contain any item number desired.
FIG. A1.1 Example of Navy Standard Weight Estimate Format
(c) Care shall be taken not to repeat any item numbers within a five-digit element.

(d) Do not use any leading zeroes in the item number, such as 0010.

(e) Item numbers for entries should be entered in increments of ten, such as 10, 20, and 30, instead of 1, 2, and 3.

(f) All item numbers shall be right justified.

A1.2.1.4 Column 11, Station—This column is used in conjunction with the standard longitudinal weight distribution for subsequent strength calculations. For weight distribution, the ship is divided into 22 stations which are lettered A through X (excluding I and O). Station A is designated to contain all items whose longitudinal center of gravity (LCG) is forward of the forward perpendicular. Station B contains all items with an LCG between the forward perpendicular and ship Station 1. Station C contains items between ship Station 1 and ship Station 2, and so on to Station X, which contains all items aft of the aft perpendicular. For each item (except titles and items with no weight), Column 11 shall contain a letter from A through X (excluding I and O), unless one of the following special options is used:

(a) An asterisk inserted in Column 11 for any item indicates the weight will be automatically distributed in a 22–station longitudinal distribution in proportion to the basic hull structure. The basic hull structure for ESWBS consists of Group 1 from 110 through 159, except 114 and 123 through 126. Items in the basic hull structure shall not use the asterisk option.

(b) A digit of 2 through 9 in Column 11 indicates the weight for the given item will be distributed over 2 through 9 stations centered about the item’s LCG. If enough stations are not available to do a particular distribution, the distribution will be done over as many stations as are available. For instance, if a six-station distribution is required within two stations of either end of the ship, then a four-station distribution will occur.

A1.2.1.5 Column 12, Special Designator—This column shall contain designators established by the government. Where no designator is applicable, this column shall be left blank. In the event of a conflict in determining which designator is to be used, the order of precedence shall be by alphabetical order. This designator provides for dual purpose as follows:

(a) Provides for extractions across the entire ship for summaries, such as plates, extruded shapes, weldments, primary, secondary, and others as required. (b) Provides for listing within the three-digit element, such as controls, components, distribution, and others as required.

(c) The following designators are applicable:

   C – Controls, such as valves, switches, regulators, gear boxes, and shutters.

   D – Distribution items, such as ducts, pipe, wire, wireways, connectors, waveguides, propeller shafts, and propeller shaft bearings.

   E – Plating and sheeting.

   F – Forgings, extruded shapes, rolled shapes, built-up shapes, and castings.

   G – Weldments.

   M – Major components, such as air conditioner units, antennas, actuators, batteries, blowers, boilers, compressors, computers, cranes, davits, distillers, transmitters, receivers, transceivers, engines, fans, generators, motors, propellers, pumps, turbines, winches, and replenishment-at-sea (RAS) equipment.

   P – Secondary, peripheral, and interface components, such as hydraulic reservoirs, electrical power supplies, nonintegral tanks, filters, heat exchangers (for system), and subbases.

A1.2.1.6 Column 13, Special Modifier—This column shall contain a modifier established by the government for the Column 12 designator for those items in Groups 1 through 7 only, that is, not including items of variable load. In the event a modifier cannot be determined, a Z shall be inserted. This modifier provides for dual purpose as follows:

(a) Provides for extractions across the entire ship for various material types, such as all steel, all aluminum, and others as required.

(b) Provides for special systems summaries across the entire ship or within certain elements, such as all payload, all habitability, and special systems such as hydrofoils and air cushions.

(c) The following modifiers are applicable:

   A – Aluminum.

   B – Brass and bronze.

   C – Copper, copper-nickel, and nickel-copper.

   D – Ordinary strength steel.

   E – Higher strength steel.

   F – Fiberglass, plastic, and insulation material.

   H – Habitability items, such as berthings, clothing and personal effects stowage, leisure systems, sanitary systems, messing, personal service, utility, and work systems. (This modifier shall supersede any material-type modifiers.)

   J – Wood material.

   K – Liquids.

   L – Lead.

   M – Miscellaneous metallic material.

   N – Miscellaneous nonmetallic material.

   P – Payload, which includes items that are peculiar to the specific missions of a particular ship, such as minesweep gear on a minesweeper, oceanographic gear on an oceanographic ship, and so forth. (This modifier shall supersede any material modifiers.)

   W – Welding, riveting, and fastening.

A1.2.1.7 Columns 14 through 45, Description—These 32 columns shall be used to describe each item adequately. Whatever is entered as input data is reproduced exactly on the weight estimate or report printout. Any combination of alphanumeric characters or blanks can be used. Clear and complete description is essential. However, if budget weights are being used, the description field shall be limited to 24 columns (Columns 14 through 37). Columns 38 through 45 will then be used for budget weights (see A1.2.1.8).

A1.2.1.8 Columns 38 through 45, Budget Weight—Budget weight, if used, is entered in pounds on ESWBS titles only. This allows weight values from 0 to 99 999 999 lbs (to be entered 999999999).

A1.2.1.9 Columns 46 through 53, Unit Weight—Always enter unit weight of any item in pounds. The broken line on the Standard Navy Transmittal Form (NA VSEA 5230/32) between Columns 51 and 52 provides a decimal point, allowing a unit weight up to 999 999.99 lbs. When the unit weight is a whole number, enter two zeroes behind the implied decimal point. If the weight is a deduction, enter a minus sign (–) immediately before the unit weight number.

A1.2.1.10 Columns 54 through 57, Number of Units—Values from 0.001 to 999 units can be entered. This number is multiplied by unit weight to produce total weight for each line item. Unit weight, number of units, and total weight are all printed in the detail output.

A1.2.1.11 Columns 58 through 62, Vertical Center of Gravity (VCG)—These columns shall be used for entering the VCG of each item. The VCGs shall be carried out to the hundredth
decimal place. When the VCG is a whole number, two zeroes must be entered after the decimal point. If the VCG is negative (a weight below the baseline), enter a minus sign immediately before the VCG number. All VCGs are measured in feet. The VCG will be multiplied by the computed total weight, and the resultant vertical moment will be printed.

A1.2.1.12 Columns 63 through 67, Longitudinal Center of Gravity (LCG)—These columns shall be used for entering the LCG of each item. The LCG is measured in feet and carried out to the hundredth decimal place. Always enter a positive LCG; no sign is necessary. When the LCG is a whole number, enter two zeroes behind the implied decimal point. The LCG will be multiplied by the computed total weight, and the resultant longitudinal moment will be printed.

A1.2.1.13 Column 68, LCG Sign—As previously mentioned, the LCG is always entered as a positive value. Enter “F” or “A” to indicate whether the weight is located forward or aft of the longitudinal reference datum. A blank in Column 68 is interpreted to mean “A” or aft.

A1.2.1.14 Columns 69 through 73, Transverse Center of Gravity (TCG)—These columns shall be used for entering the TCG of each item. The TCGs shall be carried out to the hundredth decimal place. When the TCG is a whole number, two zeroes must be entered after the decimal point. All TCGs are measured in feet port or starboard of the centerline, with the exception when port and starboard symmetry exists. If a line item has port and starboard symmetry, the TCG is measured in feet from the transverse center of one side (port or starboard) of the symmetrical item. This is essential to calculate the weight moment of inertia value of the line item. Always enter a positive TCG; no sign is necessary. If the TCG is not applicable, leave Columns 69 through 73 blank. The TCG will be multiplied by the total weight, and the resultant transverse moment will be printed.

A1.2.1.15 Column 74, TCG Sign—As mentioned previously, the TCG is always entered as a positive value. Enter “P” or “S” to indicate whether the weight is port or starboard of the centerline. However, when a line item has port and starboard symmetry about the centerline, enter “X” to indicate the transverse center of one side (port or starboard) of the symmetrical line item. This distance will only be used to calculate the weight moment of inertia value of the line item. A blank in Column 74 is interpreted to mean “P” or port.

A1.2.1.16 Column 75, Reservation Indicator (RES)—This column is used to indicate reservation items or design responsibility. The letter “R” shall be used to designate a reservation item. The letters “A” through “Z” (except “R”) may be used, as required, to indicate design responsibility, such as:

H – Hull design.
M – Machinery design.
E – Electrical design.

A1.2.1.17 Column 76, Reason for Change—This column is used to indicate the reason for change as follows:

0 – Nomenclature change (no weight change).
1 – Contract modification change.
2 – Government-furnished material change.
3 – Change to class status, such as estimated to calculated or calculated to actual.
4-9 and A-Z user-assigned reasons. The column appears under “CHG” in the output.

A1.2.1.18 Column 77, Material Source Indicator—The column is used to indicate the source of an item as follows:

G – Government-furnished material.
F – Contractor-fabricated material.
P – Contractor-purchased material.

A1.2.1.19 Column 78, Class Status—Used to indicate the confidence of the weight value entered for the line item as follows:

E – Estimated weight.
A – Actual scale weight.
V – Vendor or catalog weight (to be changed to “A” upon actual weight determination of the item).

A1.2.20 Columns 79 and 80, Report Number—Enter the report number in which the change was first incorporated. Report Number “AO” shall be used for the first submittal of input. Line items changed before the first periodic weight report shall carry Report Number “BO” for the first such change, “CO” for the second, and so forth. The first periodic weight report shall have Column 79 blank, and a “1” in Column 80, and so forth. Deletions may contain the letters “DD” in Columns 79 and 80, instead of a report number, or the deletion line may be erased.

A1.2.2 Second Line of Data—The second line of data for each item contains the gyradius data for the item and immediately must follow the first line of data in the file. The format for the second line of gyradius data is as follows:

A1.2.2.1 Columns 1 through 5, Classification Number—These columns must contain the same five-digit classification number as the line of weight data that precedes it in the file.

A1.2.2.2 Column 6, I_o Designator—An asterisk (*) must be included in this field to designate the line as a second line containing inertia data for the previous line.

A1.2.2.3 Columns 7 through 10, Item Number—These columns must contain the same item number as the preceding line that contains the weight data for the item.

A1.2.2.4 Column 20, Shape of I_o Item—This field is used to indicate what kind of shape is to be used to estimate the I_o for the weight item. The following are shapes that may be used:

0 – The I_o calculation is to be the ratio or a percentage of a three-digit element's I_o.
1 – The I_o data are actual inertias.
2 – Rectangular prism.
3 – Hollow frustum of a cone.
4 – Hollow right circular cylinder.
5 – Hollow right rectangular cylinder.
6 – Hollow hemisphere.
7 – Square diamond.

Drawings showing the geometry and orientation of Shapes 2 through 7 can be found in Fig. A1.2. If this field is blank or contains a zero, the I_o will be calculated as a percentage of the three-digit element specified in Columns 41 through 50.

A1.2.2.5 Column 25, Orientation of the I_o Shape—This field is used to define the relationship between the local
coordinate system of the \( I_0 \) item as shown in Fig. A1.2 and the ship’s coordinate system. The entries to be used are as follows:

0 – \( X \) axis of the shape as shown in Fig. A1.2 is oriented in the ship’s longitudinal direction.

1 – \( X \) axis of the shape as shown in Fig. A1.2 is oriented in the ship’s transverse direction.

2 – \( X \) axis of the shape as shown in Fig. A1.2 is oriented in the ship’s vertical direction.

**NOTE A1.2**—The orientation of the shape relative to the ship’s coordinate system need not have any sign for the calculation of the inertia. For example, the inertia of the pyramid (Shape 5 in Fig. A1.2) about all three axes is the same whether the point of the pyramid is pointing in the positive \( X \) (to the right) or negative \( X \) direction (to the left). Therefore, for an item that is to be modeled as a pyramid with the point oriented to the stern of the ship, the value to be entered for the orientation in Column 25 would still be “O,” which is the same as if it were pointing to the bow.
A1.2.2.6 *Columns 31–40, X-Dimension*—For each of the shape definitions given in Column 20, the following information must be entered. The format for this field is right justified with an implied decimal point between Columns 38 and 39.

<table>
<thead>
<tr>
<th>Shape (Column 20)</th>
<th>X-dimension (Columns 31–40)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or Blank</td>
<td>Blank or zero means the ratio of current weight to the weight of the specified element (entered in the Y-dimension field) is used to calculate the ( I_x ) or ( I_y ) (if 999 is entered in the Z-dimension field) or both, based on the specified element’s ( I_x ) or ( I_y ) or both. Percentage, which is used to calculate the item’s ( I_x ) or ( I_y ) or both, based on the specified element’s (entered in the Y-dimension field) ( I_x ) or ( I_y ) or both. For 1% enter 100, for 0.05% enter 5, and so forth.</td>
</tr>
<tr>
<td>1</td>
<td>( l_x ) about the local axis oriented in the ship’s longitudinal direction.</td>
</tr>
<tr>
<td>2, 3, 4, 5, 7</td>
<td>X-dimension (A of Fig. A1.2); Blank.</td>
</tr>
<tr>
<td>6</td>
<td>Blank.</td>
</tr>
</tbody>
</table>

A1.2.2.7 For the percentage option (0 or blank in Column 20), there are two possible options for calculating the \( I_x \) or \( I_y \) terms or both. For the first option, the X-dimension field is left blank, and there is a three-digit element number contained in the Y-dimension field. For this case, the \( I_x \) or \( I_y \) for the data line will be calculated as a percentage of the \( I_x \) or \( I_y \) for the specified element. The percentage used will be the weight of the data line to the element weight. If 999 is entered in the Z-dimension field, the \( I_x \) or \( I_y \) will be calculated in a similar manner. If a percentage is inserted in the X-dimension field and a three-digit element number is in the Y-dimension field, the \( I_x \) or \( I_y \) will be calculated as the defined percentage of the \( I_x \) or \( I_y \) for the specified element. If 999 is entered in the Z-dimension field, the \( I_x \) or \( I_y \) will be calculated in a similar manner.

A1.2.2.8 *Columns 41–50, Y-Dimension*—For each of the shape definitions given in Column 20, the following information must be entered. The format for this field is right justified with an implied decimal point between Columns 48 and 49.

<table>
<thead>
<tr>
<th>Shape (Column 20)</th>
<th>Y-dimension (Columns 41–50)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or Blank</td>
<td>Three-digit element on which ( I_x ) or ( I_y ) or both percentage calculation is based. If blank, the calculation will be based on the current three-digit element.</td>
</tr>
<tr>
<td>1</td>
<td>( I_x ) about local axis oriented in the ship’s transverse direction.</td>
</tr>
<tr>
<td>2, 3, 4, 5, 7</td>
<td>Y-dimension (B of Fig. A1.2); Outer Radius (R of Fig. A1.2)</td>
</tr>
<tr>
<td>6</td>
<td>Blank.</td>
</tr>
</tbody>
</table>

A1.2.2.9 *Columns 51–60, Z-Dimension*—For each of the shape definitions given in Column 20, the following information must be entered. The format for this field is right justified with an implied decimal point between Columns 58 and 59.

<table>
<thead>
<tr>
<th>Shape (Column 20)</th>
<th>Z-dimension (Columns 51–60)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or Blank</td>
<td>If blank, only the ( I_x ) calculation will be done using a ratio or an entered percentage. If 999 is entered, then both the ( I_x ) and ( I_y ) calculation will be done using a ratio or an entered percentage.</td>
</tr>
<tr>
<td>1</td>
<td>( I_x ) about the local axis oriented in the ship’s vertical direction.</td>
</tr>
<tr>
<td>2, 3</td>
<td>Z-dimension (C of Fig. A1.2); Inner Radius (r of Fig. A1.2)</td>
</tr>
<tr>
<td>6, 7</td>
<td>Blank.</td>
</tr>
</tbody>
</table>

A1.2.2.10 *Columns 61–70, T-Dimension*—For each of the shape definitions given in Column 20, the following information must be entered. The format for this field is right justified with an implied decimal point between Columns 68 and 69.

<table>
<thead>
<tr>
<th>Shape (Column 20)</th>
<th>T-dimension (Columns 61–70)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 1, 2, 4, 5, 7</td>
<td>Blank.</td>
</tr>
<tr>
<td>3, 6</td>
<td>Thickness (t of Fig. A1.2).</td>
</tr>
</tbody>
</table>

A1.2.2.11 *Columns 79–80, Report Number*—Enter the report number in which the change was first incorporated as described for the first line of data.

A1.3 *General Input Data Requirements:*

A1.3.1 *Load Titles*—Line items for titles shall be prepared for each required load condition, and for each load element comprising that condition, in accordance with ESWBS in the following format:

<table>
<thead>
<tr>
<th>Column 1</th>
<th>Alpha load condition designator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns 2 and 3</td>
<td>Load element number.</td>
</tr>
<tr>
<td>Columns 4 and 5</td>
<td>Zeroes.</td>
</tr>
<tr>
<td>Column 10</td>
<td>Zero.</td>
</tr>
<tr>
<td>Columns 14 through 37</td>
<td>Load element title.</td>
</tr>
</tbody>
</table>

A1.3.2 *Load Details*—Loads for ESWBS are classified in much the same manner as light ship elements in Groups 1 through 7 and follow the same format. Input data must be prepared for all detail load items comprising the full-load condition (F in Column 1). The letters “A” through “L” are used in Column 1 to indicate various other loading conditions.

A1.3.3 *Margins*—Margins for ESWBS are classified in accordance with ESWBS. The weight and moment of each margin will be distributed automatically over the 22 longitudinal stations in proportion to the light ship weight distribution. The margins either can be input as a total weight or as a percentage of total light ship displacement. Line items for margins are prepared in a similar manner to light ship details. The first line item of the margin group shall be a title of the form “M0000—0—Margins,” beginning in Column 1. Margin depletions are handled as negative detail weight entries, in the same manner as light ship details, and follow the same format. Margin options are as follows:

A1.3.3.1 *Option 1, Input Weight*—Enter the total margin weight in pounds in Columns 46 through 53 and centers of gravity as desired. All or any centers of gravity may be left blank. The margins will then be automatically positioned at the light ship centers of gravity.

A1.3.3.2 *Option 2, Percentage*—Margin may be computed as a percentage of total light ship. In the unit weight, Columns 46 through 53, enter the percentage desired (for example: 4% = 4.00). Enter zero in Column 57 of number of units. Centers of gravity may be entered or left blank. If left blank, margins will be placed at light ship centers of gravity.

A1.3.4 *Titles*—Titles for Groups 1 through 7 are included in the Navy program. All other titles shall be prepared by the user. A title shall be prepared for each of the ESWBS elements.

A1.4 *Data Transfer*—Input data files, when required by the contract or ship specifications, shall be transferred on electronic media and in ASCII format.
X1. SUGGESTED FORMS FOR WEIGHT ESTIMATION

X1.1 The suggested forms for weight estimation are shown in Figs. X1.1-X1.8.

**FIG. X1.7 Sample Form #7**
Standard Guide for
Cable Splicing Installations

This standard is issued under the fixed designation F 1835; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (e) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide provides direction and recommends cable splicing materials and methods that would satisfy the requirements of extensive cable splicing in modular ship construction and offers sufficient information and data to assist the shipbuilder in evaluating this option of cable splicing for future ship construction.

1.2 This guide deals with cable splicing at a generic level and details a method that will satisfy the vast majority of cable splicing applications.

1.3 This guide covers acceptable methods of cable splicing used in shipboard cable systems and provides information on current applicable technologies and additional information that the shipbuilder may use in decision making for the cost effectiveness of splicing in electrical cable installations.

1.4 This guide is limited to applications of 2000 V or less, but most of the materials and methods discussed are adaptable to higher voltages, such as 5-kV systems. The cables of this guide relate to all marine cables, domestic and foreign, commercial or U.S. Navy.

1.5 The values stated in SI units shall be regarded as standard. The values given in parentheses are inch-pound units and are for information only.

1.6 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the application of regulatory limitations prior to use.

2. Referenced Documents

2.1 ASTM Standards:
B 8 Specification for Concentric-Lay-Stranded Copper Conductors, Hard, Medium-Hard, or Soft
D 2671 Test Methods for Heat-Shrinkable Tubing for Electrical Use

2.2 IEEE Standards:
IEEE 45 Recommended Practice for Electrical Installations on Shipboard
2.3 UL Standards:
UL STD 224 Extruded Insulating Tubing
UL STD 486A Wire Connectors and Soldering Lugs for Use with Copper Conductors
2.4 IEC Standards:
IEC 228 Conductors of Insulated Cables
2.5 Federal Regulations:
Title 46 Code of Federal Regulations (CFR), Shipping
2.6 Military Specifications:
MIL-T-16366 Terminals, Electric Lug and Conductor Splices, Crimp-Style
MIL-T-7928 Terminals, Lug, Splices, Conductors, Crimp-Style, Copper

3. Terminology

3.1 Definitions of Terms Specific to This Standard:
3.1.1 adhesive, n—a wide range of materials used extensively for bonding and sealing; coating added to the inner wall of heat-shrinkable tubing to seal the enclosed area against moisture. Adhesive is for pressure retention and load-bearing applications (see also sealant).

3.1.2 barrel, n—the portion of a terminal that is crimped; designed to receive the conductor, it is called the wire barrel.

3.1.3 butt connector, n—a connector in which two conductors come together, end to end, but do not overlap and with their axes in line.

3.1.4 butt splice, n—device for joining conductors by butting them end to end.

3.1.5 circumferential crimp, n—final configuration of a barrel made when crimping dies completely surround the barrel and form symmetrical indentations.

---

1 This guide is under the jurisdiction of ASTM Committee F25 on Ships and Marine Technology and is the direct responsibility of Subcommittee F25.10 on Electrical.

2 Annual Book of ASTM Standards, Vol 02.03.

4 Available from the Institute of Electrical and Electronic Engineers, IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, NJ 08854-1331.

5 Available from Underwriters Laboratories, Inc., 333 Pfingsten Rd., Northbrook, IL 60062.

6 Available from the International Electrotechnical Commission, 3 rue de Varembé, Case Postale 131, CH-1211, Geneva 20, Switzerland.

7 Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111–5098, Attn: NPODS.
3.1.6 compression connector, n—connector crimped by an externally applied force; the conductor is also crimped by such force inside the tube-like connector body.
3.1.7 cold-shrink tubing, n—tubular rubber sleeves that are factory expanded and assembled onto a removable core. No heat is used in installation. Also known as prestretched tubing (PST).
3.1.8 crimp connectors, n—tubular copper connectors made to match various wire sizes and fastened to the conductor ends by means of a crimping tool.
3.1.9 crimping die, n—portion of the crimping tool that shapes the crimp.
3.1.10 crimping tool, n—a mechanical device, which is used to fasten electrical connectors to cable conductors by forcefully compressing the connector onto the conductor. This tool may have interchangeable dies or “jaws” to fit various size connectors.
3.1.11 heat-shrink tubing, n—electrical insulation tubing of a polyolefin material, which shrinks in diameter from an expanded size to a predetermined size by the application of heat. It is available in various diameter sizes.
3.1.12 primary insulation, n—the layer of material that is designed to do the electrical insulating, usually the first layer of material applied over the conductor.
3.1.13 sealant, n—inner-wall coating optional to shrinkable tubing to prevent ingress of moisture to the enclosed area (see also adhesive).
3.1.14 splice, n—a joint connecting conductors with good mechanical strength and good conductivity.
3.1.15 tensile, n—amount of axial load required to break or pull wire from the crimped barrel of a terminal or splice.

4. Significance and Use

4.1 Splicing of cables in the shipbuilding industry, both in Navy and commercial undertakings, has been concentrated in repair, conversion, or overhaul programs. However, many commercial industries, including aerospace and nuclear power, have standards defining cable splicing methods and materials that establish the quality of the splice to prevent loss of power or signal, ensure circuit continuity, and avoid potential catastrophic failures. This guide presents cable splicing techniques and hardware for application to commercial and Navy shipbuilding to support the concept of modular ship construction.

4.2 This guide resulted from a study that evaluated the various methods of cable splicing, current technologies, prior studies and recommendations, performance testing, and the expertise of manufacturers and shipbuilders in actual cable splicing techniques and procedures.

4.3 The use of this guide by a shipbuilder will establish cable splicing systems that are: simple and safe to install; waterproof, corrosion, and impact resistant; industry accepted with multiple suppliers available; low-cost methods; and suitable for marine, Navy, and IEC cables.

5. General Requirements for Cable Splicing

5.1 Cable splicing requires that cable joints be insulated and sealed with an insulation equal in electrical and mechanical properties to the original cable. Cable splicing shall consist of a conductor connector, replacement of conductor insulation, replacement of the overall cable jacket, and where applicable, reestablishment of shielding in shielded cables and electric continuity in the armor of armored cables.

5.2 Nonsplice Applications—The only unacceptable area for a cable splice is established by regulations and concerns the restriction of being unable to splice cables in defined hazardous areas. Hazardous areas are locations in which fire or explosion hazards may exist as a result of flammable gases or vapors, flammable liquids, combustible dust, or ignitable fibers or flyings.

6. Cable Splicing

6.1 Cable splicing presented in this guide uses a system of compression-crimp, tubular-metal connectors for butt connection of cable conductors and insulating systems of shrinkable tubing to reinsulate the individual conductors and replace the overall cable jacket.

6.2 Crimp Connectors—For splice connection of conductors, compression-crimped connectors shall be used for joining an electrical conductor (wire) to another conductor. The joint requires proper compression to achieve good electrical performance while not overcompressing and mechanically damaging the conductor. Compression connections are accomplished by applying a controlled force on a barrel sleeve to the conductor with special tools and precision dies.

6.3 Conductor Reinsulation—Thin-wall shrinkable tubing shall be used to reinsulate the conductor and the installed connector. The insulation tubing, when shrunk or recovered, shall be equal in electrical and mechanical properties to the original conductor insulation. Tubing used for conductor reinsulation does not require an interior adhesive sealant coating.

6.4 Cable Jacket Reinsulation—Shrinkable tubing shall be used to envelop the overall splice. To satisfy more abusive conditions that cable jackets are exposed to, a flame-retardant, thick-wall tubing construction with factory applied sealant shall be used.

7. Cable Preparation

7.1 Cables to be spliced shall be prepared to the dimensions specified in Fig. 1 and Fig. 2. Fig. 1 provides cable preparation for power cables from single to four conductor sizes. Dimensions for multiple conductor cables (conductor size of No. 14 or less) are shown in Fig. 2.

7.2 Care must be exercised when preparing the cable ends so that conductor insulation is not cut when removing the overall cable jacket, shield, or cable armor, where applicable. Similar care is required when removing the individual shield or insulation protecting the conductor to prevent cuts or nicks on the individual conductor strands.

7.2.1 Insulation cutting tools that limit depth of cut should be used to prepare cable ends so that underlying insulation is not cut. Similar care is required when removing the individual conductor insulation to protect the conductor copper strands from nicks and cuts.

7.2.2 Cable preparation shall result in stripping the individual conductors so that the bare copper is long enough to reach the full depth of the butt connector plus 3.2 mm (⅛ in.).

**LEGEND:**
- All dimensions are in millimeters (inches are shown in parenthesis).
- Dimension "A" equals half the connector length plus 3 mm (1/8-inch). Bare copper on each conductor equals "A."

*FIG. 1 Splice Dimensions for Power Cables*
7.3 Match the geometrical arrangement between cables to be spliced using conductor color code identification to eliminate crossovers or mismatch when splicing.

7.4 Cable ends shall be in or near their final position before being spliced.

8. Materials and Tools

8.1 Cable Splicing Materials—The following sections provide an overview of the various splice materials. In addition, specific recommendations and suggested guidelines are offered that would enhance the cable splicing process.

8.1.1 Crimp-Type Connectors—Splice connectors shall be compression-type, butt connectors conforming to the requirements of UL STD 486A and shall be satisfactory to Section 20.11 of IEEE 45.

8.1.1.1 Connector shall be seamless, tin-plated copper.

8.1.1.2 Butt connector shall have positive center wire stops for proper depth of conductor insertion.

8.1.1.3 Connectors shall be marked with wire size for easy identification.

8.1.1.4 Connector shall have inspection holes to allow visual inspection for proper wire insertion.
8.1.1.5 Butt connector for wire sizes No. 10 (AWG) or larger shall be the “long barrel” type to permit multiple crimps on each side of the connector for greater tensile strength. The conductor ends shall be fully inserted to the “stop” at the center of the connector. For smaller conductor sizes (No. 10 AWG or less), a single crimp should be spaced half way between the end of the connector and the center wire stop.

8.1.1.6 Connector shall be color-coded in accordance with Table 1 or Table 2.

8.1.2 Conductor Reinsulating Material—To reinsulate the conductor and the installed connector, heat-shrink tubing shall be used. (see Table 3).

8.1.2.1 When recovered or shrink, the tubing used shall be equal to or greater than the thickness of the original conductor insulation.

8.1.2.2 Shrink tubing used for conductor reinsulation shall be heat-shrink tubing. The tubing shall be thin-wall cross-linked polyolefin tubing, flame-retardant (FR-1) construction in accordance with UL STD 224 requirements. Performance requirements shall include:

- Shrink ratio: 2:1
- Operating temperature range: –55 to +135°C
- Minimum shrinkage temperature: +121°C
- Longitudinal shrinkage: ≤5%
- Electrical rating: 600-V continuous operation
- Dielectric strength in accordance with Test Methods D 2671: 7.9 kV/mm (200 V/mil) min

8.1.2.3 Shrink tubing to cover the connection of individual conductors does not require an interior coating of adhesive (mastic) sealant.

8.1.3 Cable Jacket Replacement Materials—Several methods and a variety of materials are available that will provide the mechanical protection, moisture-sealing properties, and electrical performance characteristics needed in a cable splice. For a splice reliability and ease of installation replacement of cable jacket and to envelop the splice area, however, either the heat-shrink or the cold-shrink (prespun) type shall be used.

8.1.3.1 The tubing used, when recovered or shrunk, shall be equal to or greater than the thickness of the original conductor insulation (see Table 3).

8.1.3.2 The tubing used for cable jacket replacement shall be thick wall, also referred to as heavy-duty shrink tubing used for rejacketing of cables.

8.1.3.3 Shrink tubing shall be flame retardant (FR-1) in accordance with UL STD 224 requirements.

8.1.3.4 Tubing used for rejacketing of a splice bundle shall have an interior coating of adhesive (mastic) sealant.

8.1.3.5 Table 3 provides dimensions for thick-wall tubing used for rejacketing of cables.

8.1.3.6 Tubing shall have the following performance requirements:

- Shrink ratio: 3:1
- Operating temperature range: –55 to +135°C
- Minimum shrinkage temperature (for heat-shrink tubing): +121°C
- Longitudinal shrinkage: ≤5%
- Electrical rating: 600-V continuous operation
- Dielectric strength in accordance with Test Methods D 2671: 7.9 kV/mm (200 V/mil) min

8.1.4 Shield Terminations—Cables that require continued shielding shall have at least a 13-mm (1/2-in.) overlap between the replacement shielding material and the permanent shielding and shall be attached with either solder-type connectors or a mechanical connection using inner and outer compression (crimp-type) rings.

8.2 Splicing Tools:

8.2.1 Cable Preparation—The basic tools required for cable splice preparation include a cable cutter, measuring tape or ruler, and a wire insulation stripper. Following the cable preparation, the types of tools required to complete a cable splice include:

a Recommended colors for connectors; however, variations do exist between manufacturers.

b For conductors No. 1 or larger, the type of crimping tool used determines the number of crimps to be made. Number and location of compression points (crimps) shall be in accordance with the manufacturer’s recommendations.
splice include the crimp tool for compression of the butt connectors and a heat source for reducing heat-shrinkable tubing.

8.2.2 Crimping Tools—The crimp compression method for making electrical cable splices as recommended in this guide consists of compressing a butt connector onto the wire very tightly so that good metal-to-metal contact is achieved. A crimping tool is necessary so that the process is controlled, the crimp is made easily and correctly and can be reproduced reliably.

8.2.2.1 This guide recommends the use of compression systems that coordinate connectors, crimping tools and dies, and include built-in installation and inspection features that prevent improper field connections.

8.2.2.2 The crimping tool shall be a single-cycle type, requiring full-cycle compression before release. Full-cycle control requires that the crimping tool to be closed to its fullest extent, thereby completing the crimping cycle before the tool can be opened.

8.2.2.3 Mechanical-type (manual) compression tools used for crimping connectors shall be a one-cycle device and require full compression before release.

8.2.2.4 Hydraulic crimping devices shall have an emergency release mechanism to abort the crimp cycle if necessary.

8.2.2.5 Crimp tool shall allow easy visual field check for proper tool adjustment with butting surfaces.

8.2.2.6 Crimping tool and crimp dies shall result in circumferential-shaped configuration.

8.2.3 Heat Guns—Heat-shrink tubing installation requires that the source of heat be controllable. Limited electric heat guns and hot air blowers that are portable and provide even controlled heat at nozzle temperatures of 260 to 399°C (500 to 750°F) are recommended devices for installing heat-shrink tubing. Propane torches shall be used with extreme care. Torches shall not be used to shrink thin-wall tubing.

9. Quality Assurance

9.1 General Guidelines for Quality Assurance—For extensive cable splicing activities, such as found with modular ship construction techniques, it is recommended that a material control program and a personnel training program that includes certification of personnel for both splicing installation and inspection. Quality control issues are of major significance and factors that can be controlled and monitored by the shipbuilder before, during, and following cable splicing. A cable splicing program as envisioned for modular ship construction should include use of only approved materials and devices, only qualified personnel to make the electrical cable splices, and establish inspection procedures, using only qualified inspectors, to verify proper installation.

9.2 Material Control—Since crimping is a mechanical process and, by controlling the material and dimensional properties of the conductor, the butt connector, and the crimp tool, the reliability of the crimped connection may be controlled closely. An in-process quality assurance program based on controlled distribution of materials and tools should be established. For installation tools, the program should include inspections to assure that:

9.2.1 Splicing equipment shall be inspected before the first use each month to verify the performance of insulation removal devices and of crimping tools.

9.2.2 Crimp tool dies shall be checked before the first use each month for correct tolerances.

9.3 Material Procurement; Recommended Use of Kits—A material control program should adopt the use of cable splice kits. Splice kits may be procured directly from a number of manufacturers.
qualified manufacturers or can be assembled by the shipbuilder from quantity-purchased materials for the various types and sizes of materials necessary. All kits shall be for one-to-one cable splices. For selection of cable-splice kit, the following minimum information should be established:

9.3.1 Number of conductors in the cable,
9.3.2 Size (gage) of each conductor,
9.3.3 Ground wire size, if included,
9.3.4 Shielded or nonshielded; individual, overall
9.3.5 Only one splice per kit is recommended, with basic materials of the kit to include butt connectors, conductor reinsulation material, cable jacket replacement material, and shield braid sleeve connectors, when required.

10. Installation

10.1 Installation Guidelines—Various factors and conditions are significant in contributing to a successful splice. These items are summarized in this section as installation guidelines for the use of shipbuilders and others. These basic factors should be emphasized in any quality assurance or training programs established in support of a major cable splicing program.

10.2 Splice Locations—There are no significant differences in installing vertical splicing and horizontal splicing, however after splicing is completed on a cable, the cable should be supported as close as possible to the splice. For extensive splicing at section interfaces, it is recommended that individual cable connections be staggered and where appropriate, the cables fanned out from one row to a double row for space to ease installation and avoid derating of cables.

10.3 Important Splicing Factors:

10.3.1 The crimping device shall be matched properly to the splice connector and wire size.
10.3.2 Splicing material should be kept as clean as possible during application so that foreign matter or contaminants are not within the splice. Lightly abrade and solvent clean the cable jacket a minimum of 153 mm (6-in.) from the jacket cutback edge.
10.3.3 Proper installation requires that the shrink tubing should be centered over the installed splice connector, conductor reinsulation material, cable jacket replacement material, and shield braid sleeve connectors, when required.

10.4 Dimensions:

10.4.1 Length of the replacement insulation tubing shall be 57.2 mm (2 1/4 in.) longer than the butt-crimp connector length (see Table 1 and Table 2).
10.4.2 The replacement jacket shall overlap the original cable jacket by either 76.2 or 101.6 mm (3 or 4 in.) min at each end as shown in Fig. 1 or Fig. 2.
10.4.3 Shrink-tubing dimensions shall be as shown in Table 3 for conductor reinsulation or for cable jacket replacement.

10.5 Heating—For heat-shrinkable tubing, apply heat and begin shrinking at the center of the tubes and move toward the ends. For jacket replacement, apply heat at the center of the tube and toward each end until the tube is smooth and wrinkle-free and recovered enough to assume the final configuration. When a fillet of adhesive is visible at each end, discontinue heating. Additional heating will not make the tube shrink tighter.

10.6 Inspection Checkpoints—For quality control and the assurance of a splicing program, there are a number of checkpoints at which inspections can be made to verify proper installation of the cable splice. These include steps in preparation for, during the overall splice process, and post-inspection following completion of a splice.

10.6.1 The following suggests various checkpoints in the splicing process that a quality assurance inspection program could include:

10.6.1.1 Cable ends are properly positioned, that is, staggered configuration and prepared properly to dimensions for size and number of conductors that will be spliced.

10.6.1.2 Splices are assembled properly, positioned in the crimp tool, and crimped.

10.6.1.3 Verify the use of an approved, complete-cycle crimping tool with dies matched to the splice connector and conductor.

10.6.1.4 Verify that the splice connectors are spaced properly.

10.6.1.5 Connectors are insulated properly.

10.6.2 Following conductor insulation replacement, the verification process should include inspection that:

10.6.2.1 All tubings are shrunk in place permanently.

10.6.2.2 All insulation tubings meet the overlap requirements for conductor replacement.

10.6.2.3 Tubings are not nicked or split or charred if heat-shrink tubing was used.

10.6.3 Post-Splice Inspection—Following the completion of a cable splice, post-splice inspections also can be undertaken to check the splice quality. Some checkpoints that should be considered in an inspection program are:

10.6.3.1 Verification that jacket tubing meets the minimum overlap requirements.

10.6.3.2 Verification that the jacket replacement tubing is shrunk permanently in place without damage, such as cut or split.

10.6.3.3 Adhesive should be visible at each end for heat-shrink tubing used in cable sheath replacement.

10.6.3.4 That replacement armor is positioned and secured properly or a jumper is installed to maintain electrical continuity for splices made in armored cable.

10.6.4 For heat-shrink with integral (encased) shield for splicing of shielded cables, the following apply:

10.6.4.1 Sleeve/shield must be recovered along its entire length.

10.6.4.2 Sleeve must be recovered tightly around cable jacket.

10.6.4.3 Sealing rings must have flowed along cable jacket.

10.6.4.4 Sleeve must not have discolored to the degree that joint cannot be inspected.

10.6.4.5 Strands must not be poking through the sleeve.

10.7 Additionally, the shipbuilder has the final inspection checkpoint in that, as part of the standard shipboard tests for cable installations, that is, for continuity and for resistance to ground (insulation resistance), electrical performance of the completed splices shall be tested.

11.1 cable splicing; crimp connectors; circumferential crimp; electrical cable splicing; insulation sleeving

APPENDIX

(Nonmandatory Information)

X1. ADDITIONAL INFORMATION ON CABLE SPLICING SELECTION AND PERFORMANCE CONSIDERATIONS

X1.1 Background

X1.1.1 A number of studies have evaluated available splicing materials and techniques that would support extensive cable splicing mandated in modular ship construction. These investigations affirmed that suitable materials and several installation techniques are available for the various shipboard applications that exist and that these splicing systems would guarantee the integrity of spliced cables to be the equal of a continuously installed cable.

X1.2 Marine Cable

X1.2.1 In the U.S. shipbuilding industry, commercial vessels are constructed typically with IEEE 45-type cables or U.S. Navy military specification cables. Naval combatants and auxiliary ships typically use the Mil Spec cables. Additionally, commercial merchant vessels use a PVC/nylon insulated cable derived from a standard building wire-type construction, as well as a wide variety of nonstandard cables listed by Underwriters Laboratories, Inc. under the Marine Shipboard Cable Program. Foreign vessels typically use cable constructed in accordance with International Electrotechnical Commission (IEC) requirements. These international standards govern the construction and installation of electrical cables on merchant ships and on a general comparison with U.S. practices (IEEE 45 or Mil Spec) are found to be comparable and without significant differences in design.
X1.3 Connectors

X1.3.1 Commercial Versus Military Specification Connectors—A difference in minimum performance requirements of the splice crimp connectors exists between commercial and Mil-Spec-type connectors. The tensile strength requirements for crimped connectors most widely used are those specified in UL 486A or as required in Military Specifications in accordance with MIL-T-7928 or MIL-T-16366.

X1.3.1.1 Comparison of the minimum pull-out force test values listed in these documents shows that, in general, the specified requirements for the Mil-Spec are twice that of the values specified in UL STD 486A.

X1.3.1.2 Tensile strength or minimum pull-out force is the measure of the pulling force required to destroy the crimped connection (joint) between conductors; however, destruction may not necessarily occur at the crimp joint and may occur in one of the following ways:

(a) Slip of the wire from the crimped connector.
(b) Slip of some strands, rupture of the others at the crimp joint.
(c) Rupture of the wire at the crimp joint.
(d) Rupture of the wire outside of the crimped termination.

X1.3.1.3 Although IEEE 45 and the Code of Federal Regulations Title 46 recommends the use of connectors listed by UL STD 486A, this guide adopts that crimp butt connectors used for the marine shipboard environment should have minimum requirements exceeding the basic commercial requirements. The more stringent requirements defined in the military specification certainly are more appropriate to guarantee the mechanical connection between conductors.

X1.3.2 Crimp Configurations—The crimp die of the tool determines the completed crimp configuration. There are a variety of configurations in use, such as a simple nest and indent die, or the more complicated four indent die. Several different configurations may work equally well for some applications, while for others, a certain shape is superior. Since cable splicing for modular construction would require extensive splices at section interfaces for multiple cable runs (banks), therefore, the area (volume of splices) required should be minimized to the maximum extent possible. The optimal technique to fulfill this requirement is the use of the circumferential compression of butt connectors. Circumferential-shaped compression applies equal force around the connector sleeve and results in each conductor strand receiving equal compression and carrying an equal amount of current loading. This type of joint eliminates loose strands, and therefore, is virtually free of electrical-caused noise. In general, connectors compressed into a circumferential joint will have a higher pull-out strength and a lower electrical resistance than the common indented (bathtub) crimped connector. For the best results and to satisfy minimum splice area, a circumferential-shaped compression applying equal force around the sleeve should be used. Note, however, that to assure positive joints, each connector for this type of operation is designed for only one or a very limited number of conductor sizes.

X1.4 Splicing Systems
